(*Motion No 21*) Chairman Hogstad was requested to revise and submit the recommendations for final consideration, on motion of Arny Hayman and he and his associates were given a vote of appreciation for the success of the recent observance

62 *A Ph A -N A R D Joint Committee* Secretary Kelly reported for the three A Ph A delegates that it was planned to have a meeting of the Joint Committee as soon as convenient to the N A R D delegates At the present time, no definite report could be submitted The meeting then adjourned to meet at 7 30 P M

(Evening Session)

The attendance was the same as for the afternoon session with the exception of H A B Dunning who was called away

63 *Reduction in Nominees for the Presidency* The nomination and election of officers of the ASSOCIATION was considered at length

(*Motion No 22*) It was moved by Arny that the Council recommend to the Special Committee on Constitution and By-Laws that the nominees for president, and for first and second vice president be reduced from three to two in each case The motion was seconded by Costello and carried with Fischelis voting in the negative

(*Motion No 23*) It was moved by Philip seconded by Holton and carried that the Council recommend to the Special Committee on Constitution and By-Laws, that the By Laws be so amended as to authorize and direct the Council to fill any vacancies that may occur by resignation sickness, death or otherwise in the list of nominees for the mail ballot

64 *Committee on Proprietary Medicines* The secretary reported that J H Beal had declined because he could not undertake the work, to act as chairman or as a member of the Committee and the chairman stated that as the membership has been elected by the Council in session he did not feel authorized to fill the vacancy by appointment (Council Letter No 1 JOURNAL, August 1935, page 706, Items 13 and 14)

(*Motion No 24*) Roy B Cook was elected Chairman of the Committee on motion of Costello, seconded by Delgado and carried

H H Schaefer was elected a member of the Committee on motion of Fischelis seconded by Arny and carried

65 *Approval of N F VI* The secretary reported that bound copies of the book would be mailed on December 9th to the members of the Council and to the members of the Committee on N F for formal approval in advance of the release of the book for distribution on December 16th

Two unbound copies were submitted to the members present for inspection

(*Motion No 25*) It was moved by Swain that the Council approve the work of the Committee on National Formulary as represented in the printed copies of N F VI submitted, and authorize its publication The motion was seconded by DuMcz and carried

66 *Resolution by the N A R D* President Costello read the following letter addressed to him by Secretary Dargavel

'At the annual convention of this ASSOCIATION held in Cincinnati September 23rd to 27th, a resolution was adopted commending Dr E F Kelly for his work on the National Retail Drug Code Authority and following the instructions of the convention we are advising the officers of the AMERICAN PHARMACEUTICAL ASSOCIATION through you of this action

"WHEREAS, the work of Dr E F Kelly as secretary of the National Retail Drug Code Authority was of inestimable value to members and officers of the N A R D and the retail pharmacists of the United States

"Be It Resolved, that the N A R D in convention assembled express its appreciation and thanks to Dr E F Kelly in person and to the AMERICAN PHARMACEU-

TICAL ASSOCIATION for making his services available and that the officers of the AMERICAN PHARMACEUTICAL ASSOCIATION be advised of this action

"The National Association of Retail Druggists appreciates the very splendid effort of Dr Kelly in regard to this work, and also permit me to state that in my opinion it has been the most outstanding work that the AMERICAN PHARMACEUTICAL ASSOCIATION has done in so far as commercial pharmacy is concerned in its history I trust that this letter and resolution will be called to the attention of all the officers of the ASSOCIATION"

(Signed) JOHN W DARGAVEL, *Secretary*

(*Motion No 26*) It was moved by Arny, seconded by Hayman and carried, that the letter be spread on the minutes of the Council

67 *Recommendation No 1 in the President's Address* Chairman Hilton called attention to the fact that consideration of the recommendation was taken up at the reorganization meeting of the Council in Portland and referred to this meeting of the Council A general discussion of the recommendation and of its application followed It was pointed out that Dr Kelly's services to the Maryland Pharmaceutical Association did not require the assumption of administrative activities or extensive absence from his Washington office

(*Motion No 27*) It was moved by Hayman that the secretary be given permission to serve as secretary of the Maryland Pharmaceutical Association if he is requested to do so The motion was seconded by Holton and carried

68 *Election of Members* The following applications were submitted

No 102, Isaac F Harris, The Harris Lab, Inc Tuckahoe, N Y, No 103, Anna S Hoffmann, 98 First Ave, Atlantic Highlands, N J, No 104, Sister Constance Ryan, 365 Sixth Ave, S, Fargo, N Dak, No 105, R R Muntz, Box 1060 Jamestown, N Dak, No 106, Cyril H Mergens, 226 W Rosser Ave, Bismarck, N Dak, No 107, Charles Hersey, Rugby, N Dak, No 108, Joseph P Cutting 207 Main St, Williston, N Dak, No 109, Carl F Kaz, Gackle, N Dak, No 110, Robert Wm Elich, 2310 N Sawyer Ave, Chicago, Ill, No 111, Leonard W H Charnock, 20 E Delaware Pl, Chicago, Ill, No 112 Ray Gist, 1709 Ruby St, Pullman, Wash, No 113, William Engle, 11 Wave Ave, Beachmont, Mass, No 114, August Merz, c/o Calco Chemical Co, Bound Brook, N J, No 115, Albert Greenlees, Methodist Hospital, Houston Texas, No 116, Lillian Herforth Bowen, 130 N Wells St, Chicago, Ill, No 117, Elmer K Walters, 5th and Main Sts, Richmond, Va, No 118, David Jacobson, 701 N 28th St, Richmond, Va, No 119, Joseph Allegetti, 1201 W Grand Ave, Chicago, Ill, No 120, Paul P Famular, 3696 Boulevard, Jersey City, N J, No 121, George L Rumbaugh, 8231 Ingleside Ave, Chicago, Ill, No 122, Charles O Wilson, University of Washington, Seattle, Wash, No 123, Abraham Kruger, 375 Osbourne Terr, Newark, N J, No 124, Henry Louis Debus, Main St, Peapack, N J, No 125, Theodore P Koszalka, 95-06 99th Ave, Ozone Park, N Y, No 126, Saul Rosin, 8701 91st Ave, Woodhaven N Y, No 127, David Shapiro, 663 Miller Ave, Brooklyn, N Y, No 128, Reuben Cheron 275 Hooper St, Brooklyn, N Y, No 129 Herbert B Camis, 101-66 94th St, Ozone Park, N Y, No 130, Olga Julia Berzetas, 9132-79th St, Woodhaven N Y, No 131, Samuel S Katz, 267 Oak St, Perth Amboy, N J, No 132, Oscar S Schwartz, 1034 Hoe Ave, New York, N Y, No 133, Alexander Hollander 140 W 98th St, New York, N Y, No 134, William B Day, 1229 E Dennison St, Davenport, Iowa

(*Motion No 28*) On motion of Cook, seconded by Hayman and carried, the applicants named above were elected members of the ASSOCIATION

69 *Recommendation No 9 in the President's Address* In discussing this recommendation, Dr Fischelis called attention to the value of the 'Professional Pharmacy' to the Boards of Pharmacy in connection with their work in regulating the stock and equipment in drug stores No action was taken on the recommendation

70 *Recommendation No 14 in the President's Address* The secretary reported that this recommendation had been brought to the attention of the chairman of the Committee of Revision of the U S P and it was the opinion that such action as is necessary should be taken jointly with the U S P authorities

(*Motion No 29*) On motion of Fischelis seconded by Arny and carried, the chairman was authorized to appoint a special committee of the Council to study this matter and to cooperate with any committee appointed by the U S P Board of Trustees or Committee of Revision

71 *Recommendation No 17 in the President's Address* Treasurer Holton reported that consideration had been given to the recommendation and submitted the following statement as indicating the money available from the various permanent and trust funds

LIFE MEMBERSHIP—The available accumulated income, since 1920, amounts to \$5843 57
EBERT PRIZE—Income restricted to award

CENTENNIAL—Income to "aid in the prosecution of original investigation "

ENDOWMENT—Income not available until fund amounts to \$25 000 00 when 50% of the income may be used for any purpose deemed wise by the ASSOCIATION Now \$17,020 23

EBERT LEGACY—Income not available until fund amounts to \$10,000 00 and then "shall be devoted to such purposes as will in the opinion of the Council best commemorate the founder of the fund and his services to pharmacy " Now \$8760 76

RESEARCH—Income limited to honoraria and awards

PROCTER—Trust fund

REMINGTON—Trust fund

He concurred in Chairman Philip's statement that it was too early to estimate what might be appropriated from the Current Fund during 1936 toward the inauguration of the activities mentioned

(*Motion No 30*) On motion of Fischelis seconded by Philip and carried, the secretary was requested to list pending activities in the order of their importance and to apply funds now available or which may become available later to their execution

72 *Articles of Incorporation of the A Ph A* Mr Philip submitted the results of his investigation of the incorporation of the ASSOCIATION in 1888 It was requested that the study be continued and that a report be submitted as promptly as is possible for such action as may be required and for the guidance of the Committee on Constitution and By-Laws

73 *Complimentary and Review Copies of N F VI* The secretary reported that in addition to the copies of N F VI in leather which were being sent to the members of the Committee on N F and to the members of the Council, Chairman Gathercoal had submitted a list of those to whom it was recommended that copies of the N F in cloth should be sent as a token of appreciation for their services during its preparation and that the Committee on Publications had submitted a list of pharmaceutical medical and other publications to whom it was recommended that copies in cloth should be sent for review

(*Motion No 31*) On motion of Swain, seconded by Eberle and carried the recommendations with respect to complimentary and review copies of the N F VI were concurred in

As it was impossible to complete the program on account of the lateness of the hour the meeting was adjourned at 11 40 P M, with the understanding that the remaining items of business will be submitted by mail

If any members of the Council desire to submit corrections of the minutes of this meeting, they are requested to do so promptly

E F KELLY *Secretary*

"A COMPARISON OF THE RATIOS OF WISCONSIN DRUG STORES AT THE TIME THE STATE PHARMACY LAW WAS PASSED AND AT PRESENT ""

This is one phase of a study of organized pharmaceutical activity in Wisconsin 1880-1930 The number of drug stores in each of the present ten congressional districts is tabulated with the population of that district and the ratio computed The congressional district was chosen as a unit because it is the most satisfactory unit for most if not all of the states

It is of interest to note that in 1862 the ratio was 1 2418 and that a few years ago it was practically the same, viz 1 2498 To draw the inference, as has been done that the pharmacist of to day is therefore as well off financially as he was half a century ago involves a grave misuse of statistics

* Abstract of a paper before Section on Commercial Interests, A Ph A, Portland meeting 1935—by Minnie Meyer and Edward Kremers

COMMITTEE REPORTS

REPORT ON THE TWELFTH INTERNATIONAL CONGRESS OF PHARMACY

BY EDGAR ERSKINE HUME *¹

Mindful of the honor done him, though not a pharmacist, by being appointed Delegate on the part of the United States to the recent International Congress of Pharmacy, the writer feels it a duty to give the information that he gathered at this interesting and important Congress to the pharmaceutical profession of the country. His report to the Secretary of State is therefore given in its entirety, being published with the permission of that officer and of the writer's military superior, the Surgeon General of the Army.

The Twelfth International Congress of Pharmacy was held at Brussels, Belgium, from July 31, 1935, to August 5, 1935, inclusive. The sessions were all held at the University of Brussels, several miles distant from the center of the city, with the exception of certain social features.

The Congress was divided into sections, most of which met separately. Some of these sections were in turn subdivided into subsections, but only for committee work. The following were the sections, with the presidents and secretaries of each.

First Section *Pharmacognosy and Galenic Pharmacy* President, Prof N Wattiez of the University of Brussels, Secretary, Pharmacist G LaGrange

The following topics were considered by the section the presentations being made as indicated.

Official Badge of Major Hume as Delegate of the U S to 12th International Congress of Pharmacy

1 "Contribution to the Chemical Study of the *Sapoteae* of the Belgian Congo. The *Omphalo carpum* Boysankombo." By Dr L Adriaens of the Chemical Research Laboratories of the Belgian Congo.

2 "*Trichisia Gillelts*, Staner." By E Castagne, Engineer Chemist of the Chemical Research Laboratories of the Belgian Congo.

3 "The Alkaloids of the *Liane Esire*." By Pharmacist Delvaux of the University of Louvain.

4 "The Essential Oil of the Wallflower and of Patchouli from the Belgian Congo." By Dr P Denis of the Chemical Research Laboratory of the Belgian Congo.

5 "The Oil of *Euphorbia palustris*." By Prof Paul Gilho of the Faculty of Pharmacy of Nancy.

6 "On the Spectrophotometric Dosage of the Alkaloids of the Ergot of Rye by the Reaction of van Urk." By Prof F Sternon of the University of Liège and Juliette Rensonnet.

7 "Study of the Unification of the Methods of the Preparation of the Heroic Galenic Vegetable Medicaments." By Prof H Golaz of Lausanne.

8 "Critical Studies of the Methods of Dosage of Alkaloids in the Official Preparation of Belladonna of the Belgian Pharmacopœia." By Prof N Wattiez, of the University of Brussels and Pharmacist Gaston LaGrange.

9 "Opinion Concerning the Standards of the So Called Chaulmoogra Oil for International Acceptance." By Prof E Perrot of the Faculty of Pharmacy of Paris.

10 "Contribution to the Study of the Seeds of *Sirophanthus Congolais*." By Louise Ghénne Assistant in the Institute of Pharmacy of the University of Liège.

Second Section *Pharmaceutical Chemistry* President, Prof A Castille of the University of Louvain, Secretary, Pharmacist L Delvaux.

The following topics were considered by the section, the presentation being made as indicated.

* Delegate of the United States to the Twelfth International Congress of Pharmacy, Brussels, Belgium, 1935.

¹ Major, Medical Corps, U S Army, Librarian, Army Medical Library, Washington, D C

- 1 "Flowing Potentials and Absorptive Power of Barium Sulphate The Role of Colloid Buffers of the Saponines" By Prof Ruyssen of the University of Ghent
- 2 "Titration of Alkaloids in Alcoholic Solution" By Prof Baggesgaard Rasmussen of the Royal Pharmaceutical College of Copenhagen
- 3 "Spectrographic Research on the Alkaloids of Cinchona and Their Derivatives" By Prof van der Wielen of the University of Amsterdam
- 4 "Nucleic Acid in the Ergot of Rye" By Prof M Marck Gatty Kostyal, of the University of Crakow, and J Tesarz
- 5 "The Question of the Dielectric Constant in Problems of Chemical Constitution of the Organic Compounds in Relation to Their Pharmacodynamic Action" By Kazimierz Kalinowski (Poland)
- 6 "Dakin's Solution of the Different Pharmacopœias Analysis and Stability" By Colonel J Thomann, Chief Pharmacist of the Swiss Army Instructor at the University of Bern
- 7 "Preparation and Stability of Dakin's Solution (Sodium Hypochlorite)" By Svend Aage Schou of Hellerup (Denmark)
- 8 "The Dosage of Hydrastine, Scopolamine, Hyoscyamine, Eserine and Apiole by the Mercurimetric Method" By Prof Al Ionescu Matiu of the University of Bucharest and Dr C Popesco
- 9 "Halogen Analogues of Ephedrine and Adrenaline" (Presentation in English) By W H Linnell, M Sc, of London
- 10 "The Stability of Strophanthin Solutions" (Presentation in English) By B Berry, B Sc, of London

Third Section *Chemical Analysis and Toxicology*, Joint Session

Fourth Section *Bromatology* President, Prof F Schoofs of the University of Liège
Secretary, Dr H Lecoq of the University of Liège

The following topics were considered by these sections, the presentations being made as indicated

- 1 "Limits in the Use of the Conductometric Method for the Determination of Bases and Weak Acids" By Konstanty Hrynakowski, of the University of Poznan (Poland) and Feliks Modzejewski
- 2 "The Application of Potentiometric Titration in Pharmaceutical Analyses" By Dr Oldrich Tomicek, Professor at the University of Prague (Czechoslovakia)
- 3 "Contribution to the Iodometric Control of Medicaments" By Prof L Maricq of the University of Brussels
- 4 "The Application of the Determination of the Electrical Conductibility in the Examination of Waters" By J Baldewyns of Liège
- 5 "Titrimetric Colorimetry" By Prof D van Os of the University of Groningen (Netherlands) and Dr P Karsten
- 6 "The Toxicity of Certain Insecticides" By Prof F Schoofs of the University of Liège
- 7 "Phytopharmacy" By V Estienne
- 8 "Removal of Impurities by Barium Carbonate" By Pharmacist A Defalque of the Laboratory of Biochemistry of the University of Louvain
- 9 "A New Stabilized Antidote for Poisoning by the Heavy and Toxic Methods" By Prof Casimir Stryzowsky of the University of Lausanne
- 10 "A Case of Grave Alimentary Saturnism" By Prof A Castille of the School of Pharmacy of the University of Louvain
- 11 "Quantitative Analysis of the Derivatives of Barbituric Acid A Modification of the Method of Determination in an Alkaline Medium" By Kazimierz Kalinowski (Poland)
- 12 "Diabetic Bread" By Dr T Potjewijd Pharmacist of Leyden
- 13 "Spectrographic Study of the Waters of the Region of Spa" By Prof R Vivario of the University of Liège, and P Swings Assistant
- 14 "Analytical Differentiation of Cane Sugar from Beet Sugar" By Pharmacist Herbert of Cairo (Egypt)

Fifth Section Omitted

Sixth Section *Microbiology* President, Prof A J J van de Velde of the University of Ghent, Secretary, Mlle (Pharmacist) Marg van Hauwaert of the University of Ghent

The following topics were considered by the section, the presentation being made as indicated

1 "The Legal Regulation of the Manufacture of Therapeutic Scrums and Various Products of Organic Origin" By Prof A Astruc and Louis Astruc

2 "Experimental Pathogenic Action of the Actinomyces" By Prof A Sartory of the Faculty of Pharmacy of the University of Strassburg, R Sartory and Jacques Meyer, Assistants

3 "Influence of Various Acid and Alcohol Bodies and of Scrums on the Mutation of the Tubercle Bacillus in Culture Media" By Prof A Sartory of the Faculty of Pharmacy of the University of Strassburg, R Sartory, Jacques Meyer and Mlle Renard, Assistants

4 "Qualitative and Quantitative Determinations of Proteolytic Ferments Contained in the Gastric Juice, by the Interferometric Method" By Prof A Sartory of the Faculty of Pharmacy of the University of Strassburg, R Sartory and Jacques Meyer Assistants

5 "On the Necessity of Sterilizing Medical Supplies" By Prof Bronislaw Koskowski of the University of Warsaw

6 "Bacteriological Appraisal of Modern Tooth Pastes and Mouth Washes" (Presentation in English) By Dr Eugene Maier of Giessen (Germany)

7 "Study of the Fertility of the Soil on Dosage with Phosphorus and Potassium, by Means of Sterigmatocystis Nigra (Method of Niklas)" By Prof A J J van de Velde of the University of Ghent

Representation

"A I have been thus far, unable to obtain from the Secretary of the Congress a list of the countries represented or the total number of delegates This information will be reported later if ascertained Estimated number of delegates present (or at least persons who attended the sessions) 500 Estimated number of countries represented 30

B American delegation I was the only delegate from the United States"

Results of the Conference Resolutions Adopted (1) *Phytopharmacy*—Upon the motion of Prof V Estienne of the University of Louvain, the following was adopted "Regulations should be elaborated for the manufacture, conditioning, dispensation and control of toxic products used in agriculture and horticulture This Congress desires that this resolution be transmitted to the governments represented The Congress believes that it is the duty of every pharmacist to be actively interested in pharmacotherapeutics in collaboration with regional agriculturists"

(2) *The Necessity of Sterilizing Medical Equipment*—Upon the motion of Prof Bronislaw Koskowski of Warsaw, the following was adopted A pharmacy, as a sanitary institution, must be careful not to become a place where contagion may be spread The installation must be aseptic The use of glass coverings for the tables and counters, as well as the sterilization of the glassware used in the pharmacy tends to give the impression of the greatest cleanliness, and inspires general confidence One should anticipate the orders of the sanitary authorities that pharmacies be kept aseptic"

(3) *Price Regulation of Specialties Justified by Organized Chemical and Biological Control*—Upon the motion of Pharmacist Breugelmans of Belgium the following was adopted

'I The pharmaceutical profession should be organized corporatively in order to safeguard the scientific, professional and economic interests of its members

"II In consideration of its great advances the pharmaceutical profession should be organized so as to allow the pharmacist to face the requirements of analytical control in conformity to the legal regulations in effect in various countries

"III Professional obligations in this field being assured, monopoly in the sale of materials, and normal profits should be respected

"IV On account of the present extent of university instruction in most countries, the pharmacist has control of chemical products only

"V Since pharmacists have not had the necessary training in such countries, for the examination of biological products, opotherapeutic agents or other materials requiring clinical tests, it is necessary that they have the assistance of qualified assistants with university training in pharmacodynamics and biology

"VI On account of the immensity of the task, there should be created a sufficient number of laboratories for the chemico biological testing of products in order to carry out the examinations required by law

"VII These independent laboratories should be established by the organized profession and under state supervision The State, unable legally to assume responsibility for sale, is able to stimulate and encourage private establishments working in accordance with public health needs

"VIII Organized pharmacy should create, equip and conduct its testing service for a moderate charge, in order to compensate to a certain extent for the cost of maintenance

"IX The State should take over, prior to their establishment, the control of such institutions to insure uniformity and the maintenance of high standards

"X In emergencies, and at first, there might be allowed modifications in the university program, when the need arises, registered pharmacists should be qualified to assume the duty of testing biologicals, having pursued courses of instruction at affiliated laboratories "

(4) *Regulation of Pharmaceutical Responsibility*—Upon the motion of M de Koritsansky and Dr (Pharmacist) Tauffer of the Hungarian Pharmaceutical Association, the following was adopted

"A committee of six members shall be appointed to study minutely and procure data concerning the responsibilities of pharmacists in various countries, and prepare recommendations regarding such regulations The report of this committee shall be considered at the forthcoming meeting of the International Pharmaceutical Federation (*Fédération Internationale Pharmaceutique*) and the decision reached shall thereafter be submitted to the ensuing International Congress of Pharmacy and then brought to the attention of the various national associations forming part of the International Federation Thus such national associations will be able to take the necessary steps with their respective governments to regulate the legal responsibilities of pharmacists "

(5) *Freedom in the Fixing of Charges by Organized Pharmaceutical Services*—Upon the motion of M Pattou, President of the *Nationale Pharmaceutique*, the following was adopted

"Since the representatives of thirty National Associations of pharmacists agree upon the desirability of freedom in the matter of fixing charges, *it is resolved*

"I That patients treated in their homes should be authorized to procure drugs at any pharmacy that accepts the conditions of organization

"II That fees for the furnishing of medicines for patients treated in their homes by organized services cannot be standardized without the collaboration and agreement of the interested associations of pharmacists

"III That fees for persons in moderate circumstances should be reduced, taking into consideration living conditions in each country

"IV That associations of pharmacists, wholly interested in compliance with the established tariffs and in the careful compounding of prescriptions, should be organized to assume proper technical control of this work and in the observance of the professional oath

"V That there should be established an impartial board for arbitration and the prevention of differences that might arise between organized pharmaceutical services and individual pharmacists

"VI In consideration of the faithful collaboration of organized pharmaceutical services, all laboratories with pharmaceutical workers established by social insurance agencies and similar organizations, should be prohibited in those places where organized pharmaceutical services exist "

(6) *Medico-Pharmaceutical Combinations*—Upon the motion of Pharmacist Breugelmans of Brussels, the following was adopted

"Since medicine and pharmacy are professions based on different university training, the pharmacist alone is qualified to perform pharmaceutical work Pharmacy is a profession of the greatest public utility and of the greatest possibilities, it should therefore be encouraged in regions where it does not flourish Pharmacy should justify its existence legally, scientifically and morally, so that it cannot be replaced by a depot of medicaments dispensed by a physician or by any person outside of both professions That combinations of medicine and pharmacy must be considered as detrimental in all places where there is a registered pharmacist That license for the practice of medicine combined with the dispensing of drugs must be strictly regulated and in

such manner as to prevent or restrict all operations for profit by the collusion of the two professions "

(7) *Uniform Laws in All Countries Regarding the Sale of Drugs*—Upon the motion of Pharmacists H Portisch, O Hoyer and F Schweder of Vienna, the following resolutions were adopted

"I That a definition of the word 'medicament' be required as preliminary to every law concerning the healing art

"II That the word 'consumer' must be limited and defined

"III That the 'distributor' be no other than a pharmacist, and that no person be interposed between the producer and consumer who is not a pharmacist

"IV That, with the exception of a few dietetic products, the sale of medicaments be limited to pharmacists

"V That the production (manufacture) of drugs be reserved to pharmacists or to authorized institutions conducted by pharmacists

"VI That the sale of specialties and drugs by wholesale dealers be limited to authorized pharmacists

"VII That the production of drugs be in normal amounts as superproduction is an actual danger to the public "

(8) *The Organization of Military Pharmacists in European Countries*—Upon the motion of Pharmacist Barthet of France, the following was adopted

"That the British delegates to this Congress present to their government a report on the organization of military pharmacists in Europe, Great Britain being the only European country that does not have military pharmacists "

(9) *Inspection of Pharmacies in Various Countries*—The following conclusions by Pharmacist C J Ravaut, of France, were received and transmitted to the International Pharmaceutical Federation for study

"I Inspection of pharmacies is absolutely indispensable for the preservation of public health

"II It should not be limited only to technical control, but also should comprise detection and prosecution of illegal practices

"III Such inspection should be entrusted to pharmacists chosen from among professors of the schools or faculties of pharmacy or from among recognized practitioners skilled in inspection

"IV That the inspectors should be appointed directly by the government, that they should be permanent and have extensive powers to enable them efficiently to perform their duties

"V It is desirable that government authorities be assisted by a Consultative Council representing various elements of the pharmaceutical profession of the nation "

(10) *A New System of Pharmaceutical Education*—Upon the motion of Dr of Medicine and of Pharmacy Alexander Moszony of the University of Budapest, the following was adopted

'In each country where it is necessary, the International Pharmaceutical Federation should envisage a restriction in the number of pharmacists trained, in accordance with national exigencies "

(11) *The Role of Pharmacists in Civilian Defense against Gas*—Upon the motion of Prof Wester of Holland and Pharmacist Weil of Brussels, it was resolved

'That the XII International Congress of Pharmacy, recognizing the services rendered in all countries by pharmacists in defense against chemical warfare, expresses the following requests

'I To Universities To enlarge their courses in analytical chemistry, toxicology and bromatology by more thorough study of war poisons, and that the faculties of pharmacy organize courses for supplementing the knowledge of persons who received their diplomas from said universities in the past

"II To National Red Cross Societies That an important place be reserved for pharmacists in educating the population (courses of instruction for litter-bearers), in the study of means of passive defense applied to aid for victims, and in the mobilization of the Red Cross

'III To Governments That national and regional organizations utilize on a large scale the skill of pharmacists for which their studies particularly qualify them, in the general organization for the detection of gas, disinfection and inspection of gas masks, management of shelters and the conservation of chemical and pharmaceutical products "

(12) *Methods of Elaborating Pharmacopœias*—Upon the motion of Pharmacist Van Huffelen of the Society of Pharmacy of Antwerp the following conclusions were recommended, but not adopted

"I Since for major reasons, pharmacists are included in the commissions on pharmacopœias, it is hoped that all governments will adopt measures necessary to assign to such work, practicing independent pharmacists

"II Since the contact between pharmacopœia commissions and the organized pharmacists must be maintained not only before but also during the elaboration of and preparation of new additions of such pharmacopœias,

"III We recommend that various governments bring home to physicians the importance of a knowledge and use of the most recent edition of the pharmacopœia "

(13) *An International Pharmacopœia*—Prof van Itallie offered the following considerations on Pharmacist Van Schoor's (Antwerp) recommendations Prof van Itallie's recommendations were adopted by the Congress as follows

"The Sixth general meeting of the International Pharmaceutical Federation, held at The Hague, September 6 and 7, 1927, accepted, without discussion, the following proposition

"I The general meeting shall nominate a commission composed of seven members charged with presenting a report on the possibility of publishing a restricted international pharmacopœia

"II This commission will forward its report within the next six months to the bureau of the Federation The latter will present it to the Belgian Government and to the Hygiene organization of the League of Nations

"The full report of this commission, of which Prof van Itallie was *president* and A Scham melhout *secretary*, was published in Bulletin No 1, 1928, pp 11-20 It was addressed to the above authorities Up to the present time we have not heard whether any resolution or decision has been reached on this report

"The Brussels Conference of 1925 on heroin derivatives asked for the appointment of two commissions by the League of Nations, one to determine methods of analysis, the other for the study of galenic medicaments These two commissions have not yet been created Of the persons recommended for places on these commissions some are no longer with us and new members should be designated by duly constituted organizations The needs that brought forth our report in 1928 still exist, and the recommendations are renewed

"With a sufficient desire a restricted international pharmacopœia may be elaborated in time "

(14) *Abolition of Restrictions on Narcotics*—Dr of Pharmacy Chieffo of Rome reported that "Legislation is very different in various countries As concerns a system of regulation the pharmacist should demonstrate sufficient moral qualities to prevent his being compromised as to the improper dispensation of narcotic drugs Limitation of production of such drugs is suggested as the only means of preventing abuses "

The report was submitted for consideration to the International Pharmaceutical Federation

Important Points on Which No Agreement Was Reached

These have been mentioned in the last paragraph, being chiefly recommendations of various delegates that were not passed by the Congress

Publications—The Secretary General of the Congress promised that minutes would be sent each delegate who had subscribed the required fee I did so, but so far no minutes have come to hand The only available publication of the Congress is the program issued in advance, which is transmitted herewith

Part Taken by the American Delegation—The writer, the only American delegate not being a pharmacist in any sense of the word, was able to take no very active part in the sessions For interest he inquired of the representatives of a number of other countries to ascertain if physicians were among their number As far as he could learn he was the only physician of the Congress, except certain men who held degrees in both medicine and pharmacy or one of its branches

The writer who is Librarian of the Army Medical Library, was able to discuss the matter of scientific publications and their cost That the Army Medical Library, the largest medical

library in the world, indexes articles from journals of pharmacy in its *Index Catalogue*, the world's standard of bibliography in the medical sciences, was a matter of pride to the pharmacists of other nations. A number of delegates promised to send material as a gift to the Army Medical Library, and some of this has been received.

Action Taken by the Conference with Regard to Future Meetings—There is no question as to the continuance of the International Congresses of Pharmacy, which have a fixed place particularly in European countries. Article IX of the Rules of the Congress require the final session to select and announce the date and place of the next Congress. The President, however, announced that though more than a dozen countries had extended invitations for the next meeting, it was deemed advisable to give the matter further thought. It was therefore voted that the place and date of the next Congress would be left to the Committee of the International Pharmaceutical Federation (*Fédération Internationale Pharmaceutique*).

General Comment Importance of the Conference—The Congress was a worth-while gathering of some of the world's best scientists in the field of pharmacy in the European sense of the term, that is, the broad topics of chemistry (inorganic, organic and physiologic), pharmacology, bacteriology, serology, biology etc. There was nothing in the conference that pertained to pharmacy as the mere compounding of drugs. The problems of the production of medicinal plants, the mining or other acquisition of inorganic compounds, the manufacture of biologicals, the testing of these various products, were considered. The representatives of most of the European countries were professors at the several universities or research institutions. But little attention was paid to the purely commercial side. The general subject of costs of manufacture was discussed in passing, but only in relation to its bearing on pure science. In other words the meeting was unlike what in this country would be expected at a meeting of certain pharmaceutical associations.

The meeting is believed to have been an important one. From conversations with delegates from other countries I gained the impression that the International Congresses of Pharmacy are held to be among the most important of gatherings of scientific men. Again and again the opinion was expressed that the United States might add much to the meetings by sending professors from the leading universities, men who could present America's views in these fields. In this country, as far as I have been able to learn, there are no scientific bodies comparable to this International Congress. Here to bring together men of these varied interests it would be necessary to have a joint meeting of pharmacologists, chemists and bacteriologists.

One striking difference in the functions of the pharmacist in Europe and in this country is seen in the status of the pharmacists in the Continental armies and that of the United States. In the United States Army the term pharmacist implies merely a trained enlisted man capable of compounding prescriptions. In Europe it means a highly educated professional man. The European Armies nearly all have Corps of Pharmacists distinct from the Medical or Administrative Services. In our Army much of the work that the pharmacist officers do in Europe is performed by medical officers. This includes the routine diagnostic laboratory procedures, general sanitation, and to a limited extent the production of biologicals.

The American delegate quitted the Congress with the feeling that it is to the advantage of the United States to be represented at future International Congresses of Pharmacy. They are old and well-established meetings and much valuable information is to be had by those attending, particularly by personal contacts. Some of our distinguished authorities in pharmacology and pharmacy would be able, on the other hand, to add much to the meetings.

Since the meetings are conducted in French, it seems highly desirable that persons attending the Congress be familiar with that language. Those without a knowledge of French might enjoy the social functions but would get little out of the scientific sessions, and also be unable to discuss matters of common interest with delegates from other lands.

Miscellaneous—There were a large number of social events in connection with the Congress. The King and Queen of the Belgians attended the opening session. (The closing paragraph of the report is largely concerned with conditions and entertainments and therefore omitted.—*Editor*.)

INTERNATIONAL PHARMACEUTICAL FEDERATION

The officers of the International Federation are *President*, Dr J J Hofman, The Hague Holland, *General Secretary*, Dr Potjewijd, Leyden, Holland, *Secretary* Oscar Van Schoor, Antwerp, Belgium

A communication has been addressed to the ordinary members of the International Pharmaceutical Federation in which it is stated that a letter had been transmitted to the authorities of the Countries represented in the 12th International Congress of Pharmacy, containing the conclusions on certain questions which were discussed by the Professional Section and it is suggested that if the problems presented are of interest to the Countries represented that the governmental authorities be asked to study the conclusions arrived at

The communication received is signed by President J J Hofman and General Secretary T Potjewijd under date of November 28 1935 It is addressed to the *Minister of Hygiene and Public Health* Another letter follows to the ordinary members of the International Pharmaceutical Federation and to co members

Charles H LaWall was appointed delegate to the meeting of the International Pharmaceutical Federation and to the 12th International Congress of Pharmacy held in Brussels July 30 to August 5, 1935 Conditions over which the appointed delegate had no control made it impossible for Professor LaWall to attend

Major Edgar Erskine Hume, Medical Corps, United States Army, was the only delegate of the United States present, but not officially designated a representative of the AMERICAN PHARMACEUTICAL ASSOCIATION He has submitted a report on the 12th International Congress of Pharmacy to the AMERICAN PHARMACEUTICAL ASSOCIATION for publication in the JOURNAL It precedes

COMMUNICATION TO THE MINISTER OF HYGIENE AND PUBLIC HEALTH

'The 12th International Congress of Pharmacy which has held a convention at Brussels from July 30 to August 5, 1935, has entrusted the International Pharmaceutical Federation, with headquarters in The Hague, with the mission of transmitting the decisions of the Congress to the Governments of the 29 Nations which participated in the Congress and are represented in the International Pharmaceutical Federation

"It is in pursuance of this mission and to comply with obligations formally placed upon us that we have the honor, Mr Minister, to transmit to you expressions of opinion on three questions which are under the direct supervision of your Department

"These three questions are of great interest for all the Countries spoken of above

"For this reason we have decided to group all three in order to bring the expression of our views to the knowledge of the Governments having members in the International Pharmaceutical Federation

"In consequence, Mr Minister, we have the honor to call your attention very particularly to these views They were discussed at length and conscientiously before their adoption, which was by the unanimous vote of the members of the Congress present at the sessions of Wednesday, July 31st and Friday, August 2nd

"We are asking our members and affiliates of your Country to see that you also receive the reports upon which the resolutions adopted by our meetings were based These reports, which are concise and drawn up in accordance with the regulations of the Congress, give only a general idea of a doctrine familiar to us as professional persons but are sufficient to justify the views expressed by the Congress of which the following is a textual statement

"*First Question*—Adoption of uniform laws in all countries tending toward a rigorous regulation of commerce in medicaments

"1 That the definition of the word medicament is necessary as a preliminary of any law concerning itself with the healing art

"2 That the word consumer should also be equally well defined and limited

"3 That the distributor cannot be any other person than a pharmacist no other person than a pharmacist shall be permitted to interpose himself between the producer and the consumer

"4 That the sale of medicaments, with the exception of certain dietetic products, shall be reserved to pharmacists

"5 That the production (manufacture) of medicaments should be reserved to pharmacists or to institutions enjoying previous authorization and directed by pharmacists

"6 That the sale of medicaments and specialties by wholesalers should be limited to sale solely to authorized distributors, namely, pharmacists

"7 That the production of medicaments should be held to normal requirements, as over-production constitutes a real public danger

"*Second Question* Duplication of Professions —Believing that medicine and pharmacy are two separate professions, requiring different university preparation

"That the pharmacist alone is qualified to exercise the profession of pharmacy,

' That pharmacy is a profession of public utility and that its diffusion in regions now deprived of it is necessary in as large a degree as possible,

"That pharmacy justifies its existence legally scientifically and morally, and cannot be replaced by a depot of medicaments attended by a physician or by some person belonging to neither of the two professions,

"That the union of the practice of medicine with a pharmaceutical depot should be considered as an abuse in any locality where there is a regularly established pharmacist,

"That the license to practice medicine, joined with that to deliver medicaments, should be strictly regulated everywhere in order to prevent or prohibit any operations for profit which may be realized by the union of the two professions into one

* "Accordingly The desire is expressed that the limitation and separation of the two professions should be provided for by law, in accordance with the professional groupings and with a view to the interests of the public health

' *Third Question* —Control of specialties and regulation of sale price

"1 Pharmacy should be corporatively organized in order to safeguard the professional scientific and economic interests of its members

"2 In view of the excessive development of pharmaceutical specialties, the organized profession of pharmacy should take collective action to have the pharmacist permitted to assume the obligation of analytical control of specialties, according to the legal requirements in force in each country

"3 Having assured the observation of professional obligations in this respect, the organized corporation should provide that the monopoly of sale of the specialty and a normal profit in such sale be respected

"4 In the present state of the knowledge which can be acquired at universities in most countries, the pharmacist can only be assured of chemical control of specialties

"5 From the fact that the pharmacist has not received the desired preparation in these countries to enable him to effect, competently control of biologic, opotherapeutic or other compositions necessitating a clinical test recourse should be permitted upon occasion to qualified assistants to be chosen from university graduates who have specialized as pharmacodynamists or biologists, and who have their diplomas as such

"6 In view of the enormity of the task, there should be created a sufficient number of chemico biological laboratories, which will be specialized in view of the multiplication of collaborations made necessary by the division of labor

"7 These autonomous laboratories will function by the initiative of the organized profession and under the supervision of the Government The Government, unable in law to assume any responsibility for the seller, is qualified to stimulate and encourage private initiatives acting in conformity with the requirements of the public health

"8 The organized profession of pharmacy will undertake to create, equip and rent its control services, levying a light tax on the interested parties to compensate itself in some measure for its pecuniary outlay

"9 The Government will require control of all specialties, prior to their registration, by the services of the corporation, in order to assure the conformity of such specialties to their formulas and to legal requirements in regard to their preparation conservation, etc

"10 In the meanwhile it is urgently necessary to strive for modifications in university courses in pharmacy, wherever it may be necessary, in order that graduates may receive a pharmaceutical diploma enabling them to exercise biological control, after instruction and a practical laboratory course in competent institutions

We express the hope, Mr Minister, that you will give our communication your attention and that you will recognize the public interest in the above propositions, all of which are in absolute conformity with the interests of the public health

Requesting you to receive Mr Minister, the assurance of our great consideration,
 ' For the International Pharmaceutical Federation,

The *Secretary*,
 T POTJEWIJD

The *President*,
 J J HOFMAN "

Letter to the Ordinary Members of the International Pharmaceutical Federation

Leyde November 28, 1935

Gentlemen and Honored Co members

We are enclosing a letter which we have sent to the Authorities of the Countries represented in the 12th International Congress of Pharmacy

As you will see from this letter it contains the conclusions on certain questions which were discussed by the Professional Section

If you consider these problems to be of interest to your Country, we suggest that you urge your governmental authorities to study the conclusions arrived at here

Please accept, Gentlemen and Honored Co members, the assurance of our most sincere esteem

The *Secretary General*
 (Signed) T POTJEWIJD

The *President*,
 (Signed) J J HOFMAN

S 3084 PHARMACY

The bill referred to under title was introduced by Senator Copeland and discussed at Portland by the A P H A A A C P and N A B P It is considered a basis for a model pharmacy law and it is suggested that legislative committees obtain copies for consideration R L Swann discussed the measure and speaks of it as a sane and deliberate approach to better legislation controlling the sale and distribution of drugs and medicines and builds greater safeguards around the practice of pharmacy "

OBITUARY

FREDERICK WILLIAM MEISSNER

Frederick William Meissner, of La Porte, Indiana for many years active in the AMERICAN PHARMACEUTICAL ASSOCIATION and a regular attendant at its meetings died December 7th aged 76 years. The following brief biographic sketch is taken from the records of the Chicago Veteran Druggists' Association (1930) of which Mr Meissner has been an associate member since 1909.

"Frederick William Meissner was born in La Porte Indiana, December 5, 1859, he received his education in the public and private schools of that city and began his pharmaceutical career October 13, 1874, taking a position with Dr Ehel Sons. In 1878, due to ill health he went West and in Denver, Colorado took employment with the Huyck's Drug Store. Returning to La Porte in 1879 he again engaged with Dr Ehel Sons until they sold the pharmacy to Dr A U Morris.

"In 1881, he was employed with H K Metcalf & Co 172 N Clark St, Chicago. In the spring of 1882 he returned to La Porte and in association with J H Henry Kuehne took over what had been one of the branch stores of the Dr Ehel Sons and conducted the same under the firm name of Kuehne and Meissner until the spring of 1886, when Mr Meissner disposed of his interest in the firm and entered Philadelphia College of Pharmacy from which he was graduated in 1888. In the fall of the same year he opened a new pharmacy in La Porte, and has conducted the business continuously in the same location up to the present time."

Mr Meissner was a former member of the U S P Board of Trustees, served as president of Indiana Pharmaceutical Association was one of the organizers of the National Association of Retail Druggists and member of its Executive Committee. He served on the Auxiliary Committee of the National Formulary V. He joined the AMERICAN PHARMACEUTICAL ASSOCIATION in 1890 and was chairman of the Section on Commercial Interests 1901-1902. For a number of years he was president of the La Porte City School Board.

The deceased is survived by his widow who accompanied her husband to many of the annual meetings of the A P H A.

ANTOINE EDWARD GREENE

Antoine Edward Greene, professor of Pharmacy at Howard University College of Pharmacy, Washington, D C, died November 30th, aged thirty three years.

Professor Greene was born in Cambridge, Mass, son of Charles and Annie E Greene. He graduated from Massachusetts College of Pharmacy in 1922 and attended Massachusetts Institute of Technology in 1923, 1925 and 1926, in 1924, he was a student at the University of Paris (France). In 1922 he was appointed assistant in Bacteriology, under Dr Algernon B Jackson School of Medicine, Howard University. January 1924, he was named instructor in Theory of Pharmacy and Associate Professor of Pharmacy in 1926, which position he held at the time of his death. He attended the Summer Sessions at the University of Michigan, College of Pharmacy, 1929-1930, and at the University of Wisconsin, 1932-1933.

Professor Greene was a member of the AMERICAN PHARMACEUTICAL ASSOCIATION since 1930, and during these years contributed a number of papers, published in the Scientific Section of the JOURNAL and in the Department of American Association of Colleges of Pharmacy.

James H Breasted, the noted Orientalist and Egyptologist who passed away December 2nd, was at one time engaged in pharmacy, he graduated in 1886 from the Chicago College of Pharmacy—the College of Pharmacy of the University of Illinois.

John B Michels, El Paso, Illinois, a former president of the Illinois Pharmaceutical Association and for many years Mayor of his own city, died December 5th.

DEATH OF FORMER PRESIDENT L L WALTON

L L Walton, president of the AMERICAN PHARMACEUTICAL ASSOCIATION, 1925-1926 died December 26th, following an illness extending over a period of several months, he had been in poor health for a year or more. Sympathy is expressed at this time and a sketch will appear in the January number of the JOURNAL.

PERSONAL AND NEWS ITEMS

Wishes for a Successful 1936

H K Mulford was tendered a dinner at the Union League on October 31st, by the National Drug Club in honor of his completion of 50 years in pharmaceutical work

C C Harris, of Houston, has resigned as *President* of Texas Pharmaceutical Association B B Brown, of Dallas, is the *First Vice President*

Martin E Adamo, a fellow-member has been appointed a member of the Advisory Board of the Division of Immigration and Americanization, under the Department of Education

Among the highlights of the National Drug Trade Conference were Endorsement of fair trade legislation, fair trade enabling act Copeland bill, collection and compilation of evidence relating to harm or danger to public health in the present system of distributing medicines at retail

Dr Raymond A Pearson, former president of the University of Maryland has been appointed special assistant to Rexford G Tugwell

Officers of Ohio Valley Druggists' Association are *President*, Philip A Schwartz, *Vice-President*, Chester A Lathrop, *Secretary*, Stanley Roth, *Treasurer*, Otto E Kistner

Members of the AMERICAN PHARMACEUTICAL ASSOCIATION were ably represented at the St Louis meeting of the American Association for the Advancement of Science and several of the papers received front page recognition in the press Among the latter, papers by John C Krantz, Jr, C Jelleff Carr, Ruth Musser, William Harne James C Munch, Theodore Koppányi, James M Dille Charles R Linegar No doubt others of those mentioned on page 943 of the November JOURNAL received related mention, but at this late day their contributions did not come to this writer's attention

The Texas Centennial will open at Dallas, June 6th Here in August the 84th meeting of the AMERICAN PHARMACEUTICAL ASSOCIATION will be held

BOOK NOTICES AND REVIEWS

A Text-Book of Medical Jurisprudence and Toxicology By JOHN GLAISTER, MD, D PH, FR S E, in collaboration with JOHN GLAISTER, JR, M B, CH C, M D D Sc Fifth edition Published by William Wood and Company New York City, 1931, xv + 954 pp, 132 illustrations and 7 plates \$10 00

Glaister has been an authority in medical jurisprudence and toxicology for the last half century in England American students are probably less familiar with this authority The first sixteen chapters of the fifth edition deal with medical jurisprudence the various British laws and Scotch criminal procedure nature of evidence identification pathological changes in drowning, hanging, electrocution exposure, apoplexy and following various types of wounds, blood stains and identification pregnancy abortion, infanticide drunkenness and lunacy A very large number of case reports are presented to illustrate various phases of medical jurisprudence and 117 figures set forth various features Photomicrographs of various types of hair, post-mortem appearances following wounds methods of identity by finger prints are clearly illustrated

The second section deals with toxicology definitions of poisons poison schedules, the Dangerous Drugs and the Therapeutic Substances Acts and the procedure to be followed in cases of suspected poisoning The last three chapters deal with irritant poisons, arsenic phosphorus various halogens, the opium alkaloids, cannabis, cocaine and a number of vegetable alkaloids A portion of the last chapter discusses food poisoning botulism, snake bites, stinging fishes and arrow poisons The world tolerances for arsenic are discussed but the Manchester Beer poisoning receives only brief mention Characteristic responses from exposure to toxic doses of various poisons as well as abstracts of a number of legal cases of murder with various types of poison (Crippen, Smith, Lyons McCracken Cotton, Cross etc) are described in some detail This will prove a very helpful book for analysis and legal presentation of toxicology —JAMES C MUNCH

The Seventh American Scientific Congress was held in Mexico City September 8th-17th, in the Palace of Fine Arts It was opened by the President of the Republic of Mexico Various American countries were represented by delegates The work of the sections was divided into physical and methodical sciences, geology engineering and industrial chemistry agricultural sciences, biological sciences, medical sciences, hygienical sciences, anthropological and historical sciences, social and economic sciences, and bibliography Indianism juridical sciences

A number of interesting papers were read and the AMERICAN PHARMACEUTICAL ASSOCIATION was represented by Guillermo G Colin and Manuel Donde Gorozpe.

THERAPEUTICS

Acetylthetamethylcholine Chloride—Use of, in Treatment of Neurogenic Bladder and Allied Conditions Preliminary favorable results of acetylthetamethylcholine chloride in a series of patients with neuropathic disturbances of the bladder indicate that this drug may be a valuable addition to the management of these conditions which have been proved very resistant to previous methods of treatment —J T GERNOW, E E EWERT and R D HERROLD *Med Rec* 141 (Feb 1935), 141 (B S R)

Adrenal Cortex Hormone—Effect of, on Hypertension and on Cardiovascular System In cases of hypertension, some complicated by cardiac arrhythmias the administration of adrenal cortex hormone resulted in an abrupt drop in blood pressure and in a clearing up of the arrhythmias —E M JOSEPHSON *Med Rec*, 141 (Mar 1935), 250 (B S R)

Benzylephedrine—Use of, as Analgesic in Chaulmoogra Injections A mixture containing 80-cc chaulmoogra oil, 20-cc olive oil and 0.1 Gm benzylephedrine base is used for intramuscular injection It is painless and has a tolerance 2-3 times that of ordinary chaulmoogra preparations —C T FANG *Chinese Med J*, 48 (1934), 563, cf *C A*, 24 (1930), 4855, through *Chem Abstracts*, 29 (1935), 289

Bismuth Violet—Use of, in Malaria and for Chancroids Approximately 4000 intravenous injections of bismuth violet were given in about 400 cases including all forms of malaria during the past four years Disappearance of the parasites was prompt and complete, with few recurrences A case is reported in which the local application of 0.4 per cent bismuth violet in 10 per cent glycerin aqueous solution and 1 per cent bismuth violet ointment to chancroids over the external genitalia and anus, was followed by prompt relief of pain, arrest of the infection and healing of the lesions On the thirteenth day all ulcers were healed, the inflammation and discomfort were gone and there was practically no scarring —C E WATSON *South Med Surg*, 97 (1935), 18 (S W G)

Burns The Dr E C Davidson treatment of burns with compresses of 5% tannic acid is discussed Burns are classified as (1) 1st and 2nd degree involving only the epidermis, (2) 3rd degree penetrating only to the upper layer of the corium, (3) 4th degree involving the subcutaneous tissues and (4) 5th and 6th degrees penetrating to the muscle and bone First degree burns such as a mild sunburn usually involve the upper layer of the epidermis in which the scales fall off in a short time, 2nd degree burns are generally characterized by the formation of blisters, 3rd degree burns are the most painful since they leave the nerve filaments bare and exposed Local treatment provides (1) relief by exclusion of air and the use of a local anesthetic and (2) prevention of infection in which tannic and picric acids are of great help Minor burns are treated by ointments, salves and oils because of their occlusive nature, for more severe burns liquids and powders are used Other medicaments are olive and cod liver oils, vaseline, lead carbonate, boric acid, sulphonated bitumen, bismuth subnitrate and subgallate, thymol iodide, iodoform, sodium bicarbonate, resorcinol, zinc oxide, acetanilid, paraffin, potassium permanganate, ferric chloride, aluminum subacetate, lead subacetate, alum and calamine —ANON *Drug and Cosmetic Ind*, 36 (1935), 271-272, 276, 284 (H M B)

Cevitamic Acid (Ascorbic Acid)—Use of, in the Treatment of Infantile Scurvy Three cases of infantile scurvy were treated with cevitamic acid One patient, receiving one 10 mg tablet orally three times daily, was cured and discharged from the hospital one month from the beginning of treatment The other two patients were given 20 mg of cevitamic acid orally each day for 4 days, then 40 mg daily for 10 days Disappearance of the typical scorbutic symptoms was prompt in all cases In the latter two cases the cevitamic acid content of the blood serum before and after treatment was determined Before treatment, the serum contained 0.97 mg and 1.02 mg per 100 cc in the two cases In the one case, after 6 days of treatment, the serum cevitamic acid increased to 2.01 mg, and after 14 days it was found to be 1.97 mg The serum content in the second case increased from 1.02 mg up to 2.08 mg per 100 cc after 6 days' treatment the value being 2.06 mg on the 14th day —A F ABT and I M EPSTEIN *J Am Med Assoc*, 104 (1935), 634 (M R T)

Colds—Prescriptions for The author describes the "common cold" giving reasons for infection by the disease and suggestions for methods of protection and treatment Seven prescriptions are given which according to the author are beneficial in the treatment of colds —J W PECK *Chem and Drugg* 122 (1935), 44 (T G W)

Dextrose—Therapeutic Use of Dextrose is readily utilized by all body cells. It can be administered orally, rectally and by injection in large quantities without harm. In child therapy it is used in 5 to 10% solution. For rectal alimentation a 15% solution is used and by this avenue 200 to 300 Gm of dextrose can be supplied in twenty four hours. For a single enema, 250 to 350 Gm of an isotonic, 6% solution can be given. Dextrose is used in the treatment of diseases of the liver, being given simultaneously with insulin. It is also being employed parenterally in place of sodium chloride after operations. For this purpose a 6% solution of dextrose is used. In certain edemas, especially those of cerebral pressure, apoplexy and the like, the intravenous infusion of 50 to 100 cc of a 50% solution frequently brings about decided improvement. Intravenous injections of dextrose are used successfully in the treatment of acute nephritis, pulmonary edema, myocarditis, varicose veins and muscle rheumatism. Dextropur is recommended for use in place of ordinary dextrose because of its cheapness and purity. Since these dextrose solutions must be sterile, it is recommended that dextropur be dissolved in a 0.08% aqueous solution of Nipagin Nipazol consisting of 65 parts of Nipagin and 65 parts of Nipazol. Nipagin Nipazol has antiseptic but not germicidal action. Although investigations carried out by the author show that only harmless organisms are present in solutions prepared as recommended, in order to conform to the pharmacopoeial requirement, these solutions must be absolutely sterile. Heating in an autoclave at 120° C would insure absolute sterility, but this degree of heat would decompose many chemicals, therefore, bacterial filtration is recommended as a procedure for obtaining absolutely bacteria-free solutions.—H ESCHENDRENNER *Pharm Ztg*, 80 (1935), 70 (G E C)

Dioxyanthranol 1, 8, a Substitute for Chrysarobin Dioxyanthranol 1, 8 differs in its structural formula from chrysarobin by the lack of the methyl group. With physical and chemical properties similar to chrysarobin, it can replace the latter in practically all pharmaceutical combinations. Concentrations employed range from 0.1 to 5 per cent, but the safe effective range is stated to be between 0.1 to 1.5 per cent. Concentrations above 2 per cent produce a dermatitis. In addition to a review of the literature, the results of the use of dioxyanthranol in the treatment of over 100 cases of dermatoses, notably psoriasis, are presented. Because of the favorable results obtained, both as to effectiveness and freedom from undesirable reactions, the authors conclude that dioxyanthranol 1, 8 is an effective drug and a desirable substitute for chrysarobin in conditions in which chrysarobin has heretofore held the field.—H BEERMAN, *et al* *J Am Med Assoc*, 104 (1935), 26 (M R T)

Estrogenic Preparations—Relief of Menopause Symptoms by A general discussion of effectiveness, dosage, duration of treatment, the relative values of various products, contraindications, etc., as regards available preparations containing one or more of the hormones elaborated by the ovary and the anterior lobe of the pituitary, in relation to their use in the treatment of menopausal symptoms.—E L SERVINGHAUS *J Am Med Assoc*, 104 (1935), 624 (M R T)

Ferric Chloride—Use of, in Poison Oak Dermatitis Tincture of ferric chloride or a solution of 5 per cent ferric chloride in dilute alcohol is stated to be a specific in the prevention and treatment of poisoning from poison oak. For prevention, apply to the exposed parts of the body. For treatment, apply as early as possible. Reference is also made to a treatment by means of a solution of hyposulphite of soda.—*Calif and Western Med*, 42 (1935), 39 (B S R)

Fever Sores—Remedies for Fever, or cold sores, are discussed and the following recipes offered. **Colorless Lipstick Types**—(1) White beeswax 31%, cocoa butter 19%, lanolin 5%, menthol, 0.5%, thymol 0.1%, camphor 3%, petrolatum, soft, white, short fibre 41.4%. (2) White beeswax 30%, paraffin 2%, petrolatum, soft white 49.8%, cocoa butter 8%, benzocaine 1%, lanolin 5%, camphor 2%, phenol 0.2%, chloroform 2%. Dissolve the benzocaine in the chloroform, melt the other ingredients and add the chloroformic solution. **Ointments**—(1) Tr benzoin 20%, balsam Peru 10%, cold cream 70%. Heat the cream and stir in the other ingredients until smooth and uniform. (2) Benzocaine 3%, Co tr benzoin 20%, balsam Peru 10%, cold cream 61%, chloroform 6%. Dissolve the benzocaine in the chloroform, heat the cream and mix in the other ingredients adding the benzocaine soln last.—ANON *Drug and Cosmetic Ind*, 36 (1935), 285, 287 (H M B)

Gonorrhea in Children—Recent Progress in the Treatment of Theelin, intramuscularly

is suggested for the treatment of gonorrhea in children. Subsequent changes (hypertrophy) of the vaginal mucosa renders the mucosa unfit as a habitat for the Neisserian organism. No failures by this method have thus far been reported.—W A N DORLAND *Clin Med Surg*, 42 (1935), 23 (B S R)

Hydrochloric Acid—Use of, in Tonsillitis In acute tonsillitis, intravenous injections of hydrochloric acid act like a specific. Two injections on two succeeding days (no more) of 10 cc of a 1 1500 or 1 1000 solution of the acid are given. Sometimes one injection is enough.—W J HOWELL *Med World* Jan 1935, through *Clin Med Surg*, 42 (1935), 146 (B S R)

Methylene Blue—Intravenous Use of, in the Treatment of Cyanide and Carbon Monoxide Poisoning A new procedure for the treatment of cyanide and carbon monoxide poisoning with methylenic blue is given.—J C GEIGER and J P GRAY *Clin Med Surg*, 42 (1935), 96 (B S R)

Nirvanol—Treatment of Chorea with A review of the reported evidence of the value of nirvanol in the peroral treatment of chorea.—L E BENDER and G E PRATT *Med Rec* 141 (Mar 1935), 300 (B S R)

Paraldehyde—Advantages of, as Basic Amnesic Agent in Obstetrics In 100 consecutive cases paraldehyde was used as the basic amnesic agent in synergistic combination with sodium amytal, nitrous oxide and ether being depended upon for analgesia and anesthesia during the latter part of labor and at delivery. Six to 8 drachms of paraldehyde, mixed with an equal volume of olive oil, was administered by rectal tube one half to one hour after the amytal had been given. Because a satisfactory analgesia and amnesia was obtained which apparently did not interfere with physiological labor it was concluded that paraldehyde as a basic amnesic agent in combination with sodium amytal or pentobarbital approaches the ideal in satisfying the fundamental requirements pertaining to labor. The authors state further that there are no contraindications to its use in home confinements.—E D COLVIN and R A BARTHOLOMEW *J Am Med Assoc* 104 (1935), 362 (M R T)

Pentonitis—Prophylactic for Antimotic fluid is recommended for the prevention of peritonitis following severe abdominal operations. References are given.—*Clin Med Surg*, 42 (1935), 29 (B S R)

Phenylmercuric Nitrate—Treatment of Chronic Vaginitis with A report of a case which had resisted all efforts at treatment for 5½ years. An apparently permanent cure was promptly brought about by the use of douches of phenylmercuric nitrate in glycerin 1 1500 diluted down to 1 20,000.—F W HITCHINGS *J Am Med Assoc*, 104 (1935), 212 (M R T)

Psorimangan—Value of, in Psoriasis and Ichthyosis Case reports of the successful treatment of psoriasis and ichthyosis by the injection of Psorimangan, a colloidal form of manganese.—C R PERDUE *Clin Med Surg* 42 (1935), 143 (B S R)

Verodigin—Value of, in Cardiovascular Disease A clinical study of the therapeutic efficiency of Verodigin, the gitalen glucosides of digitalis. References are given.—W T SROUD *et al* *Clin Med Surg*, 42 (1935), 100 (B S R)

Vinethene A review with references of the chemical and experimental investigation of vinethene (vinyl ether). Vinethene is vinyl ether with the addition of 3.5% of absolute alcohol and 0.01% of a nonvolatile oxidation inhibitor. The properties of vinethene are as follows: Clear, colorless liquid, except for a purple fluorescence. Sp Gr of 0.77. B P of 28.3° C, garlic odor, highly inflammable and explosive and heavier than air. It should be preserved in well stoppered containers in a cool place remote from light, fire and acid fumes. Should not be used more than twelve hours after the bottle has been opened. The writer states that vinethene possesses the best characteristics of ethylene chloride and ether without their disadvantages, being extremely rapid in action with quiet induction, not unpleasant to inhale, non irritating to the respiratory passages with a theoretically wide margin of safety, a rapid recovery free from unpleasant after effects, little effect on the respiration and practically no effect on the heart and blood pressure. Complete muscular relaxation has not always been obtained and liver necrosis has been reported in some cases. A brief description is given of the methods of administration with precautions and recommendations.—F E SHIPWAY *Lancet* 1 (1935), 82 (B S R)

NEW REMEDIES

SYNTHETICS

Eunarcon (J D Riedel & Co. Hagen A G, Berlin) is a 10 per cent stabilized aqueous solution of the sodium salt of isopropyl β bromallyl *N* methylmethylonylurea suitable for intravenous injection. It is used as a narcotic in simple surgeries and in gynecology similar to ethyl chloride anesthesia, or as a full narcotic in short operations.—*Pharm. Zentralh.*, 76 (1935), 72 (E V S)

Haemodan (Syntetica, Grinsted, Denmark) is an intermediate product in the preparation of adrenalin, and is used as a hemostatic in the 'Strylin preparations'—*Pharm. Weekblad*, 72 (1935), 226 (E H W)

Rossium Diphenylmethylpyrazolonyl. It is used in cases of abrupt withdrawal of morphine from morphine addicts. The dosage is 0.5 Gm. per every 10 lbs. body weight per day for five days. It is supplied in bottles of 25, 50 and 100 capsules.—*Drug Circ.*, 79 (Jan. 1935), 31 (T G W)

Zephirol—New Disinfecting Agent. Zephirol is a high molecular weight alkyl di-methyl benzyl ammonium chloride. It yields a clear yellowish white, slightly alkaline solution which froths strongly on shaking, and which possesses a weak agreeable odor. It kills coli, staphylococcus, streptococcus, pneumococcus, anthrax, typhoid, paratyphoid, dysentery, diphtheria and gonococcus organisms within 2½ minutes in a one per cent solution even in the presence of 10 per cent serum albumin. The Rideal-Walker test shows that Zephirol is 10 times stronger than cresol soap solution. Tests showed that 15 cc. bouillon cultures of various germs such as coli, streptococcus and anthrax were rendered sterile within two minutes by one drop of a one per cent solution of Zephirol. It was also shown that the solution can be used successfully in disinfecting hands, rubber gloves and bacterial filtration apparatus. The bacterial filtration apparatus may be kept always sterile and ready for instant use by being stored in a one per cent Zephirol solution, however, the membranous filters become brittle and unreliable on being kept in the solution twelve hours or longer. To avoid this, the filters should be placed in Zephirol solution for one hour, rinsed with sterile water and then kept in Nipagen-Nipasol solution. Sterile solutions of drugs for injection may be prepared by solution of the desired substance in a 0.08 per cent solution of Nipagen-Nipasol and subsequent filtration through apparatus made and kept sterile as described.—H. ESCHENBRENNER. *Pharm. Ztg.*, 80 (1935), 94 (G E C)

SPECIALTIES

A-B-D Capsules (Abbott Laboratories, North Chicago, Ill.) Capsules containing the equivalent of at least three teaspoonsful of cod liver oil in vitamins A and D, two cakes of moist compressed yeast in vitamin B₁ content and one-half cake of moist compressed yeast vitamin B₂ (G) content. They are used for the treatment of disorders due to a lack of vitamins A, B₁, B₂ (G) and D. They are supplied in boxes of 25 and 100 capsules.—*Drug Circ.*, 79 (Mar. 1935), 33 (T G W)

Acetylcarbromal (Syntetica, Grinsted, Denmark) is acetylcarbromal, which is also found on the market under the trade name of "Abasine"—*Pharm. Weekblad*, 72 (1935), 225 (E H W)

Aconite-dispert (Dispert Ltd., The Hague) is an aconite extract prepared by the dispert-method of Krause. In the dispert-method the liquid extract obtained from the plant parts is finely subdivided. So finely, in fact, that one liter is sprayed over a surface 300 M. square. It dries during the spraying, the speed of the droplets of mist being 140 M. per second. Aconite-dispert so obtained from aconite root is made up into tablets of two strengths, standardized as equivalent to 0.05 mg. of aconite per tablet and 0.2 mg. of aconite per tablet. The tablets contain besides aconitine the other alkaloids and therapeutic constituents of aconite and are employed in neuralgia, migraine, etc.—*Pharm. Weekblad*, 72 (1935), 70 (E H W)

Aderol (Kynazon-Werk, Frankfurt a. M.) is an external alcoholic preparation containing *d*-bornyl acetate (1 per cent), an isothiocyanic acid ester (0.5 per cent), camphor (5 per cent) and ethereal oil (17 per cent). It is used in the treatment of whooping cough, bronchitis and pneumonias of infants and older children.—*Pharm. Zentralh.*, 76 (1935), 104 (E V S)

Adiposettes are coated tablets supplied in packages of 250 by Rudolf Reiss, Berlin, Germany. They are used as fat reducing agents and consist of *Fucus vesiculosus*, frangula, leicthm dihydroxyphthalophenon ester and tritetrachorylhistrioxproparyl ester — *Pharm Ztg*, 80 (1935) 109 (G E C)

Adormine-tablets (Apogepha, Dresden) contain 0.5 Gm of bromdiethylacetylcarbamide — *Pharm Weekblad*, 72 (1935) 70 (E H W)

Agrypnal Ampuls (Medica, Prague) of 20 or 30 per cent phenylethylbarbituric acid, acetamide, propionamide, heptane and distilled water are prepared by Eggochemia, Vienna — *Drug and Cosmetic Ind*, 36 (1935), 93 (H M B)

Albicol is composed of purified colloidal aluminum silicate, hetanaphthol henzoate, bismuth subsalicylate and aromatics. It is indicated in cases of gastric ulcer, gastric hyperacidity and ulcerative colitis. It is supplied in 3-ounce canisters — *Drug Circ* 79 (Feb 1935) 27 (T G W)

Aletemilch (Alete Pharm Producte G m b H, Munich) is dried whole milk previously acidified with lemon juice. It is used as a nourishment for infants and small children — *Pharm Zentralh*, 76 (1935) 104 (E V S)

Allpropan-tablets (Apogepha, Dresden) contain 0.16 Gm of diallyldipropylbarbituric acid with bromdiethylacetamide — *Pharm Weekblad* 72 (1935) 70 (E H W)

Alloton (J D Riedel E de Haen A G, Berlin) is a chemical combination of garlic oil (12 per cent) and dioxycholic acid, in addition each coated pill contains the active constituents of 1 Gm of fresh garlic. Its use is indicated in digestive disorders, worms, climacteric changes and arteriosclerosis — *Pharm Zentralh*, 76 (1935), 71 (E V S)

Allypropynal ('Synthetic,' Grindstedvaerket, Denmark) is allylisopropylbarbituric acid. This is employed in preparing 'Givofen' and 'Givonal' (see below). It is likewise a constituent of Allonal — *Pharm Weekblad* 72 (1935), 177 (E H W)

Aluminium-acetate-dispert (Dispert Ltd, The Hague) is aluminium acetate in powdered form prepared by the dispert method, which retains its solubility and may be employed for the preparation of aluminium acetate solutions. It is supplied in 5 Gm packages or may be obtained in bulk — *Pharm Weekblad*, 72 (1935) 70 (E H W)

Androstina (Ciha) is a biologically titrated extract from testes. It is marketed in ampuls, six to the box, of which three contain water as the solvent and three contain fat as the solvent for the extract. The latter must be heated to body temperature before using. Androstina tablets are red in color, each containing the active constituent of 8 Gm of fresh testes — *Pharm Weekblad*, 72 (1935), 225 (E H W)

Anginal Tablets (Medica, Prague) contain pyrocyanic-protein sec, menthol and oil of thyme. They are marketed in packages of 20 tablets — *Drug and Cosmetic Ind*, 36 (1935), 93 (H M B)

Aplona (Dispert Ltd, The Hague) is a light brown powder which clots easily. It is prepared from fresh apples without the addition of other material by the dispert method of Krause. It is used in the apple diet for diarrhoea — *Pharm Weekblad*, 72 (1935) 70 (E H W)

Arsenetten (Zima) are tablets containing arsenious acid, yeast extract and yeast vitamins. The tablets weigh 0.2 Gm and contain 0.001 Gm of arsenious acid. Dose, 1-3 tablets per day — *Pharm Weekblad* 72 (1935), 178 (E H W)

Belladonna-dispert (Dispert Ltd, The Hague) is prepared by the dispert method of Krause. It is a belladonna extract free from inert substances and containing only the active constituents of belladonna, particularly 1 hyoscyamine. Belladonna dispert is given in powdered form in doses of 10-30 mg and is biologically standardized to an atropine content of 1.5%. Belladonna dispert-liquidum is a clear liquid of which the dose is 10-15 drops. Belladonna dispert tablets of which one tablet contains 0.25 mg of atropine, are used in doses of 1-2 tablets. The suppositories contain 0.3 mg of atropine per suppository — *Pharm Weekblad*, 72 (1935), 70 (E H W)

Bellergal (Sandoz Chemical Factory) contain 0.0001 Gm hellafoline 0.0003 Gm gyncergen and 0.02 Gm phenylethylbarbituric acid. They are used in vasoneurosis, Grave's disease, migraine, menstrual disturbances, etc. Dose 4-6 tablets per day — *Pharm Weekblad*, 72 (1935) 225 (E H W)

Bio-Talc (Dr Boucard, Paris) is a talcum powder containing milk ferments — *Pharm Weekblad* 72 (1935) 71 (E H W)

Blimal (Laboratoires de Pharmacologie médicale, Paris) is a solution of hexamethylenediamine iodomethylate, dimethylenediamine salicylate and papaverine hydrochloride offered in ampuls for the treatment of rheumatic affections—*Pharm Weekblad*, 72 (1935), 71 (E H W)

Broeanal (Curta and Co, G m b H, Berlin-Butz) are tablets containing, in each, 0.025 Gm of phenylethylbarbituric acid, 0.4 Gm of bromcalcium diethanolamine (equivalent to 0.15 Gm of bromine and 0.037 Gm of calcium) and 0.015 Gm of caffeine. They are indicated in genuine and traumatic epilepsy, mental disturbances of convalescence, depression and climacteric disturbances—*Pharm Zentralh*, 76 (1935), 71 (E V S)

Calcitrine Calcitrine is indicated in coughs due to colds, tracheitis and acute inflammation of the respiratory tract. Each fluidounce represents calcium iodide, 7 grs (equivalent to iodine, 6 grs), ephedrine hydrochloride, $\frac{3}{8}$ gr, nembital, $\frac{3}{8}$ gr, syrup wild cherry, tolu, aromatics, q s. It is supplied in pint and gallon bottles—*Drug Circ*, 79 (Feb 1935), 26 (T G W)

Calciphos A slightly grayish white powder containing about 19% calcium, 15% phosphorus and 2% iron as salts of inositol hexaphosphate, occurring naturally in Indian corn. It is used for calcium medication in diseases and conditions resulting from a mineral deficiency, such as malnutrition, rickets, dental caries, during pregnancy and lactation, and in allergic conditions. It is packaged as powder in 3 ounce boxes and as 6 gr tablets—*Drug Circ*, 79 (Jan 1935), 30 (T G W)

Calmuran (Dr Hans Truttwin, Dresden) is an ointment containing brominated uranium oxide (9% uranium, 7% bromine). The ointment has the consistency of Unguentum Leniens and is employed to relieve itching—*Pharm Weekblad*, 72 (1935), 225 (E H W)

Camrol is composed of iodoform, iodides, menthol, camphor and oil of sweet almonds. Intramuscularly it has been found very beneficial in the treatment of the early stages of pulmonary tuberculosis, tuberculosis of the bone, sinus infections, influenza, pneumonia and the common bronchial affections—*A E OLPP Med Rec*, 141 (Feb 1935), 157 (B S R)

Cantan (Bayer, I G Farbenindustrie A G, Leverkusen a Rh) is a tablet containing 0.025 Gm of l ascorbic acid the C vitamin Bayer. It is indicated in scurvy and all the early stages of pronounced hypovitamin conditions, in hemophilia and to assist in the treatment of infectious diseases—*Pharm Zentralh*, 76 (1935) 72 (E V S)

Cebione (Merck & Co, Rahway, N J) Cebione is cevitic acid, a pure vitamin C, which was formerly called ascorbic acid. A white or slightly yellowish white odorless crystalline powder, used in the treatment of diseases where there is a deficiency of vitamin C. It is supplied in tubes of 10 and 100, 0.01-Gm and 0.05 Gm tablets for oral use and in ampuls containing 0.1 Gm—*Drug Circ*, 79 (Mar 1935), 32 (T G W)

Citopogeen (Royal Pharm Factory Brocades & Stheeman and Pharmica, Netherlands) is a disinfectant especially designed for veterinary purposes. It serves for the extermination of vermin, for the sterilization of instruments and as an irrigating liquid (1-3%). It is not poisonous, only slightly stimulant and according to the researches of Prof de Bieck is more powerful than lysol, lysoform, carbol and therapogen—*Pharm Weekblad*, 72 (1935), 225 (E H W)

Coderit Tablets (Sanabo chinoin G m b H, Vienna) contain 0.02 Gm codeine hydrochloride, 0.02 Gm Ephert (chloride of synthetic racemic ephedrine), 0.0005 Gm total alkaloids of ipecac. They are marketed in packages of 10 tablets—*Drug and Cosmetic Ind*, 36 (1935), 93 (H M B)

Colchicum-dispert (Dispert Ltd, The Hague) is an extract obtained from colchicum seeds by the dispert-method, the colchicine content being standardized. The extract is also standardized biologically. It is put up in capsules, the dose in chronic cases being 1-3 per day, and in acute rheumatic attacks, one capsule 6-7 times per day—*Pharm Weekblad*, 72 (1935), 71 (E H W)

Collumol (Dr Blajet's Chemical Factory) is a colloidal peptic aluminium hydroxide. It is employed in various stomach affections and as an antidiyspeptic in hyperacidity, in abnormal fermentation, etc. Collumol, under the influence of the acid of the gastric juice, settles as a gelatinous film on the stomach walls. It is found on the market in powdered form—*Pharm Weekblad*, 72 (1935), 225 (E H W)

Comallysatum (Bürger, Zima) is a product obtained from *Allium ursinum* by dialysis. It occurs on the market in liquid form and in ampuls. It contains the same therapeutically active

constituents as the wild growing *Alum ursinum* which has bactericidal properties, and is recommended in intestinal dyspepsia, loss of appetite and amoebic dysentery. Dose, $\frac{1}{2}$ teaspoonful 2-3 times a day or two ampuls 3-4 times a day — *Pharm Weekblad*, 72 (1935), 178 (E H W)

Curcumen (Temmler Works Berlin) is distributed in capsules and ampuls. The capsules contain 0.1 Gm of curcumine sodium and 0.1 Gm calcium chlorate. The ampuls contain 5 cc of a 5% solution of curcumine sodium. They are employed in liver and gall bladder diseases — *Pharm Weekblad*, 72 (1935), 71 (E H W)

Corvis (M. J. Lewenstein Amsterdam) is pentamethylenetetrazol, $C_6H_{10}N_4$, which is the same compound found on the market under the names of Cardiazol and of Pentazol. It is also employed as a powerful analeptic for the heart and respiratory center. Administration per os results in an action of greater duration than subcutaneous, intramuscular or intravenous injection. It comes on the market as a powder, in solution in tablets of 0.1 Gm and in ampuls of 0.1 Gm per cc — *Pharm Weekblad*, 72 (1935), 225 (E H W)

Cynhepatil (Lab. Benderitter) has the following composition: Extract of artichoke leaves 100 mg, stabilized liver powder, 100 mg, purified meat peptone, 100 mg, talc, acacia, corn starch, gluten, gum lac, black glycine Klotz, naphthol yellow Blayn in tablet form. Marketed in bottles of 60 tablets — *Drug and Cosmetic Ind.* 36 (1935), 93 (H M B)

Cystoblettes. This preparation manufactured by H. L. Ritter and Co. Berlin, Germany, contains 40 dragees to the package. It consists of Extract of Buchu, Salol, Benzoic Acid, Extract of Uva Ursi, Hexamethylenetetramine and Monobromated Camphor. It is recommended by the manufacturer for acute and chronic gonorrhea and their complications, simple urethritis, cystitis, pyelitis and pyelonephritis — *Pharm Ztg*, 80 (1935), 72 (G E C)

Danamine ('Syntetic', Grindstedvaerket, Denmark) is 3-pyridine carbonic acid diethyl amide, a crystalline material melting at 26-28° and easily soluble in water. It is identical with Coramine and is likewise used as a cardiac tonic. It replaces camphor for injection and is used in carbon monoxide poisoning. It is employed in 25% solution with the addition of a little acid for injection — *Pharm Weekblad*, 72 (1935), 178 (E H W)

Danarsine ('Syntetic', Grindstedvaerket, Denmark) is the calcium salt of allylarsenous acid $C_3H_5AsO_2Ca \cdot H_2O$. It agrees in composition with 'Arsyleen'. Its content of water free salt is 90.4%. Danarsine is a whitish powder with a light yellow tint. The name may easily be confused with Danamine (from the same factory) especially in prescriptions which are not legibly written — *Pharm Weekblad*, 72 (1935), 178 (E H W)

Daucaysatum (Burger Zyma) is a dialytic prepared from *Daucus Carota*, the volatile oils of which possess anthelmintic properties especially for thread worms and round worms — *Pharm Weekblad*, 72 (1935), 178 (E H W)

Deriphyllin Ampuls (Chemisch Pharmazeutische Aktiengesellschaft, Bad Homburg, Germany). This preparation is used for the intravenous and intramuscular injection of theophylline oxyamine. Each cc of solution corresponds to 0.412 Gm of deriphyllin. It is supplied in boxes of 6, 25 and 100 ampuls — *Pharm Ztg*, 80 (1935), 109 (G E C)

Deriphyllin Suppositories (Chemisch-Pharmazeutische Aktiengesellschaft, Bad Homburg, Germany). Each suppository contains 0.618 Gm of deriphyllin. 1 to 4 suppositories may be taken daily. The preparation is especially useful in angina and cardiac dyspnea. It is supplied in packages of 6, 25 and 100 — *Pharm Ztg*, 80 (1935), 109 (G E C)

Dermarodyl (Dr. Hugo Rosenberg, Freiburg) has as its active constituent a sulphocyanide derivative of acetyltrimethylcolamine dissolved in a water free solvent which is readily absorbed through the skin. It combines the blood pressure lowering properties of acetylcholine with those of the sulphocyanide. Action follows rather rapidly upon absorption through the skin — *Pharm Weekblad*, 72 (1935), 225 (E H W)

Diacedan is prepared in a Danish factory. This name is given to diacetyldioxyphenylisatine which is also found on the market under the name of 'Isaceen' and which is official in the Danish pharmacopoeia as 'Acetphenolisatinum' — *Pharm Weekblad*, 72 (1935), 226 (E H W)

Digitalis-dispert (Dispert Ltd., The Hague) is obtained by the dispert method of Krause and biologically assayed by the Houghton-Straub method. It is a cold water extract of digitalis leaf prepared in the customary way, sprayed and dried. It occurs on the market in powdered form in tablets of 150 F.D. (frog units), as Digitalis dispert-liquidum of which 1 cc is equivalent to 200 F.D. and in suppositories of 300 F.D. — *Pharm Weekblad*, 72 (1935), 71 (E H W)

Distol (Chimiofabriek at Budapest) is a medication used for distomatose in cattle. According to Gelie's Codex it contains the active constituents of male fern and is marketed in capsules—*Pharm Weekblad*, 72 (1935) 226 (E H W)

Diuretysatum (Burger, Zyma) is a dialysate prepared from squill, juniper berries and birch leaves. It stimulates kidney function and promotes diuresis. In addition it possesses the properties of a cardiac tonic. Dose: one teaspoonful three times daily—*Pharm Weekblad*, 72 (1935) 178 (E H W)

Dormalets (Dr R. Weiss, Berlin) are tablets containing 0.32 Gm. of calcium lactobromide, 0.05 Gm. pyranidon and 0.08 Gm. sodium phenylethylbarbiturate. They are employed in insomnia—*Pharm Weekblad*, 72 (1935), 71 (E H W)

Endomin (Reed and Carnrick, Jersey City, N. J.) is the name of a tablet containing iron, 80 mg., copper, 0.6 mg., manganese 0.4 mg., zinc, 0.3 mg., nickel, 0.03 mg., cobalt, 0.03 mg., and sodium germanate, 0.05 mg., in lipid soluble form. Endomin is indicated in the treatment of anemias. It is supplied in bottles of 100, 500 and 1000 tablets—*Drug Circ*, 79 (Mar 1935), 32 (T G W)

Endothyron is a product recommended for conditions due to hypothyroidism, obesity, dermatoses and ovarian dystrophies. It is supplied in bottles of fifty $\frac{1}{2}$ gr. tablets and boxes of five 1 cc. ampuls. The composition of the product is thyroid, U S P triple strength, gr $\frac{1}{2}$, lactose and starch, q s ad gr 4. It is contraindicated in hyperthyroidism, cardiac instability and extreme nervousness—*Drug Circ*, 79 (Jan 1935), 31 (T H W)

Endothyron (Endocrines, Ltd., London) is a standardized thyroid containing double the prescribed quantity of iodine and is used in hypothyroidism, myxedema, etc. It is marketed in bottles of 50 or 100 $\frac{1}{2}$ grain tablets—*Drug and Cosmetic Ind*, 36 (1935), 93 (H M B)

Ephepurine (Amsterdam Quinine Works) is a combination of acetylsalicylic acid and ephedrine appearing on the market in tablets of 0.5 Gm. The proportion is not stated—*Pharm Weekblad*, 72 (1935), 71 (E H W)

Epitheel-Dragees (Burger) are prepared from Glandula Parathyroidea Siccata. Each tablet contains 8 mg. of the dried powder. They are recommended to maintain a normal calcium balance. They are used to raise the calcium content in persons with calcium deficiency, by oral administration. Dose, one tablet three times daily—*Pharm Weekblad*, 72 (1935), 178 (E H W)

Eusod (H. Schering-Kahlbaum A. G., Berlin) is a heartburn remedy containing a synthetic aluminum sodium silicate and pure magnesium oxide in which the action of the silicate component is gradually liberated but hastened by the magnesium—*Pharm Zentralh*, 76 (1935), 105 (E V S)

Feosol S-K-F (Smith, Kline and French Laboratories, Philadelphia Pa.) Tablets containing 3 grains of exsiccated ferrous sulphate, U S P with a special vehicle and coating to prevent oxidation and promote disintegration. They are indicated in the treatment of secondary anemia, idiopathic hypochromic anemia, chlorosis, hypochromic anemia of pregnancy, the anemia following menorrhagia, and in other microcytic anemias accompanied by a low color index. They are supplied in packages of 100, 1000 and 5000 tablets—*Drug Circ*, 79 (Mar 1935) 33 (T G W)

Frangula-dispert (Dispert Ltd. The Hague) is an extract prepared by the dispert-method from Frangula bark and made into tablets, each with a content of 25 mg. of emodin. Dose, 1-3 tablets—*Pharm Weekblad*, 72 (1935) 72 (E H W)

Givofen ("Syntetic," Grindstedvaerket, Denmark) is a solution containing 100 Gm. allyl propynal and 100 Gm. diethylbarbituric acid in 100 cc.—*Pharm Weekblad*, 72 (1935) 178 (E H W)

Givonal ("Syntetic," Grindstedvaerket, Denmark) is a mixture of 100 parts of amidopyrine and 60 parts of allylpropynal (allylisopropylbarbituric acid). It comes on the market as tablets, each containing 0.1 Gm. of amidopyrine and 0.06 Gm. of allylpropynal—*Pharm Weekblad*, 72 (1935) 178 (E H W)

Gynergeen, ergotamine tartrate, is a tartrate of the alkaloid obtained from ergot by the Stoll method. It has recently been employed not only in obstetrics but also in the treatment of Graves' disease—*Pharm Weekblad*, 72 (1935) 72 (E H W)

Horosteon (Dispert Ltd, The Hague) is an extract of bone marrow prepared by the method of Dr W Hoffmeister. It is obtainable in ampuls containing 1 cc of the colorless liquid, which serves to hasten delayed calcification in bone breaks — *Pharm Weekblad* 72 (1935), 72

(E H W)

Iod-Tetragnost-Powder (E Merck, Darmstadt) is the sodium derivative of tetraiodo phenolphthalein — *Drug and Cosmetic Ind*, 36 (1935), 93

(H M B)

Kessoval (Schering-Kahlbaum) is a preparation made from valerian root by a new method. According to the manufacturer it contains all the active constituents of the root. It comes on the market in the form of capsules — *Pharm Weekblad* 72 (1935), 226

(E H W)

Laxatives A general discussion introducing new products — *ANON Drug and Cosmetic Ind*, 36 (1935), 31, 34

(H M B)

Leukichthol A light ichthyol preparation (Leukichtbol) with a total sulphur content superior to that of ichthyol, i.e., 12-13% as compared with 10-11%, is described. Not only has the preparation increased reducing power but a 2-5% concentration acts as effectively as a 10-20% preparation of ichthyol. Smaller doses are sufficient when intended for the face and other delicate skin surfaces, e.g., scrotum. Since this preparation is completely colorless it is very useful for cosmetic ointments, pastes, rinses and varnishes. For the same reason, this salve may be applied for day use on the uncovered parts of the body, face and hands. A very active and practically unnoticeable preparation is made with gelanthus using 2% of the ointment. Up to date Unna has treated 67 cases of dermatoses with good results in dermatitis, urticarial and congestive dermatoses, keratoid eczema, and especially allergic dermatoses due to light, leather and fur — *P. UNNA, Jr Dermatol Wochschr*, 100 (1935), 54, through *Squibb Abstract Bull*, 8 (1935), A 329

Lidrosan (Laboratory of Lansbery & Son, Rotterdam) is a liquid extract of *Drosera rotundifolia*, *Thymus vulgaris* and *Pinguicula vulgaris* and is used in the treatment of whooping cough. Dose, 3-15 drops three times a day — *Pharm Weekblad*, 72 (1935), 72

(E H W)

Mebaral N-Methylethylphenylmalonylurea. A white, odorless and tasteless powder used as a sedative and antiepileptic. It is supplied in bottles of 25 and 100, 3-gr tablets and bottles of 100, 1/2 gr tablets — *Drug Circ*, 79 (Feb 1935), 27

(T G W)

Mistol (Deutsche Gesellschaft für Pharmazie u Kosmetik m b H, Berlin) is an alcoholic inhalant containing camphor (12.4 per cent), menthol ester (16.8 per cent) and oil of eucalyptus (15.5 per cent) which is used as an inhalant for colds and catarrh — *Pharm Zentralh*, 76 (1935), 72

(E V S)

Moru-Quin A solution of the sodium salts of the fatty acids of cod liver oil, containing 5% of sodium morrbuate, 2% of alkaloidal quinine, and 2% of benzyl alcohol. The preparation is injected for the treatment of varicose veins. It is supplied in 5-cc and 25-cc ampuls — *Drug Circ* 79 (Jan 1935), 30

(T G W)

Naftalan is claimed to be a mild non irritating crude naphthal found in the Caucasus, and to show an inhibiting effect on inflammations of various types, rapid resorption and in general therapeutic properties intermediate between those of ichthyol and tar. It is indicated in dermatoses such as rosacea, pruritus, etc., and all forms and degrees of eczema. It may be combined with a suitable base and used in ointment or suppository form — *W. CASPER Dermatol Wochschr*, 99 (1934), 1615, through *Squibb Abstract Bull*, 8 (1935) A-301

(S W G)

Neo-Oleosol (I G Farben) is a painless injectable bismuth preparation. It is a 10% solution of dimethylendomethylene hexahydrobenzoic acid bismuth in olive oil. The salt contains 30% bismuth, the oil 3%. The bismuth may be determined by dissolving in benzene acidifying with hydrochloric acid and shaking out with dilute hydrochloric acid. Neo Oleosol is sold in ampuls of 2 cc exclusively for intramuscular injection. Dose (adults) one injection 2-3 times per week — *Pharm Weekblad* 72 (1935) 226

(E H W)

Neo-Psicobenzyl (Drs R & O Weil, Frankfurt) is a psicaine anaesthetic paraffin emulsion used in throat and mouth affections — *Pharm Weekblad* 72 (1935) 72

(E H W)

Nitrodan ('Syntetic,' Grindstedvaerket Denmark) is α dinitrophenol, a weight reducing drug which has recently appeared on the market under many fantastic names. Dose, 0.05 Gm. It is a light yellow powder melting at 111-112°, and may be titrated with bromthymol blue as an indicator — *Pharm Weekblad* 72 (1935), 179

(E H W)

Pancreas-dispert (Dispert Ltd The Hague) is prepared by the method of Krause from the pancreas of healthy slaughter house animals. It is also available in the form of an ointment

(Unguentum Pancreas dispers) or "Pyosalva" and a plaster (Emplastrum Pancreas dispers). Internally it is used as an aid to digestion. It is found on the market in tablets having a lipase value of 0.25 and as a powder having a lipase value of 0.35—*Pharm Weekblad*, 72 (1935), 72 (E H W)

Pentazol ("Syntetic," Grindstedvaerket, Denmark) is pentamethylenetetrazol, a compound resembling cardiazol, of which the identity and purity may be determined as provided in the Supplement of the 5th edition of the Dutch Pharmacopœia—*Pharm Weekblad*, 72 (1935), 179 (E H W)

Pertussine-drops (E. Taeschner, Potsdam) contain a perecolate of *Thymus vulgaris*, *Drosera rotundifolia* and other saponin and silicic acid containing plant parts with the addition of ephedrine hydrochloride—*Pharm Weekblad*, 72 (1935), 72 (E H W)

Phenylal (Apogeepla, Dresden) is phenylallylbarbituric acid—*Pharm Weekblad*, 72 (1935), 72 (E H W)

Phalonin (Chem. Fabrik Promonta G. m. b. H., Hamburg) are suppositories containing copper iodo-oxyquinoline sulphate, silver nitrate and irradiated cholesterol with local anesthetics. They are indicated for use in hemorrhoids, anal fissures, perianal eczema and other anal diseases—*Pharm Zentralh.*, 76 (1935), 72 (E V S)

Photodyn (Nordmarkwerke, G. m. b. H., Hamburg) consists of a 0.2 per cent solution of hematoporphyrin in ampuls of various sizes. The "drops" consist of 0.05 per cent hematoporphyrin in hydrochloric acid solution—*Drug and Cosmetic Ind.*, 36 (1935), 93 (H M B)

Pneumostagnine (Dr. G. Henning) is a sterile solution of quinine and camphor in ethyl chaulmoograte used in pneumonia, bronchitis, etc—*Pharm Weekblad*, 72 (1935), 72 (E H W)

Ponine (Laboratories de pharmacologie médicale, Paris) is a weight-reducing remedy distributed as cachets and granules. The composition unknown—*Pharm Weekblad*, 72 (1935), 72 (E H W)

Procythol forte Ampuls (Sanabo Chimoin G. m. b. H., Vienna) consist of liver extract for injection, each ampul is equivalent to 5 Kg. fresh liver. Packages of 5 ampuls from 2-20 cc—*Drug and Cosmetic Ind.*, 36 (1935), 93 (H M B)

Psorimangan "Weil" is an aqueous colloidal suspension of manganese dioxide, used in the treatment of psoriasis and furunculosis. It is supplied in 1- and 2-cc ampuls for intramuscular injections and 1- and 2-cc ampuls for intravenous injections—*Drug Circ.*, 79 (Jan 1935), 30 (T G W)

Pyosalva (Dispert Ltd., The Hague) is an ointment consisting of pancreatin (2%) in vaseline. The addition of this ferment to vaseline serves to hasten the disappearance of suppurating wounds and inflamed tissue thus often making incisions unnecessary—*Pharm Weekblad*, 72 (1935), 73 (E H W)

Quinine-Calcium-Sandoz (Sandoz Chemical Factory, Basel) is a combination containing in 10 cc of the solution, 0.6 Gm. quinine glueconate (corresponding to 0.37 Gm. of quinine base) and a 10% solution of Sandoz-calcium solution. It is found on the market in ampuls of 10, 5 and 2 cc. This medicament possesses the antixudative properties of calcium with its tonic effect upon heart and blood vessels combined with the anti-infective, antipyretic and sedative properties of the quinine. It is employed in croup, pneumonia, grippe, angina, etc—*Pharm Weekblad*, 72 (1935), 73 (E H W)

Rectidon is the sodium salt of secondary amyl-β-bromallylmalonylureide. It is marketed as a stabilized 10% aqueous solution and in suppositories. The formula is $C_{12}H_{19}O_3N_2BrNa$. It is used in surgery and gynecology in supporting inhalation narcosis at the start and also as a local and spinal anæsthetic. The dose of Rectidon is 8 cc. for men, 7 cc. for women and for ten-year-old children 4 cc. diminishing to 1 cc. for children of one year. Rectidon is employed in doses of 6-7 cc., 2-3 times daily in the treatment of the morphine habit by sleep of extended duration. Pharmacologically it is a homolog of "pernocton". The patient falls asleep within 15 minutes after (rectal) injection. Rectidon is found on the market in boxes containing one ampul of 10 cc., in 100-cc. bottles, in boxes of 3 suppositories of 0.4 Gm. and in boxes of 50 suppositories—*Pharm Weekblad*, 72 (1935), 226 (E H W)

Rsulform (Dr. L. Kaufmann, Berlin-Wilmersdorf) is a preparation containing sulphoform, an organic sulphur antimony compound 5 Gm., cholesterol 2 Gm., castor oil 50 Gm. and

ethanol 50 Gm It is used in the care of the hair especially against alopecia seborrhoica —*Pharm Zentralh*, 76 (1935), 72 (E V S)

Secale-dispert (Dispert Ltd, The Hague) is an extract of ergot prepared by the method of Krause It is marketed in the form of suppositories standardized to contain 1 mg of alkaloids each Since the Secale dispert is readily absorbed in the rectum the suppositories may be used in place of injections in abortion to promote discharge from the womb in menorrhagia, etc —*Pharm Weekblad*, 72 (1935), 73 (E H W)

Securodorm (Dr E Silten, Berlin) is a combination of butyläthylbarbituric acid ('securonal') with 'cyloralose' It is a hypnotic the dose being 1-2 tablets —*Pharm Weekblad*, 72 (1935) 73 (E H W)

Softol (Laboratoire de Pharmacologie medicale, Paris) is an organic mercury arsenic compound, the methylodide of mercuric nucleo arsenic-salicylate It is used as an intravenous injection once a week for spirochete infections —*Pharm Weekblad*, 72 (1935), 73 (E H W)

Solucamphor Debalande Ampuls (M Debalande Courbevoie-Seine) contain 0.14 Gm diethylenediaminocamphor sulphonate per cc in 1, 2, 5 cc ampuls —*Drug and Cosmetic Ind* 36 (1935), 93 (H M B)

Soxolade (Nahrmittelfabrik Munchen G m b H Berlin Charlottenburg) is a dietetic nutrient food containing 30 per cent of fat-free cocoa powder maltose amylose plant albumins egg lecithin phosphorus, iron and calcium It is used as a nerve food for the young or old, especially for pregnant and nursing women, nervousness and anemias —*Pharm Zentralh*, 76 (1935), 72 (E V S)

Specialties—Review of German, for 1934 A discussion of new German specialties which the author divides into groups according to their pharmacologic activity or use The classification includes vitamins, hormones, ointments, antiseptics, soporifics and hypnotics, and treatment of cancer The possibilities of heavy water are enumerated Some advances in pharmaceutical apparatus during the past year are described and illustrated —K SCHULZE *Scientia Pharm*, 6 (1935), 1 (M F W D)

Stannoblettes (H L Ritter and Co, Berlin Germany) These tablets are stated by the manufacturer to contain as the active ingredient chemically pure, lead-free tin oxide They are recommended for use in the treatment of furunculosis, as well as all staphylococcus infections carbuncles, acne vulgaris acne rosacea eczema, pyoderma, sycosis hordeolum abscesses of all kinds and lymphangitis They are distributed in packages of 35 and 80 tablets —*Pharm Zig*, 80 (1935), 72 (G E C)

Stomachetten (Zyma) is composed of vitamin-yeast extract and vitamin yeast powder both of which by virtue of their content of amino acids and purine compounds stimulate the flow of gastric juice In case of loss of appetite 3-4 tablets are taken 1/ hour before meal time —*Pharm Weekblad*, 72 (1935) 179 (E H W)

Thymodronal (Orgapharm Ltd Amsterdam) is a syrup made from Extract *Primulae* *Viola odoratae*, *Pimpinella* *Drosera*, *Castanea vesca* *Plantaginis* *Thymi*, *Liquiritiae* 7.5 Gm, Extract *Aconiti* *Belladonnae*, *Bryoniae* *Hyoseyami*, *Ipecacuanhae* 0.25 Gm *Sulphoguaiaecolas* *Kalicus* 4.5 Gm, Simple syrup and 150 Gm and flavoring oils It is an expectorant which is given in doses of a half tablespoonful for adults and a half to one teaspoonful for children It also appears on the market with 0.1% codeine —*Pharm Weekblad*, 72 (1935) 73 (E H W)

Thyreoid-dispert (Dispert Ltd The Hague) is obtained by the method of Krause and consists of the dry powder of the thyroid gland standardized in thyroid units by the method of Straub on white mice It appears on the market in tablets of 5 and 10 units —*Pharm Weekblad*, 72 (1935) 73 (E H W)

Valeriana-dispert (Dispert Ltd The Hague) is prepared by the method of Krause from valerian root and physiologically standardized on mice by the method of Haffner It occurs on the market in capsules the dose being 1-3 as necessary —*Pharm Weekblad*, 72 (1935) 73 (E H W)

Vaxa (Dr Boucard Paris) is a bullion vaccine used as an internal medicament Because of the unpleasant odor of this preparation, it is advised to aromatise the contents of the ampul which must be well shaken before taking In the preparation of Vaxa a number of different organisms are used *B. coli* *Streptococcus faecalis* *Staphylococcus aureus* *Streptococcus proteus* etc It is said to contain the exotoxins and endotoxins Vaxa immunizes the peritonium and is used

in *Coli* bacillosis, cystitis and other infections. A spoonful of olive oil is taken in the morning. This is followed twenty minutes later by an ampul of milk ferments and 10 minutes later by an ampul of *vava*. One half hour should elapse before breakfast is begun.—*Pharm Weekblad*, 72 (1935), 74 (E H W)

Viatol (Dr Boucard, Paris) is a vitamin preparation (mostly vitamin B) in tablet form, used as a strength reinforcing medicament for children and as a nutrient for adults. Dose, 1-2 tablets.—*Pharm Weekblad*, 72 (1935), 74 (E H W)

Viscophyll (Gelic and Co., Dresden) is a specially processed extract drop solution prepared from the choline ester of fresh mistletoe, chlorophyll and *Fucus vesiculosus*, used against hypertonic and sclerotic vessel variations and conditional maladies of the aged.—*Pharm Zentralh*, 76 (1935), 73 (E V S)

Zittmangan (Bürger) is prepared by Zyma from sarsaparilla root with the addition of manganese and sulphur. It serves as an adjuvant in arsenic-, bismuth-, mercury therapy. Dose, 2-3 tablets three times a day.—*Pharm Weekblad*, 72 (1935), 179 (E H W)

BACTERIOLOGY

Antiparalysis Serum—One Hundred Per Cent Effectiveness with. During an infantile paralysis epidemic seven hundred persons were injected with antiparalysis serum and not one developed the disease. This serum was developed by Maurice Brodie and is made through infection of a rare type of Indian monkey with virus taken from the nasal passages. The infected monkey's spinal cord is then excised and the emulsion made of it is sterilized with formalin, which makes the vaccine harmless.—*Med Rec*, 141 (Feb 1935), 212 (B S R)

Antipolomyelitis Serum—Virus Adsorbed to Alumina-Gel for Production of, in Sheep. Ether treated virus was shaken with alumina-gel (Willstaetter, Type C) at a pH 6.5. Two injections of 50 and 65 cc produced antiserum of a titer beyond 1:500.—F B GORDON, J A HARRISON and N P HUDSON. *Proc Soc Exptl Biol Med*, 32 (1935), 689 (A E M)

Antitoxic Serum—New Method of Treatment of Diphtheria with. The author attributes the high mortality in diphtheria to be due to the unsystematic use of insufficient doses of serum. He injects the serum daily without omission until all symptoms, including general symptoms, completely disappear. The method is given in detail.—A T JAROTZKY. *Med Rec*, 141 (Feb 1935), 125 (B S R)

Azochloramid—Bacterial Action of. *N N* Dichlorazodiacarbonamidine, a new chlorine compound, was tested as to its bactericidal action on *Staphylococcus aureus* and *Hemolytic streptococci*, *Cl Welchii*, *C Diphtheriae*, *Pneumococci* types I, II and III, *Ps Pyocyanica* and *Esch Coli*. Both + and - organisms were killed by low concentrations in the presence of blood serum. It can be used advantageously for general bactericidal purposes but its action is impaired in the presence of laked red cells.—SCHMELKES and HORNING. *J Bact*, 29 (March 1935), 323 (A H B)

Coli-Aerogenes Group—Comparative Studies of Presumptive Test Media for. Presumptive tests for 201 pure strains of *Escherichia*, *Aerobacter* and *Citrobacters* were tested for gas formation in plain lactose broth, brilliant green lactose peptone bile, crystal violet buffered broth and fuchsin broth. When small inocula were used (less than 50 organisms per tube) lactose broth and brilliant green lactose peptone bile gave positive tests after twenty four hours of incubation at 37° C for all 201 strains tested. In crystal-violet broth after forty eight hours of incubation using similar small inocula, only 49 per cent of these strains gave positive tests. Very few strains formed gas in fuchsin broth when small inocula were used, and with relatively large inocula only 33 of the 201 strains were able to form gas in forty eight hours.—I SHUNK. *J Bact*, 29 (1935), 163 (A H B)

Fungicides—Clinical Implications from the Testing of. Fungicidal determinations with 1% concentration of tetraiodomethanamine (I), thymol (II) and a mixture of I and II (III), iodine (IV), salicylic acid (V), benzoic acid (VI), boric acid (VII), Arning's tincture (VIII) and sodium chloride (IX) were made using test-tubes for the culture media which had been lined with collodion impregnated with the chemical to be tested. I, II, III, IV, V and VI completely inhibited growth and acted to some extent as fungicides. VII delayed growth and VIII and IX had no effect. When the collodion was not in contact with the medium but was present only in the upper portion of the tube, II alone inhibited growth. In treatment of parasitic infections of

the skin, salicylic acid is ideal in meeting the requirements of a fungicide, boric acid, that of a fungistat since both of the chemicals diffuse rapidly through the skin and readily manifest themselves in the urine—H SHARLIT *Arch Dermatol Syphilol*, 31 (1935), 217 through Squibb *Abstract Bull* 8 (1935) A 294 A H B

Germicidal Substances—Comparison of Resistance of Bacteria and Embryonic Tissue to, I Merthiolate Bacteria and chick embryo hearts were tested separately The phenol coefficient of merthiolate was found for *E Typhi* to be 50, for *Staph aureus* 70 The highest dilution showing no tissue growth was 1 840 for phenol, 1 176,400 for merthiolate The toxicity index, calculated from both results, was found to be for phenol 10 5 and 12 0, for merthiolate 44 1 and 35 3—A J SALLE and A S LAZARUS *Proc Soc Exptl Biol Med*, 32 (1935), 665 (A E M)

Immunity—Relative Importance of Reticulo-Endothelial Tissues and Circulating Antibody The relative importance of the circulating antibodies as compared with the reticulo endothelial tissues in immunity is studied by noting the primary clearance of virulent streptococci *B Anthracis*, *Pneumococcus* type III and the *B Freidlander* from the blood stream and the presence or absence of protective antibodies conferring a passive immunity It was found that the reticuloendothelial tissues can completely clear the peripheral circulation and prevent secondary bacteraemia in the absence of any germicidal power of the whole blood The positive conclusion is of far-reaching importance regarding the use of antisera in treatment of infections, in that the state of the tissues is the chief factor in establishing immunity—F TEALE *J Immunol*, 28 (1935), 133 (A H B)

Pathogenic Fungi—Effect of Dyes on Colonies of Certain The medium (4% peptone, 1% dextrose, 1½% agar pH 5 6) was prepared with the following dyes 2% fluorescein, 1% methylene blue and 1% eosin Y, ½% neutral red, ½% janus green and ½% Wright's stain suspension Growth was more profuse on acid stains The absorption of different dyes is described The microscopic picture was often better, than when specimens grown on ordinary media were stained Double staining was frequently observed—J W WILLIAMS and L GREEN *Proc Soc Exptl Biol Med*, 32 (1935) 625 (A E M)

Pathogenic Fungi—Scalp Products and Hair of Men and Women as Culture Media for Certain Hair autoclaved with water and hair extracts were used A large number of fungi showed more or less prompt development on this medium—J W WILLIAMS *Proc Soc Exptl Biol Med*, 32 (1935) 624 (A E M)

Polomyelitis—Active Immunization Against Tests on human volunteers in which 1 to 3 doses of 5 cc of a 10 per cent virus, inactivated with 1 per cent formalin, were given showed no systemic reaction Similar tests on children showed no discomfort or general reaction followed by appreciable antibody response—M BRODIE *J Am Pub Health Assoc*, 25 (1935), 54 (A H B)

Polomyelitis—Active Immunization against, with Germicidally Inactive Virus Five cubic centimeters of 10% suspension of infective cord of formalized virus proved the best immunizing dose for active immunization of monkeys against intracerebral inoculation of one or more infective doses of the virus of polomyelitis—M BRODIE *J Immunol* 28 (1935), 1 (A H B)

Scarlet Fever Antitoxin—Concentration of The best method of concentration of scarlet fever antitoxin is that followed in the production of diphtheria antitoxin, using 45% ammonium sulphate and heating at 63° C—CIANCARULO and MALCOLM *J Immunol*, 28 (1935) 47 (A H B)

Staphylococcus Toxoid Prepared by treating staphylococcus toxin with formaldehyde and standardized so that each cc contains the toxoid derived from at least 1000 necrotizing doses of toxin It is a clear straw colored fluid used for the treatment and prevention of recurrent boils and carbuncles, and pustular acne particularly when associated with furunculosis It should not be used where there is generalized blood stream infection with staphylococcus and should not be used when it has become cloudy or turbid It is supplied by E R Squibb & Sons, New York City, in 5 cc rubber capped vials—*Drug Circ*, 79 (Mar 1935), 32 (T G W)

Typhoid Prophylaxis—Efficacy of, in United States Army The Army vaccine may be improved by reverting to a monovalent strain vaccine and increasing its bacterial content Army

and Navy statistics both prove the undemable value of typhoid prophylaxis—R. PATTERSON
Am J Pub Health, 25 (1935), 258 (A H B)

Water—Bacteriological Control of A review article concerned chiefly with methods used at the Swedish State Veterinary Bacteriological Control Laboratory—H. HEDSTRÖM *Farm Recty*, 34 (1935), 190 (C S L)

Whooping-Cough—Immunization against The morality of infants under 1 year old afflicted with whooping cough may reach 15% The disease causes more deaths than diphtheria, measles or scarlet fever About $\frac{1}{4}$ of the annual 6000 fatal cases occur in children under three years old The immunizing pertussis vaccine is made from recently isolated hemolytic strains of Bordet-Gengou bacillus The medium contains about 20% of freshly defibrinated human blood The 48 hour growth is scraped off and suspended in physiological sodium chloride solution containing 0.5% phenol After a week the vaccine is diluted to contain 10,000,000,000 bacilli per cc The active immunity conferred seems to depend on the potency and dosage of the vaccine and the interval (at least 4 months between) injection and exposure The total dosage after 6 months of age is 8 cc, one cc is injected just under the skin in the deltoid region of each arm, one week later 5 cc are injected in theiceps region of each arm The optimal age of immunization is probably 7-10 months Reactions are chiefly local, although there may be a transient rise in temperature Over 650 children have been immunized, including 150 infants 3 months old, each of whom received a total of 6 cc with negligible local and systemic reaction The infants have not yet been exposed and it cannot be detected whether immunity was conferred—L. W. SAUER *Am J Diseases Children*, 49 (1935), 69, through *Squibb Abstract Bull*, 8 (1935), A-278

Whooping-Cough—Significance of Bacteriological Methods of Diagnosis and Control of In the preparation of Pertussis Vaccine the cultures are isolated from recent cases which show high titre agglutination, with a smooth strain antiserum, and with a final titre of 1:10,000 to 1:25,000 against rabbit serum using the rapid test The test antigen is a saline suspension of *B. pertussis*, 1 billion per cc of living virus, which gives a typical skin hemorrhagic necrosis within 24 hours, at the site of inoculation The organisms are killed and preserved with merthiolate 1:10,000 The cough plate diagnosis is available to physicians for finding the etiological organisms Statistics indicate the greatest period of infectivity to be the first 3 weeks, with gradual decline from then on—KENDRICK and ELDERING *J Am Pub Health Assoc*, 25 (1935), 147

(A H B)

BOTANY

Fungi. A commemorative address concerning the poisonous fungi such as the Amanita and Boletus—W. FRIESE *Pharm. Zentralh.*, 76 (1935), 81 (E V S)

CHEMISTRY

GENERAL AND PHYSICAL

Emulsions—Studies in—III Lipin-Containing Substances as Emulsifiers Aqueous dispersions of lipins from various sources and of various ages yield dual emulsions on shaking by hand with fat solvents At oil-rich phase volume ratios, both types of emulsions appear to be simultaneously present (possibly as complex emulsion systems), as far as can be judged by drop tests It is thought that a possible explanation of this behavior might be the presence in the lipins of opposite type emulsifiers, which simultaneously exert their actions to some extent incidentally of each other—R. M. WOODMAN *J Soc Chem Ind*, 54 (1935), 70T (E G V)

INORGANIC

Calomel—Physical and Chemical Investigation of Sixteen specimens of calomel of at least seven different origins were examined All were assayed and other U S P tests applied All were examined microscopically Detailed descriptions are given The different types of calomel described in the literature, differentiated by their methods of manufacture and their titles are discussed The survey showed the high quality of the specimens and illustrated variance in size and type of particles—C. H. LAWALL *J Am Pharm Assoc*, 24 (1935), 97

(Z M C)

Potassium Permanganate—Electrolytic Manufacture of For some time it has been considered difficult to produce potassium permanganate commercially by electrolytic methods. Several processes have been evolved and the outcome of experimentation has been the modern method of electrolytically producing the pure salt from the crude metal. The process is as follows. Anodes containing 80% of manganese are suspended in the middle compartment of a diaphragm cell, made by dividing a sheet iron tank into three chambers by means of prepared asbestos paper diaphragms. The cathodes are made of iron, while the electrolyte is made up of two different solutions. The catholyte is composed of a solution of caustic potash and the anolyte consists of potassium carbonate. The current efficiency tends to rise somewhat with the anodic current density, and requires to be accurately registered. The plant consists of cathodes of sheet iron surrounded by porous diaphragms. The temperature of the bath is maintained throughout the day by a steam coil, and the electrolytes are kept in motion. The main features which influence the course of the electrolysis are the composition of electrolyte and anode, the current density and the temperature. As the manganese content in the anode increases, the current efficiency rises rapidly but the voltage only increases very slowly, and the energy consumption per pound of permanganate produced tends to fall. The final stages in the process consist of concentrating the electrolyte and recovering the crystals of permanganate after which the mother liquors are returned to the electrolysis bath.—*Chem. and Drug* 122 (1935), 270 (T G W)

Sodium Hypochlorite—Easy Production of A brief note on the production of sodium hypochlorite by passing a solution of ordinary salt and sodium bicarbonate through an electric cell.—*Med. Rec.*, 141 (Feb 1935) 162 (B S R)

ORGANIC

Alkaloids

Cocaine—Reactions of Solutions of, on Sterilization and Storage A brief review of the literature on the subject is given along with criticisms. The chief cause for the disagreement of the literature lies in inaccurate methods of analysis of the cocaine solutions. A method of analysis as applied to morphine is discussed and applied to cocaine. The method used is briefly as follows. 10 cc of a 1% solution of cocaine hydrochloride is treated with 10 cc of isopropyl alcohol-chloroform mixture (1 volume and 3 volumes) made alkaline with 0.5 Gm sodium carbonate and shaken vigorously for one minute. The organic solvent drawn off, the extraction repeated twice, the combined extractive being evaporated on a water bath, the residue dissolved in excess of 0.1 N hydrochloric acid and back titrated with 0.1 N sodium borate solution. An examination of the dissociation constants reveals that the substances formed in the hydrolysis are too weakly basic to affect the end point when methyl orange is used in the titration and the method is thus adaptable to the determination of cocaine in solutions partially hydrolyzed. The determination of benzoic acid is as follows. 2 cc of a 1% solution of cocaine hydrochloride are completely hydrolyzed by boiling with 2N sodium hydroxide, the solution is transferred quantitatively to a separatory funnel, is acidified to methyl orange using 2N hydrochloric acid, extracted three times with the isopropyl alcohol-chloroform mixture, the combined extractive evaporated on a water bath, cooled and titrated with 0.1 N alkali using phenolphthalein. Using these two determinations the progress of the hydrolysis of cocaine solutions is studied under different conditions, the results being compiled in tables. It is shown that if alkali free glass ampuls are used, 1% solutions of cocaine hydrochloride in distilled water can be sterilized at 100° for 30 minutes without hydrolysis, and if it is made 0.001N with hydrochloric acid it can be sterilized in a steam autoclave at 120° for 20 minutes. Contrary to the literature, it is shown that the presence of phosphate as a buffer does not stabilize the solution but rather accelerates the hydrolysis. The effect of long standing of solutions of cocaine prepared as above is taken up and also the effects of filtration of similar solutions through a Seitz filter.—S A SCHOU and E HERN *Pharm. Acta Helv.*, 10 (1935) 31 (M F W D)

Novocaine—Reactions of Solutions of, on Sterilization and Storage Although novocaine was for several years the only local anesthetic in use, the knowledge of its stability and the effect of sterilization on its solutions is quite limited. A few of the methods of the estimation of novocaine reported in the literature are reviewed and their defects pointed out. Novocaine (the hydrochloride of *p* aminobenzoyl diethylaminoethanol) on hydrolysis yields *p* aminobenzoic acid

and diethylaminoethanol, and the pH of the solution obtained is the result of the basic tendency of novocaine and the amine liberated and the acidic tendency of the p aminobenzoic acid. Novocaine could thus be determined by the same method as cocaine as given by S. A. SCHOU and E. HEIM [*Pharm Acta Helv*, 10 (1935), 31]. In determining the novocaine in a solution having undergone partial hydrolysis, several difficulties are encountered because of the mixture of possible substances, and in the addition of the proper amount of acid so as to precipitate quantitatively the p aminobenzoic acid. After several tests the following procedure was worked out: 2 to 10 cc. of a solution of novocaine is treated with 0.5 Gm. sodium carbonate in a separatory funnel and shaken out three times with isopropyl alcohol-chloroform (1 volume and 3 volumes), the extractive being filtered into and combined in a second separatory, the solution treated with 2*N* hydrochloric acid drop by drop until a red color appears with methyl orange, then shaken out three times with the same organic solvent, the extractive being filtered and evaporated on a water-bath, the residue dissolved in water and titrated with 0.1*N* alkali using phenolphthalein (p aminobenzoic acid), the extractive of the alkaline solution is shaken out with 10 cc. 0.1*N* hydrochloric acid, and the excess of acid then back titrated with 0.1*N* alkali using one drop of methylene blue and two drops of methyl red (novocaine and amine). The influence of sterilization on 2% solutions of novocaine in water in 0.001*N* hydrochloric acid, and in the presence of 0.15*M* phosphate is compiled in a table. The solution in 0.001*N* hydrochloric acid is most stable, only 2% of the novocaine being split and the pH not changing at all after autoclaving at 120° for 20 minutes. For maximum stability the pH of the solution must not exceed 5.0 and the ampuls must be of Jena glass. It was found that 0.01*N* hydrochloric acid produced practically no hydrolysis, and 0.1*N* only a slight amount but 1*N* destroyed more than half of the novocaine on autoclaving at 120° for 30 minutes. Analysis of several old samples of solution ranging from 0.5% to 5% shows that the solution is fairly stable, a maximum of 5% deterioration being shown by a sample seven years old.—J. ABILDGAARD [*Pharm Acta Helv*, 10 (1935), 38] (M F W D)

Strychnine Sulphate—Adsorption of, by Various Charcoals and by Lloyd's Reagent. Research was undertaken to determine diminution of potency of strychnine sulphate solutions in contact with commercial charcoals and with Lloyd's reagent. Seven charcoals were tried. Experimental work is described. There was wide variation. One charcoal showed complete adsorption up to nearly 5 Gm. per L. Willow charcoal which is the type usually used in pharmaceutical preparations was the poorest, taking up only 11 per cent when the concentration was 1 Gm. per L. Lloyd's reagent took an intermediate place and differed from the others in that the percentage adsorbed was only 11 per cent when the concentration was 1 Gm. per L. One charcoal required more than 24 hours to reach an equilibrium. Some absorbed less salt from alcoholic than aqueous solution. Langmuir's equation represents the adsorption curves better than Freundlich's.—J. F. SUCHY and R. V. RICE [*J. Am. Pharm. Assoc.*, 24 (1935), 120] (Z M C)

Essential Oils and Related Products

Cymbopogon Georngu—Volatile Constituents of. The volatile oil derived from the inflorescence of the graminaceous plant *Cymbopogon Georngu*, Honda, has as constants $\alpha_D^{13} - 34.96^\circ$, $d_4^{20} 0.9585$, $n_D^{17} 1.52128$, acid no. 0, sap no. 12, sap after acetyl 30.6, methoxyl 25.42%. Of the terpenes present camphene was identified by conversion into iso-borneol, m. p. 212°. Sesquiterpenes constituted an important portion of the oil. The cadinene present, $\alpha_D^{25} - 106.11^\circ$, yielded a hydrochloride, m. p. 117° and a hydrobromide m. p. 123°. A small quantity of borneol was isolated. Elemicin, estimated from the methoxyl content of the oil, amounted to 57% iso-elemicin dibromide, m. p. 89° to 90°, permanganate oxidation yielded gallic acid trimethyl ether, dibydroelemicin, by reduction with platinum oxide catalyst, had b. p. 120° to 125° at 3 mm. The b. p. recorded by Will (*Ber. d. d. Chem. Gesell.* 21 (1888), 2025) should probably read 264°.—T. KARIYONE and A. MAJIMA [*J. Pharm. Soc. Japan* 55 (1935), 14 to 16] (R E K.)

Oils of Flacourtiaceae—Actual Situation of Production of, in View of Their Utilization in Therapeutics. A survey of the conditions surrounding the cultivation of the plant and the therapeutic use of the oils obtained from certain members of the Flacourtiaceae family. Remarks on the method of production of the oil, as carried out at the Pondicherry Laboratories, are given. The author believes more intensive studies in the cultivation of the plant should be instituted.

and attempts should be made to improve the oil from the standpoint of its acid content—M FRANCOIS *Bull sci pharmacol*, 42 (1935), 24 (C T I)

Fixed Oils, Fats and Waxes

Chaulmoogra Oils in Pharmacopœas and in Commerce The reaction of Dymock (H_2SO_4 causes the separation of a red resinous material leaving the oil green) and the index of refraction ($n_D^{20} = 1.4842-1.4888$) should be included in the requirements of the Pharmacopœa. The inferior limit of acidity and the superior limit of optical rotation should be omitted. The 10% solution in chloroform (10 Gm. in 100 cc.) must give a rotation of at least $+5.12'$ —A and C CHALMETA *La Farm Mod*, 46 (1935), 63 and 94 (A E M)

Chinese Insect Drug, Chiu-Hsiang-chung—Study of Oil of The insect yielding the Chinese drug Chiu Hsiang chung is *Aspongopus chinensis*, Dallas, which is found in Southern China and Formosa. The name first appears in the "Sheh sheng chung miaofang" and afterwards was introduced into the 'Pan tsao kan-mu' one of the old Chinese Materia Medica. General Ho Chung of Szechuan Province mentioned this drug about 1526 in his Biography of the Min Dynasty which proves that the drug had come into use more than 400 years ago. The only material examined was in ether extract of the insect. Stearic, palmitic and oleic acids were identified. They exist partly combined and partly free. The oil also contains a small amount of an aldehyde or ketone, to which the peculiar odor of the oil is attributed—L C WAUNG *J Pharm Soc Japan* 55 (1935), 8 to 14 (R E K)

Cod Liver Oil—Iodine Content of The iodine content of twenty representative samples of American cod liver oil was determined. The iodine apparently varies with the locality in which the oil is produced. The average values for the different localities in parts per billion are: Nova Scotia 13 260, Gaspe Peninsula 11 250, Newfoundland 8360, the area around George's and Brown's Banks 5340, Massachusetts 4930 and Maine 3950. Remington's values for the iodine content of fruits and vegetables of South Carolina are reproduced—A D HOLMES and R E REMINGTON *Am J Diseases Children*, 49 (1935), 94, through *Squibb Abstract Bull* 8 (1935), A-251

Fat—Production of, from Glucose by Molds Cultivation of *Penicillium javanicum* van Beijma in Large-Scale Laboratory Apparatus. A survey of sixty one organisms of the genera *Aspergillus* and *Penicillium* showed nine *Penicillia* and one *Aspergillus* whose mycelia contained more than 15 per cent ether soluble material. An intensive study of *Penicillium javanicum* van Beijma showed that its mycelium may contain as much as 41.5 per cent fat, depending on culture conditions. In flask cultures, media containing 40 per cent glucose gave mycelia of highest fat content. A cabinet for experimental study of shallow pan fermentations is described, and representative results of culture experiments conducted therein are presented. In such cultures, increase of the glucose content of the medium apparently does not increase the fat content of the mycelium of *P. javanicum* as it does in flask cultures. The free fatty acid content of the fat obtained from the mycelium grown on 30 and 40 per cent glucose solutions is much higher than that of fat similarly derived from 20 per cent glucose solutions. In addition to fat the mycelium of *P. javanicum* yielded a complex carbohydrate and a chitinous material—G E WARD, *et al* *Ind Eng Chem*, 27 (1935), 318 (E G V)

Fats and Oils—Spoilage of III Rancidity and Constitution of Oleic and Elaidic Acids. A continuance of the review and discussion from the *Allg Oel- und Fett-Ztg* (1933), 11-12, of the literature on the properties of oleic and elaidic acids relative to the molecular structure—R NEU *Pharm Zentrallh*, 76 (1935) 65 (E V S)

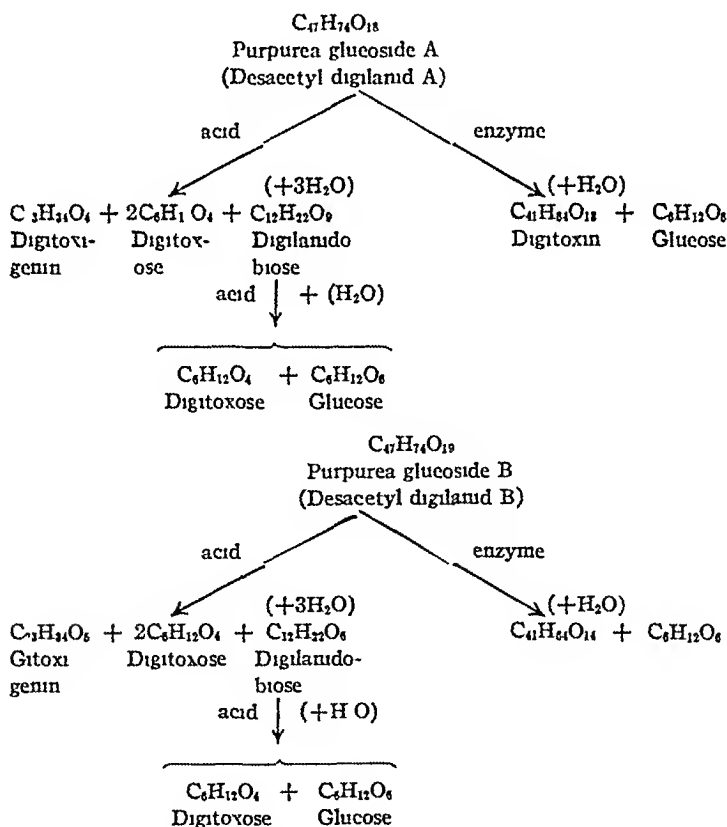

Glycosides, Ferments and Carbohydrates

Beechwood Lignin—Product of Reaction of Carbohydrates in the Determination of The difference between the woods of red beech and pine chemically is in the high per cent of methoxyl groups and low per cent of lignin (beech 24%, pine 29%). The theoretical yield of lignin in beechwood was calculated at 27-33% against the actual yield which was 24%. Lignin is not found in woods as such but is only a by-product of the chemical reaction. The beechwood was mixed with acids and most of it dissolved. The mixture was diluted with water, a precipitate formed. The product was methylated cellulose anhydride with a formula of $2C_6H_{10}O_5 \cdot H_2O$ with one methoxyl and 2 cellulose anhydride groups. At 15-20° with concentrated hydrochloric acid this changed to lignin which had a methoxyl group content of 21%. This proved that the collected beechwood lignin was not a constituent of the wood but a by product of the chemical reaction.

tion, formed with a low temperature and the addition of an acid. A change of methoxyl group is also evident. The appearance of quantities of cellulose anhydride shows that hydrolysis is not completed in the wood. The reaction of methoxyl group during the addition and reaction of acid has been proven. Oxidation of woods is not easily explained. There is a possibility of a chemical affinity between the carbohydrate and the process of oxidation.—R. S. HILPERT and H. HELLMAGE, *Ber.*, 68 (1935), 380 (G. B.)

Chenopodium Ambrosioides L.—Saponins of. Some plant parts of *Chenopodium ambrosioides* L. contain saponin, especially the roots (2.5%). The seeds, leaves and branches are relatively poor in saponins. The principal constituent is a neutral saponin, but it also contains a saponin which gives an acid reaction. For purification of the saponins, 96% alcohol was found to be the best solvent to use. The pure neutral saponin is amorphous, readily soluble in dilute alcohol. The m. p. is 196–200°. The product has little hemolytic power (hemolytic index 1/40,000). The saponin content of the root increases naturally with the age of the plant, but it can be further increased by the use of a fertilizer.—S. GRIFINGER, *Wladomosci farmac.*, 61 (1934), 275–277, 289–291, through *Chem. Zentr.*, 106 (1935), 746 (G. B.)

Digitalis Purpurea—Glucosides of. *Purpurea* glucosides A and B are claimed to be the true glucosides of *Digitalis purpurea*, their relation to the other so-called glucosides of this plant being given below.

These glucosides differ from the corresponding ones present in *D. lanata*, i. e., digiland A and B, by having one acetyl group less. It seems that the C-series of *lanata* glucosides disclosed in the form of digitoxin, are not present in *Digitalis purpurea*. The genuine glucosides of *Digitalis purpurea* have thus far been obtained only in amorphous form. Details of the separation (differential solubility) and isolation of the two glucosides as well as their enzymatic and acid hydrolysis are given.—A. STOLL and W. KRIES, *Helv. Chim. Acta*, 18 (1935), 120, through *Squibb Abstract Bull.*, 8 (1935), A-360.

Lignin—Presence of, in Leaves The principal constituents of leaves are mostly cellulose and a little lignin, which are usually found in the fibrovascular bundles. In order to better establish the properties of the framework (venation) of leaves experiments were tried with leaves of beech, plane and hazel, the type leaves used were green and yellow. To remove wax and resin organic solvents were used. The extraction using either water or benzol alcohol as solvent proved higher in the green leaves than in the yellow leaves. Trichlor-ethylene dissolves out more extract from the yellow leaves. This would indicate that the carbohydrate undergoes further changes so that more extract is obtained with organic solvents than water. The same changes occur using acids. Such variations are probably due to chemical changes in the leaves. All leaves were collected in late fall, when the proteins in leaves underwent chemical changes. The lignin obtained from leaves is 59–60% poorer in carbon than that lignin obtained from woods. Lignin from leaves is more soluble in water than that from straw and woods. Chemically leaf lignin is similar to wood lignin. Lignin combines readily with acids and so makes the material easy to work with. Different quantities of lignin are extracted from leaves when using sulphuric or hydrochloric acids. The quantity of lignin obtained with acids after the leaves have been extracted with benzol alcohol solvent is different. In green leaves the total extract is greater in lignin output than that found in yellow leaves. Sugars under the influence of acids and low temperature become resinous and hard so that they cannot be separated out together with lignin. For plant parts having no lignin a low temperature is useless since such plants hydrolyze poorly. Throughout the experiment 72% sulphuric acid was used. Sodium sulphide proved to be a solvent for cellulose especially on some plants belonging to the family Gramineae. It was then used as a solvent for fibrous leaves. The mesophyll of leaves is resistant to the solvency of sodium sulphite but fibrovascular bundles completely dissolve in it. Sodium hydroxide is not such a good solvent for cellulose. The product obtained with either sodium sulphite or sodium hydroxide is not pure cellulose but in combination as hemicellulose. The method of detecting pure cellulose of Cross and Bevan was employed, not more than 19% of pure cellulose was obtained although 80% of the extract from leaves went into solution. This makes evident the theory that most of the lignin occurs in chemical combination with other carbohydrates. Wood-lignin contains from 13–15% of methoxyl groups (OCH_3) in contrast to leaf-lignin of only 4% of (OCH_3) group. Methoxyl groups under the influence of acids become hard and refuse to go into solution. The framework (venation) of foliage plants contain hemicellulose, in contrast to alfalfa whose cellulose is readily soluble in caustic soda. The leaf of alfalfa trails to the ground, therefore must support itself, hence its framework is composed mostly of cellulose, the same is true in *Chamerops humilis*, etc., which have no stems. The leaves of these plants contain cellulose fibres which are put in solution with caustic soda. Cellulose and not lignin give support and strength to leaves.—R. S. HILPERT and R. WAGNER. *Ber* 68 (1935) 371 (G. B.)

Maple Syrup—Aerobacter Aerogenes as Cause of Ropiness in A group of bacteria was isolated from the sap of *Acer saccharum* which, when inoculated into sterile sap or dilute maple syrup, produced a ropy maple syrup upon being concentrated to the consistency of syrup. Since these bacteria were isolated from the sap from which the ropy maple syrup was produced in the sugar bush it is evident that they were responsible for the condition. The morphological, physiological and cultural characteristics of the bacteria responsible for this condition corresponded in all essential details to those of *Aerobacter aerogenes*. The addition of an amount to acetic acid of approximately the acidity found in the fermented sap did not influence the consistency of the evaporated sap. The addition of a similar amount of lactic acid did influence its consistency. Neutralizing the acidity of fermented sap reduced somewhat the ropy condition of the concentrated sap.—F. W. FABIAN and H. H. BUSKIRK. *Ind Eng Chem* 27 (1935), 349 (E. G. V.)

Maté—Tannin in The composition of maté is of considerable importance because of its wide use in South American countries as a beverage in a manner similar to our very popular tea. The authors of this paper have made an elaborate investigation of its tannin content and summarize their conclusions as follows. (1) It has been shown that maté is completely free from genuine tannin. This is a matter of considerable importance, in view of the effects of ordinary tea upon the digestion. (2) It has also been shown that maté contains an appreciable amount of a natural yellow plant coloring matter. It is reasonably certain that this coloring matter is a derivative of flavone. (3) Certain evidence has been obtained pointing to the presence in maté of caffetannin or some closely allied compound. (4) Comparisons have been made with coffee and

tea, and attention has been drawn to important differences and similarities"—W A WOODARD and A N COWLAND *Analyst*, 60 (1935), 135-145 (A H C)

Primula Root Data are given showing the saponin content of the root of *Primula veris* as revealed by the hemolytic test of Kofler and Adam—A TOMINGAS *Pharmazie*, 14 (1934), 197-212, through *Chem Zentr*, 106 (1935), 594 (G B)

Saponins and Sapogenins—III Sapogenins Obtained from *Chlorogalum Pomeridianum* Hydrolysis of the alcoholic extract of the bulbs of *Chlorogalum Pomeridianum* or California soap plant, a plant used as fish poison by the California Indians, yielded two sapogenins. One, reported for the first time and named chlorogenin by the authors, has the formula $C_{26}H_{42}O_8$, melting point 273-276°, and isomeric with gitogenin. The other has the formula $C_{25}H_{40}O_8$ and appears to be identical with tigogenin—P LIANG and C R NOLLER *J Am Chem Soc*, 57 (1935), 525 (E B S)

Sugars and Sugar Mixtures—Hygroscopicity of A definite relationship between the sucrose, invert sugar and water content of various sugars and the relative humidity of the surrounding atmosphere has been found, and the equilibrium points have been graphed. The equilibrium relative humidity or vapor pressure of pure sucrose, dextrose, fructose, invert sugar or sucrose invert sugar mixtures with varying percentages of water can be determined directly from the graph—J H DITTMAR *Ind Eng Chem* 27 (1935), 333 (E G V)

Other Plant Principles

Brucella Abortus, Toxic Principles—1 Preparation, Toxicity and Biochemical Nature of Alcoholic Precipitate Alcoholic precipitates were prepared from shaken and filtered suspensions of *Brucella abortus*. These precipitates were highly toxic for guinea pigs by intraperitoneal injection. The toxic and antigenic fraction was water soluble. Filtration did not modify the toxic effect. Dialysis removed some of the lethal substance in one trial but did not affect the suspension in a subsequent experiment. Varying volumes of alcohol did not affect the toxic and antigenic qualities of the precipitate. Preparation of these precipitates on several occasions gave rise to symptoms simulating undulant fever in a hypersensitive human subject. Preliminary biochemical examination suggested that the precipitate consisted almost entirely of carbohydrates—R GWATEIN *Can J Research*, 12 (1935), 115 (S W G)

Digitalis—Flavones from A flavone dye luteolin or 5,7,3',4'-tetrahydroxyflavone has been reported to be obtainable from *Digitalis purpurea* and an unidentified dye, $C_{15}H_{10}O_6$, has been isolated from *D lutea*. Karrer isolated an entirely different flavone which he calls thapsin, from the dried, pulverized leaves of a Spanish species of *Digitalis* which is probably *D Thapsi*. The new dye crystallized from hot glacial acetic acid in beautiful, lemon-yellow prisms, m 224° (uncorr). It proved readily soluble in chloroform and methyl acetate, less soluble in alcohol, difficultly soluble in dilute alcohol and in ether, and insoluble in water and petroleum ether. It dissolved in alkalis with a yellow color but could be reprecipitated with acid. From a study of the decomposition products of the methylation and ethylation products of the dye the probable structure was arrived at—W KARRER *Helv Chim Acta*, 17 (1934), 1560, through *Squibb Abstract Bull*, 8 (1935), A-359 (S W G)

Phosphatide Preparations A phosphatide material such as that derived from grain or vegetable material is added to a neutral liquid such as benzene or alcohol and then mixed with dried purified and ground germs of grain. The product is a powder suitable for therapeutic use—R ROSENBUSH and G REVEREY *U S Pat* 1,988,050, Jan 15 1935 (S W G)

Phytochemical Notes—No 112 Preliminary Chemical Examination of *Corydalis Aurea* The air dried herb was extracted with alcohol and this extractive studied. Dimyrstylcarbinol was isolated. An optically active alkaloid colorless in sulphuric acid red with nitric was found. Determination of methoxy groups gave 33.47 and 32.7 per cent. An optically inactive alkaloid probably identical with a previously reported one, $C_{16}H_{25}O_4N$ shows four methoxyl groups. An insoluble optically inactive alkaloid containing no methoxy groups seemed similar to one which Chou compares to protopine—H EPPSON *J Am Pharm Assoc* 24 (1935), 113 (Z M C)

Vegetable Lecithin—Antioxidant Properties of Vegetable lecithin is shown to possess antioxidant properties in vegetable oils where the autoxidation is catalyzed by an active metal. It is believed that it may serve as an efficient antioxidant in the protection of edible oils if used in

the amounts of 0.05 to 0.1 per cent by weight —E I EVANS *Ind Eng Chem*, 27 (1935), 329 (E G V)

Unclassified

Acidum Aceticum This article is No 3 of a series of extended reviews of the organic, chemically pure substances official in the Belgian Pharmacopœia. The review is a very complete one and is divided into the following sub heads: Synonyms, History, Foreign Pharmacopœias, Preparation, Physical Properties, Chemical Properties, Identification Reactions, Official Requirements, Uses, and Literature. Each division is further subdivided and its subject matter is discussed at length with equations, calculations, tables, etc —V EVRARD *Pharm Tijdschrift* 13 (1935), 4-15 (E H W)

Amine Salts of Antimonic and Benzenestibonic Acids Powders (colorless to yellowish) suitable for use by injection against infectious diseases. Obtained by reaction of an antimony acid or a stibonic acid, such as a benzenestibonic acid such as $\text{RSbO}(\text{OH})_2$, where R is a phenyl radical which may be substituted by halogen, amino, substituted amino, hydroxyl groups or by reaction upon the acids of antimony in their higher molecular complex state of a primary, secondary or tertiary amine such as methylamine, diethylamine, peiperazine, quinine etc at room temperature or at water bath temperature. The two components are allowed to react either in aqueous solution or in a suitable organic solvent, such as methyl or ethyl alcohol. It is best to finely suspend the organic or inorganic antimony acid in water and introduce in small portions an amine until the whole of the antimony acid has dissolved. The quantities of the two components of the reaction may be varied generally less than an equivalent of the amine calculated on the stibonic or antimonic acid being sufficient, due to the high molecular state in which the acids of antimony generally are present. The complex state prevents the representation of the formulas of the products. The reaction between the antimony acids and the amines appears as a neutralization of the acidity of the antimony acids by the amines. The new compounds may be obtained by evaporating their solutions to dryness or by adding an organic precipitant, such as ether or acetone —H SCHMIDT (to Winthrop Chemical Co.) U S Pat 1,988,632, Jan 22, 1935

Amines and Diamines with Ethylene Grouping—Chemical and Physiological Study of A review giving methods of preparation and the physiologic properties of these amino compounds —G BENOIT and R HERZOG *Bull sci pharmacol* 42 (1935), 34, 102 (C T I)

2-Aminobenzimidazole—Structure and Derivatives of 2-Aminobenzimidazole is prepared from *o*-phenylenediamine in aqueous suspension and freshly prepared bromocyanogen. It is condensed with diethylmalonyl chloride in anhydrous pyridine solution giving 1 diethylmalonyl 2-amido benzimidazole, melting point 243°C . (I) The physiological action of this derivative of barbituric acid derivative is being investigated. Treatment with aqueous alkali opens the ring presumably between the N atom common to both rings and the vicinal carbonyl group to give

I

II

2 benzimidazolyl amido diethyl malonic acid

an acid melting point 214° . (II) Treatment with acetic anhydride removes a molecule of water from II and gives the ring form again. The methyl ester of II melting point 116° is prepared by saturating an ether solution with diazomethane. With carbon bisulphide an alcoholic solution of I gives after 50 hours heating 2,2-benzimidazolyl thiourea melting point 208° . These reactions characterize I as 2-aminobenzimidazole with a primary amine grouping, rather than as phenylene guanidine. Benzaldehyde reacts with I to give a product not completely characterized —GIUNIO B CRIPPA and GIULIO PERRONCITO *Gaz Chim Italiana*, 65 (1935) 38-43 (A E W)

Antimony Compounds—Complex Pentavalent, with Aromatic Polyhydroxy Compounds The Compounds are prepared by causing antimonie acid or a water-soluble salt to react with an aromatic polyhydroxy compound containing at least two hydroxyl groups in ortho positions to each other and being substituted by at least one acid group capable of forming a water soluble salt, and which polyhydroxy compound may be otherwise substituted. Suitable aromatic acids are pyrocatecholmono- and disulphonic acid, pyrogallolmono and disulphonic acid, pyrocatecholcarboxylic acid, protocatechuic acid, gallic acid, etc. The quantities of the two components reacting with each other may be varied within wide limits, the proportions used determining the antimony content of the products. Generally molecular quantities of reactants are used. The process is carried out by dissolving the reactants in water and heating the reaction mixture preferably on a water bath for some hours. When starting with a water soluble salt of an aromatic α dihydroxy carboxylic or sulphonic acid and a water-soluble antimonate, the complex compound is formed immediately after mixing the components. Several examples with details of procedure are given—H. SCHMIDT (to Winthrop Chemical Co.) U. S. Pat. 1,988,576, Jan. 22, 1935.

Calcium Gluconate Solutions—Stable Clear, stable, sterile, supersaturated aqueous solutions suitable for intramuscular injections free from irritation of the tissues contain calcium gluconate 4–20 and calcium mannate 1–3%. U. S. Pat. 1,989,565. U. S. Pat. 1,989,566 deals with stable solutions containing calcium gluconate 4–25% and 0.5–25% of calcium salts of monocarboxylic acids derived from polyaldoses such as calcium lactobionate—A. STOLL and E. BURCKHARDT (to Chemische Fabrik vorm. Sandoz) Jan. 29, 1935.

ω -Chloroacetylpyrocatechol—Some Thiazol Derivatives of The author condensed, 3,4-dihydroxy- ω -chloroacetophenone in acetone with thiourea or derivatives of thiourea, obtaining the corresponding thiazol derivatives. The following were prepared: 2-Amino derivative, hydrochloride, m. p. 235° to 236°, acetyl derivative, m. p. 268°. 2-Allyl amino derivative, m. p. 208° to 209°, hydrochloride, m. p. 213°. 2-Phenyl-imino, 3-phenyl derivative, m. p. 251° to 252°. The 2-ortho tolyl-imino, 3-ortho tolyl derivative, m. p. 130°, hydrochloride, m. p. 185°. The analogous meta-derivative, m. p. 227° to 228°, hydrochloride, 226° to 227°. The analogous para-methyl derivative, m. p. 280° to 281°, hydrochloride, m. p. 170°. The analogous 2 para hydroxy-phenyl imino, -3 para-hydroxy phenyl derivative, hydrochloride m. p. 198° to 200°. The proof of structure was established by analyses, by a negative reaction for the CO group with phenyl hydrazine and a negative Grote reaction. The parent thiazol derivative was synthesized by condensing potassium thiocyanate with the ω -chloroacetylpyrocatechol. The corresponding derivative of acetophenone differed from the thiocyanate prepared from acetophenone by Dyckerhoff—ZENICHI HORII *J. Pharm. Soc. Japan*, 55 (1935), 6–8. (R. E. K.)

Chlorinated and Brominated Hydroxybiphenyls A halogenated hydroxybiphenyl is prepared by the reaction of free halogen with hydroxybiphenyl in a solvent such as carbon disulphide or glacial acetic acid. Keeping the temperature below 20° facilitates the production of a monohalo derivative such as 2-hydroxy 5-bromobiphenyl or 2-hydroxy 5-chlorobiphenyl. Some 3-halo- and 3,5-dihalo-derivatives are also formed. The products possess strong bactericidal action—W. G. CHRISTIANSEN, E. MONESS and S. E. HARRIS (to E. R. Squibb and Sons) U. S. Pat. 1,989,081, Jan. 29, 1935.

Derris Resin—Constituents of A dimorphic substance, m. p. 189° and 192–194°, is isolated in very small yield from a derris resin which contains only a small amount of rotenone. The substance probably has the formula $C_{24}H_{18}O_7$, it differs from the isomeric tephrosin in being phenolic and in not readily losing the elements of water, and from the isomeric toxicarol in being colorless, it has insecticidal properties. Toxicarol does not exist as such in derris resin, evidence shows that only small quantities of dl deguelin or tephrosin exist as such in derris resin—R. S. CAHN and J. J. BOAM *J. Soc. Chem. Ind.*, 54 (1935) 42T. (E. G. V.)

1,2-Dimethyl-Naphthalene—Isolation of, from Coal Tar So far four dimethyl naphthalenes were known, that is 1,6, 2,6, 2,7 and 2,3 dimethyl-naphthalene. All 4 isomers were easily separated with the exception of 1,6 dimethyl-naphthalene which requires special care in being crystallized out from sulphonic acid. The discovery of the 5th isomer was that of 1,2 dimethyl naphthalene. The separation and washing of the crystals were done with the aid of picrates. The material used was tar oil, the process of extraction employed was fractional distillation. Especially hard was the separation of 1,2 dimethyl naphthalene from the isomer 2,3 dimethyl naphthalene, which has the same boiling point, but higher melting point. The formation of ace

naphene during the fractional distillation, was easily removed using dilute sulphuric acid. The distillate was then mixed with picric acid and alcohol, and after several recrystallization processes beautiful picrate crystals separated out. The fractional distillation was done at a temperature of 266–270° and the yield was that of 23% of 1,2 dimethyl naphthalene in heavy oil coal tar. To prove the constitution of 1,2 dimethyl naphthalene the method given by F. Mayer and A. Sieglitz was used. Its properties such as boiling point, refractive index, Sp. Gr. were identical with hydrocarbons obtained from coal tar, even the picrate and its mixture showed the same melting point. The splitting up with chromic acid to obtain α chinons with potassium permanganate resulted in 1,2,3,4 benzotetracarboxylic acid and after the oxidation of the hydrocarbons with nitric acid naphthalene-dicarboxylic acid was obtained. The dimethyl ester of this acid corresponds with the synthetic product. The discovery of 1,2 dimethyl-naphthalene in coal tar is important because (coal tar) hydrocarbons give us one of the few true oils, and because there are only 4 true liquid hydrocarbons obtained from it, namely α methyl-, 1,6, 1,2 dimethyl naphthalene and *m* methyl diphenyl —O. KRUBER and W. SCHADE. *Ber.*, 68 (1935), 11 (G. B.)

Glycerin—Regeneration of, in Production of Glycerophosphates. In the production of glycerophosphates the free glycerin is recovered with alcohol in which it is soluble while sodium glycerophosphate, for example is not. In this way 25% of the glycerin is recovered. The product contains but traces of sodium chloride, and a little sodium glycerophosphate, and thus can be esterified without further purification with sodium monophosphate —N. O. BOLZ and R. W. MURACHWER. *Chimiko farmazew Tscheskej Promyslennost* (1934), 25–26. *Pharmaz. Fabrik Im Karpow*, through *Chem. Zentr.*, 106 (1935), 594 (G. B.)

β -Iodoxyhydroxynaphthalenedisulphonic Acids. The compounds are slightly colored in the dry state, soluble in water and suitable for therapeutic use and for use as intermediates for the manufacture of other compounds. They are obtained by heating in an aqueous medium the diazonium iodides of beta diazoxyhydroxynaphthalenedisulphonic acids —A. STOLL, A. BINKERT and W. KUSSMAUL (to Chemische Fabrik vorm. Sandoz). U. S. Pat. 1,988,222 Jan. 15 1935.

Lactic Acid—Physical Characters of, in Course of Aging. Of the following physical constants studied: density, viscosity, surface tension, conductivity and p_H values, it is the surface tension of a particular acid which permits the determination of the degree of concentration, purity and age. Freshly prepared lactic acid of the French Codex has a S. T. of 46 dynes/cm —W. KOPACZEWSKI. *Bull. sci. pharmacol.* 42 (1935) 87 (C. T. I.)

Penicillium Charlesi—Molecular Constitution of, Metabolic Acids of. A series of acids produced from glucose by *Penicillium Charlesi* G. Smith is shown from a study of the products of hydrolysis, bromination, reduction and reactions with dinitrophenylhydrazine and diazo methane to have the following structures: γ -methyltetronic acid $C_5H_8O_5$, carolic acid $C_9H_{10}O_6$ in non aqueous solvents, carolic acid $C_9H_{10}O_6 + H_2O$ in aqueous solution, carolinic acid $C_9H_{10}O_6$, carlic acid $C_{10}H_{10}O_6$ in non aqueous solvents, carlic acid $C_{10}H_{10}O_6 + H_2O$ in aqueous solution, carlosic acid $C_{10}H_{12}O_6$. Carolic, carolinic, carlic, carlosic and synthetic α acetyl-tetronic acids all contain the α keto substituted tetronic acid ring. On reduction with palladium-charcoal hydrogen the carbonyl group of the side chain attached to the α -carbon is in all cases reduced to CH_2 . Synthetic α acetyl-tetronic acid contains the same nucleus as the metabolic acids and gives a complete analogy with these acids in respect to the series of reactions described above. The metabolic products are derivatives of γ -methyl and γ carboxymethyl tetronic acids —P. W. CLUTTERBUCK, H. RAISTRICK and F. REUTER. *J. Soc. Chem. Ind.*, 54 (1935), 171 (E. G. V.)

Organic Arsenic Compounds. Examples are given of the preparation of compounds having the general formula $HO-CH_2-CO-NH-Ar-X$ where X represents $-AsO_3H$ or $-As=O$. Y stands for H or lower alkyl groups and Ar represents a phenyl group or a phenyl group which has an hydroxy, or a lower alkyl group, or a lower alkoxy or a halogen substituted for one hydrogen. The products are claimed to be nontoxic —K. STREITWOLF, A. FEHRLE and H. OESTERLIN (to Winthrop Chemical Co.). U. S. Pat. 1,988,758, Jan. 22 1935.

Potassium Stannic Pyrocatecholdisulphonate and Other Complex Metal Compounds. Complex metal salts of polyhydroxybenzene compounds containing at least two hydroxyl groups in ortho position and at least one acid group capable of forming a salt of an alkali metal, and a metal capable of being oxidized. Various oxidizing agents may be used, e. g. hydrogen peroxide, magnesium peroxide, sodium persulphate etc. The oxidation is generally carried out in solution. The solutions containing the products are evaporated or the new compounds are precipitated by

adding an organic solvent, e. g., methyl alcohol. In certain cases the compounds may be oxidized in the solid state. The new compounds are generally colored powders, soluble in water and generally are less toxic than the unoxidized compounds. Several examples with procedures are given — H. SCHMIDT (to Wintthrop Chemical Co.) U. S. Pat. 1,988,575, Jan. 22, 1935.

BIOCHEMISTRY

Anterior Pituitary—Clinical Manifestations of Dysfunction of A review of the more important literature relating to laboratory and clinical symptomatology with deficiency or absence of one or another of the several hormones elaborated by the anterior lobe of the pituitary gland — H. M. EVANS *J. Am. Med. Assoc.*, 104 (1935), 464 (M. R. T.)

Anterior Pituitary—General Physiology of A discussion and review of the literature dealing with the physiological role of the several hormones of the anterior pituitary — P. E. SMITH *J. Am. Med. Assoc.*, 104 (1935), 548 (M. R. T.)

Blood Iron—Methods for Determining Comparison of Wet and Dry Ashing. Wong's method was changed in so far as the blood mixture with sulphuric acid and persulphate was heated to 80° for 10 minutes. For the dry method, the blood was evaporated on a hot plate, ignited for 8 hours and, after addition of one cc. nitric acid, dried again. The solution in 6*N* hydrochloric acid was centrifuged after addition of ammonium hydroxide and the liquid was used for copper determination by McFarlane's method. The precipitate was dissolved in sulphuric acid, oxidized with persulphate and used for colorimetric estimation with potassium thiocyanate. The deviation between both methods is less than 1%. — A. A. FABIAN, A. SACHS and V. E. LEVINE *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 662 (A. E. M.)

Calcium Phosphate—Colloidal, of Blood Serum and Calcium Partition in Serum The maximum of protein bound non diffusible calcium in beef serum is 14 mg. % with a concentration of 7.2% protein. Colloidal calcium phosphate found in blood serum has the composition of the tertiary salt, and the equilibrium between protein bound and ionized calcium conforms to the mass law. — D. M. GREENBERG, C. E. LARSON and E. V. TUFTS *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 647 (A. E. M.)

Carotenoids of Butter A number of ordinary and colostrum butter carotenes have now been submitted to a detailed chromatographic analysis with spectroscopic control. Using either alumina or calcium hydroxide as adsorbents, it has been found that the pigment can be separated into two fractions having the properties of α - and β -carotene, respectively, the relative amounts of each varying considerably in different samples. β -Carotene is commonly present in 2–3 times the amount of α isomeride but in some cases the latter predominates. In addition to these two isomers the yellow pigments of butter, petrol-phasic to 90 per cent methyl alcohol, usually contain minute amounts of other carotenoids, the adsorption properties and spectroscopic criteria of which indicate the presence of kryptoxanthin and lycopene. Thus in addition to vitamin-A, butter contains two, and sometimes three other compounds exhibiting growth-promoting activity. — A. E. GILLAM and I. M. HEILBRON *J. Soc. Chem. Ind.*, 54 (1935), 173 (E. G. V.)

6,7-Dimethyl-9-L-arabo-flavin — Lacto-flavin in *N/20*. Sodium hydroxide is levorotatory. The specific rotation $[\alpha]_D^{20} = -115^\circ$ is the same of substances found in milk, liver and lucern. Synthetic 6,7-dimethyl-9-L-arabo-flavin which is active because of vitamin B₂ content, is also levorotatory. The synthetic tetraacetyl 6,7-dimethyl-9-L-arabo-flavin resembles natural tetraacetyl-lacto-flavin. Specific rotation is also the same. L-Arabinose (synthetic) is dextrorotatory, the levorotatory rotation of flavin is due to the formation of *l*-arabinamides which are little levorotatory. In order to better understand the specific rotation of natural vitamins a study was made of the position of hydroxyl groups on other synthetic sugars such as *l*-arabinose, *d*-xylose, *l*-xylose and *d*-ribose. H. Theorell obtained protein substances from the yellow ferment which are not identical with lacto-flavin. By denaturizing the yellow ferment he obtained 1 molecule of phosphoric acid. The activity of lacto-flavin in the ferment is due to lacto-flavin phosphoric acid and not to lacto-flavin alone. Former experiments with animals, proved the presence of vitamins to contain proteins, now the activity seems to be due to phosphoric acid also. Vitamin + Phosphoric Acid + Protein = Ferment. According to H. Theorell, the activity of the yellow ferment is due to the replacement of purine with 6,7-dimethyl alloxazin, which makes it (yellow ferment) a nucleotid 6,7-Dimethyl-iso alloxazin = 6,7-dimethyl flavin. There is a great difference between alloxazins and flavins but little difference between synthetic flavins and yellow ferment. The lack

of hydroxyl-groups makes the esterification of 6,7-dimethyl-9n amyl flavin with phosphoric acid impossible, hence its lack of vitamin B₂ activity —R KUHN and F WEYGAND *Ber*, 68 (1935), 166 (G B)

Dimethyl-Flavin—6,7-Dimethyl-Flavin-9-Acetic Acid The synthesis of flavin carboxylic acid is not important with respect to the substance, but is important from a biological standpoint. The carboxyl group attaches itself to the benzene ring through oxidation of lumi lacto flavin with potassium permanganate, it is suspected that the formation of carboxylic acid in the system from vitamin B₂, is produced through the oxidation of the methyl groups in the chain. There is present a carboxylic acid whose group is attached to the 9th position of the chain. 1,2-Dimethyl-4 nitro-5 amino benzol was condensed with acetic acid bromide into 1,2 dimethyl-4 nitro 5 anilin-acetic acid. The reduction to amino acid with alloxan was not very successful. With sodium stannate the reduction is hastened, and 6,7-dimethyl flavin-9-acetic acid obtained. The methyl ester melts at 293°. The free carboxylic acid is soluble in water but not in chloroform. 6,7 Dimethyl flavin 9 acetic acid is susceptible to light in neutral and slight acid solution. In alkali solution it is stable to light. This proves that the carboxylic acid is not a by-product in the photo chemical reaction from lumi lacto flavin to lacto flavin. The water-soluble 6,7-dimethyl flavin-9 acetic acid shows no nourishing effect on rats, deficient in vitamin B₂. The same is true of the glycerin ester. The lacto flavins are active biologically, soluble in water, insoluble in chloroform, the residual tetraoxy-butyl plays an important part in the constitution of vitamins —R KUHN and H RUDY *Ber*, 68 (1935), 300 (G B)

Ergosterol—Attempt to Ketonize Since an earlier investigation had concluded that activation of ergosterol by ultraviolet light is due to a chemical isomerization and because keto enol isomerism is theoretically possible, ergosterol was subjected to a reaction with hydroxylamine under conditions which were known to give an almost quantitative yield in the formation of the oxime of cyclohexanone. Ergosterol was recovered unchanged from the reaction material. Details of experimental work are reported —E MONESS and W G CHRISTIANSEN *J Am Pharm Assoc* 24 (1935), 115 (Z M C)

Gonadotropic Factors—Interrelationships among Urinary, Pituitary and Placental A review, with discussion, of available evidence emphasizing similarities and differences among the gonadotropic factors demonstrable in the urine, pituitary and placenta, and the physiological interrelationships made apparent by the existing evidence —J B COLLIP *J Am Med Assoc*, 104 (1935) 556 (M R T)

Gonadotropic Hormones—Hypophyseal A review of published evidence showing that the gonadotropic substance from the hypophysis is composed of two principles, one a gametokinetic (follicle stimulating) hormone the other a "luteinizer" causing luteinization of the ovary and presumably acting also on the interstitial tissue of the testes —P E SMITH *J Am Med Assoc* 104 (1935), 553 (M R T)

Lacto-flavin (Vitamin B₂)—Isolation of, from Hay Research proved that flavin is a constant component of all green leaves, as is chlorophyll. Its properties are compared to that of a ferment-like substance. Whether it is part of the chloroplasts or chlorophyll or whether it is present in the cell content, or whether it is assimilated during the formation of carbonic acid or during the respiration process, that is unknown, but its presence is there as such. To answer these and other questions the isolation of flavin from green plants was undertaken. It was found that milk and liver were rich in lacto flavin (vitamin B₂), but the fact to be proven was whether the vitamin B₂ reached the liver and mammary glands of animals unchanged or whether it undergoes changes the same as the carotene in plants into vitamin A. Hay meal was chosen because it is used in food for cows and also because cows' milk is rich in vitamin B₂. One hundred and three Kg of hay-meal was boiled with 1480 liters of water and after extraction, 50-70 mg of lacto flavin in the form of tetraacetyl was obtained. The crystals obtained showed the same general structure, optical rotation, absorption spectrum and constructive metabolism properties as the tetraacetyl lacto-flavin found in milk. It was proven also that lacto flavin is a plant coloring material (pigment) and that it passes from the animal through his liver and into its milk undergoing no changes. The increase in the amount of vitamin B₂ in green leaves is possibly due to respiration in plants during the formation of carbonic acid or liberation of carbon dioxide. One Kg of fresh green leaves contains 0.0005 Gm vitamin B₂ and 2.0 Gm chlorophyll. The relation of the coloring material is flavin to chlorophyll = 1:2000. Not much stress is laid on this theory that is, the

increase in amount of vitamin B during the assimilation of carbonic acid—R KUHN and H KALTSCHMITT *Ber*, 68 (1935), 128 (G B)

Lumi-lactoflavin—Natural and Synthetic Synthetic 6,7,9 trimethyl flavin obtained from formic acid in the form of yellow needles, differs from dye products ($C_{13}H_{12}N_4O_2$) of natural origin as follows 1 On hydrolysis, oxy carbonic acid ($C_{12}H_{12}N_2O_3$) formed and not 6,7-dimethyl alloxazin or the compound $C_8H_{10}N_2O_2$ 2 The coloring action of the synthetic material is 7% greater than in the natural products Synthetic 9 methyl, 6, 9 dimethyl and 6,7,9 trimethyl flavin show no melting point but decompose and carbonize at 300° , natural lumino flavin crystals melt at 330° Such deviations depend, in the natural lacto flavin, on the purification over silver salts and recrystallization from acetic acid These preparations are composed of a mixture of methyl-imid free coloring substance (α lumi-lactoflavin) and methyl imid in combination (β -lumi-lactoflavin) Lumi lactoflavin is not a flavin (iso alloxazin) but 6,7-dimethyl alloxazin β -Lumi lactoflavin is identical with 6,7,9 trimethyl flavin Lumi-lactoflavin $C_{13}H_{12}N_4O_2$ was synthesized for the first time in a pure state The separation of a mixture of 6,7,9-trimethyl flavin from 6,7 dimethyl alloxazin is difficult because of close resemblance of their properties

6,7,9-Trimethyl-flavin

6,7-Dimethyl alloxazin

The origin of 6,7-dimethyl-alloxazins in natural lumi-lactoflavin preparation is not clearly understood Further investigation led us to consider the formation of other constituents during the preparation of "whey" from milk—R KUHN, H RUDY and K RENIEMUND *Ber*, 68 (1935), 170 (G B)

Luteal Hormone The author gives a complete review of the literature and discusses the method of Allen for preparing pure crystalline luteal hormone substance He modifies the technique as follows Extract with 70% alcohol, using 3 Kg of alcohol per Kg of tissue The residue is then extracted with 2 portions of absolute alcohol, and the extract is dried *in vacuo* This residue is then extracted with several portions of ether, which after distillation of the ether leaves an oily residue Acetone is then added to precipitate the fatty insoluble materials The liquid is then distilled in vacuum and the oily residue is taken up in methyl alcohol On cooling, most of the oil containing a little active material settles out This residue is extremely difficult to purify The alcoholic solution is diluted with water, then cooled in an ice salt mixture for several hours and then filtered This is repeated until no further precipitation occurs, thus eliminating cholesterol and neutral fats The alcoholic filtrate is mixed with ethyl alcohol, and shaken out with petroleum benzine The luteal substance goes into the petroleum benzine which is removed *in vacuo* The oil is then distilled *in vacuo*, and the fraction obtained between 140 – 160° is richest in hormone After a while, crystals separate The crystals are washed with absolute alcohol and may be recrystallized from ethyl acetate The author believes the product is the same substance as that isolated by Hartmann and Wettstein—D VAN STOLK and M H PENAU *J pharm chim*, 21 (1935), 193 (M M Z)

Pituitary—Separation of Anterior Thyreotropic Hormone of The thyreotropic hormone (I) can be separated from the gonadotropic (II) in the pituitary extracts by precipitating with benzyl alcohol the isoelectric soluble fraction obtained in the isoelectric precipitation at pH 4.2 of crude pyridine extract containing I and II I is precipitated quantitatively When preparations containing I and II were heated, no deleterious effects were observed at $60^\circ C$, at 70° , both I and II were seriously impaired, at 80° , I was completely inactivated and II nearly so, at 100° , both were completely destroyed Excessive doses of placental extract, and urine and blood serum of pregnancy had no effect on the thyroid I in a dosage equivalent to 1 Gm of sheep pituitary powder per week, produced the greatest stimulation of guinea pig thyroid in one week By the end of the third week of treatment, the thyroid had practically returned to normal It was previously re

ported that the thyroid could not maintain a hyperfunctioning capacity in the presence of chronic hyperpituitarism—R O GREEP *Am J Physiol*, 110 (1935), through *Squibb Abstract Bull* 8 (1935) A 307

Pituitary—Chromatophorotropic Principles of Pars Intermedia of A review of the literature with emphasis on the presentation of evidence proving the existence of a specialized pigment influencing hormone, called 'intermedin,' elaborated by the pars intermedia of the pituitary—B ZONDEK *J Am Med Assoc*, 104 (1935), 637 (M R T)

Pituitary—Lactogenic Factor of A review of pertinent literature dealing with the factor, elaborated by the pituitary gland, which is essential to lactogenesis—OSCAR RIDDLE *J Am Med Assoc*, 104 (1935) 636 (M R T)

Plasma Fibrin—New Method of Determining One cc of oxalated plasma is diluted 25 to 30 times with normal saline solution To this 0.3 cc of a 1:5000 dilution of dried tiger snake venom in saline is added The fibrin clot is washed thoroughly on a filter and dried at 37° or 110° S ROSENFELD and A S WIENER *Proc Soc Exptl Biol Med*, 32 (1935) 788 (A E M)

Posterior Pituitary A review of the more important pharmacological and bio chemical literature dealing with the acutely potent hormones existing in the posterior lobe of the pituitary gland—E M K GEILING *J Am Med Assoc* 104 (1935) 738 (M R T)

Thrombin—New Method of Preparation Fresh fibrin from calves was washed free of hemoglobin and extracted with ether The dried material was extracted with 8% sodium chloride solution and the filtered extract dialyzed first against water, then against a Sørensen buffer mixture of pH 7.38, finally again against water The solution was dried with an electric fan The potency of the dry preparation is stable—A C ROBERTS *Proc Soc Exptl Biol Med* 32 (1935) 606 (A E M)

Van Der Bergh Reaction of Bilirubin—Variations in Xanthochromic Cerebrospinal Fluid A prompt reaction is obtained when the concentration of the pigment is above 0.3 mg % and at low protein concentration Increase of proteins or low pigment content produce delayed reactions It is supposed that delayed reactions in blood are brought about by the same conditions—S L VAUGHAN and R S HUBBARD *Proc Soc Exptl Biol Med*, 32 (1935), 618 (A E M)

Vitamin-A Active Substances in Egg Yolk The presence of carotene in egg yolk was confirmed, removing carotene from the total pigments by partition between petroleum ether and 90 per cent methyl alcohol Analysis reveals kryptoxanthin to be associated with the carotene the content of the former was raised to 0.2 mg per 100 Gm of yolk by feeding hens on a rich maize diet—A E GILLAM and I M HEILBRON *J Soc Chem Ind* 54 (1935) 173 (E G V)

Vitamins B—Experimental Investigations on, in Their Relations to Glucides, Proteins and Lipids of Diet After a critical review of recent work on vitamins B, extensive experiments carried out on pigeons are described, and the results discussed *Conclusions* The B group of vitamins comprises 3 distinct vitamins B₁ or antineuritic B or antidermatitic (antipellagrous) and B₂ or antidenutritional which exert complementary and interdependent actions on the animal or organism Absence of vitamins B in presence of glucides, proteins or lipids produced attacks of polyneuritis typical of avitaminosis B, rapidly followed by death, preventive or curative addition of brewers yeast ensured the maintenance or recovery of health in all the birds experimented upon provided the diet itself was properly balanced The specific nature of the glucides, proteins and lipids exert considerable influence on the rate of evolution of total avitaminosis B and also on the dose of vitamins B required to maintain the birds in a satisfactory physiological condition The individual effects of simple compounds can be very considerably attenuated when they are combined in more complex molecules e g levulose in sucrose or inulin, polypeptides bound in natural proteins (and liberated in peptones) The digestibility (rate of intestinal assimilation) of glucides proteins and lipids control to a considerable extent the requirements of vitamins B necessary to ensure utilization of the diet e g, the vitamins B requirements are considerably reduced with diets comprising largely potato starch, beef muscle and cod liver oil while they are especially high with diets based on glucose or sucrose peptones or olive oil With substantially equal digestibility, the vitamins B requirements seem greater in the case of glucides The presence in the diet of large proportions of certain substances (e g galactose lactose castor oil and to some extent muscle peptone) unbalances the diet so that its equilibrium cannot be restored with doses of brewers yeast which are sufficient for a normal diet In rebalancing a diet contain

ing such substances, the addition of lipids or of unpeptonized proteins apparently plays an important part, these lipids and proteins apparently exercising a reserve action toward the vitamins B supplied by the diet or present in the organism—**RAOUL LECOQ** *Bull soc sci hyg aliment*, 22 (1934), 278-331 (A P C)

Vitamin B₁, Crystalline—Studies of II Elementary Composition and Ultraviolet Absorption The authors, after careful analysis of the hydrochloride of vitamin B₁ which had been crystallized several times from 85% alcohol and dried over calcium chloride in partial vacuum at 55°, suggest C₁H₁₆ON₂S₂HCl as the formula. They also found ultraviolet absorption to occur in two bands at 235 mμ and 276 mμ, respectively—**O. WINTERSTEINER, R. WILLIAMS and A. E. RUEHLE** *J Am Chem Soc*, 57 (1935), 517 (E B S)

Vitamin B₁, Crystalline—Studies of Cleavage of Vitamin with Sulphite The vitamin was treated with sodium sulphite solution containing sufficient excess of sulphurous acid to bring the pH to 4.8-5.0 and having a sulphite content of 2.6N. Cleavage was completed at room temperature in twenty four to forty eight hours and at steam bath temperature in one hour or less. A sparingly soluble acidic product having the composition C₆H₇N₂SO₃ and a chloroform soluble base having the composition C₆H₇NSO were obtained—**R. R. WILLIAMS, R. E. WATERMAN, J. C. KERESZTESY and E. R. BUCHMAN** *J Am Chem Soc*, 57 (1935), 536 (E B S)

Vitamin B₂—Condition of, in Cows' Milk Fresh cows' milk containing lacto flavin (Vitamin B₂) is about 90% dialyzable. The dialyzing test did not determine whether the coloring material is combined with protein in milk. The test was made to determine whether the vitamin is present in the free state or is esterified with phosphoric acid. The behavior in the electrical field of lacto-flavin and lacto flavin-phosphoric acid was easily told apart. The milky suspension has a pH of 7.2 and travels to the anode, in contrast to the yellow green fluorescent coloring material which does not ionize. To prove this test, skimmed milk, the yellow green fluorescent crystals of which did not ionize, was used. This experiment proved that the coloring material from the "whey" is not identical with the properties of the "yellow ferment," and during the process of isolating vitamin B from milk no phosphoric acid ester of the vitamin was detected. Although lacto flavin, a plant coloring material is, naturally found as such in plants, the name lacto flavin is more properly established because it was crystallized (C₁₇H₁₀N₄O₆) first from milk and also because it is found there free that is, not as an ester—**R. KUHN and H. KALTSCHMITT** *Ber*, 68 (1935), 386 (G B)

Vitamin B₂-Phosphoric Acid—Synthesis of This test was to determine whether, the "yellow ferment," the color component of flavin is in any way connected with phosphoric acid. The color component of the ferment contains a vitamin B which is important in metabolism. The experiment was to prove whether the vitamin B is found in its free dialyzable form, as phosphoric acid ester, or whether there is a difference in metabolism between flavin and phosphoric acid flavin. There is a possibility that synthetic flavin might react in the system to be esterified with phosphoric acid. To answer this and other questions, the problem of lacto-flavin-phosphoric acid has been taken up. From the lacto flavin esters only one tetraacetyl combination is known. Obtaining the phosphoric acid ester was accomplished with the use of phosphoroylchloride in pyridine. After washing with silver and sodium salts the formation of lacto flavin phosphoric acid crystal aggregates separated out. The correct position of phosphoric acid in the structural formula is unknown, but its molecular formula is C₁₇H₁₂N₄PO₆. The phosphoric acid ester of lacto flavin is the same in color and fluorescence as that of lacto flavin, the pH (7.17) of the synthetic vitamin B₂ phosphoric acid is the same as that of the "yellow ferment" but differs from that of lacto flavin whose pH ranges from pH 3 to pH 9—**R. KUHN and H. RUDY** *Ber*, 68 (1935), 383 (G B)

Vitamin D—Transformation of Highly Potent Physiological Products with Ultraviolet Rays Irradiation of the known ester of *m* dinitrobenzoic acid or its derivatives converts the mixed ester to the ester which is physiologically active. It separates out in crystalline form, which can be purified through recrystallization, saponified and the active principle isolated from the saponifiable mixture through extractions. Vitamin D in heptane is first irradiated with magnesium light, dried, dissolved in pyridine, and esterified with dinitrobenzoylchloride. It is washed with water acidified with hydrochloric acid then with sodium carbonate solution and finally collected in ice sodium chloride. The ester crystallizes out, and is purified by recrystallization from acetone. After saponifying it with methyl alcohol and potassium hydroxide, an organic substance,

$C_{25}H_{44}O$, is obtained—O LINSERT D R P 603088 KI 12 p from 6/11/1932 rendered 22/9/1934, through *Chem Zentr*, 106 (1935), 110 (G B)

ANALYTICAL

Acimo—Analysis of Acimo consists of 55 Gm of a powder containing magnesium carbonate 25 Gm, bismuth carbonate 1 Gm and sodium bicarbonate 14 Gm. The author describes methods of analysis. Sodium is determined by igniting 2 Gm of the powder for 30 minutes, cooling in a calcium oxide desiccator, taking up in CO_2 free water, filtering, adding 4 cc of dilute H_2SO_4 to the filtrate, evaporating to dryness, igniting and weighing the sodium as sodium sulphate. 142 mg of sodium sulphate is equivalent to 168 mg of sodium bicarbonate. Bismuth is determined by dissolving the water-insoluble residue obtained in the sodium determination in dilute HCl and precipitating with H_2S after which the precipitate is filtered off on an ashless filter paper, ashed, and after cooling treated with HNO_3 , heated and again treated with HNO_3 and finally heated to red heat, the bismuth being weighed as Bi_2O_3 . 42.5–45 mg of Bi_2O_3 represents 50 mg of bismuth carbonate. Magnesium is determined by boiling the filtrate from the bismuth determination until all the H S has evolved. The precipitated sulphur is filtered out and the magnesium is precipitated with sodium phosphate, the resulting magnesium pyrophosphate being ignited and weighed. 1.3815–1.485 Gm magnesium pyrophosphate is equivalent to 1.250 Gm magnesium carbonate. Purity requirements are given as follows. The powder must be free from chloride, sulphate and arsenic, and 2 cc of a 500 mg solution in 10 cc dilute H_2SO_4 must give no stronger nitrate reaction than that of 2 cc of a solution of 3.26 mg of KNO_3 in 1 liter. The analysis of "Bismuthated Magnesium" may be carried out in the same way—H J VAN GIFFEN *Pharm Weekblad*, 72 (1935), 189 (E H W)

Adhesive Plasters—Lesions Produced by and Method of Determining Adhesive Power Constituents of adhesive plasters, which may cause skin affections, are rosin, turpentine, lead and sulphur chloride. When piece of plaster is applied to a test object, it must resist separation there from evenly throughout the entire adhesive surface but the plaster mixture must not separate from its ribbon base on either side. The adhesive power can be estimated by pressing a 50-cm square piece vertically against a smooth surface (glass) and placing a weight at the upper end sufficient to pull it slowly off. The time required and the weight used give a means for comparison. Resistance against traction is estimated by sticking a 5-cm square piece against a smooth surface and determining the weight which will pull it off when applied to the lower end—FRANCISCO N COSENTINO *Semana med*, Buenos Aires, 42 (1935), 688 (A E M)

Bromides—Determination of Small Quantities of, in Sodium Chloride The reagents used are: An aqueous Cl solution (about 0.24 mg Cl per cc) and a 0.2% solution of fuchsine (pararosaniline hydrochloride) in H_2O . Determine the number of drops of Cl water required to decolorize one drop of the fuchsine solution in 10 cc H_2O . This should require 6–8 drops. Dissolve 3 Gm NaCl in 10 cc H_2O , add 10 cc H_2O containing a drop of fuchsine solution and add twice the number of drops of Cl water, as determined before. A violet-blue color indicates the presence of Br. Large quantities cause a violet precipitate. The reaction is sensitive to 0.1 mg KBr—R CASARES LÓPEZ *La Farm Mod*, 46 (1935), 55 (A E M)

Calcium Glycerophosphate—Analysis of The different forms of calcium glycerophosphate are shown and methods of analysis are reviewed. The results obtained on analysis of three commercial samples are given—E DELVAUX *J pharm Belg*, 17 (1935) 167, 183 (S W G)

Calcium Hypochlorite—Value of, as Volumetric Oxidizing Agent—Stability and Standardization of Solution of Determination of Ammonia. Solutions of hypochlorite have found little application in volumetric analysis since in general they are unstable. It was found that Matheson Alkali Works' "H T H" calcium hypochlorite yielded solutions which were quite stable. By adding an excess of bromide to the sample to be titrated the hypochlorite behaves as hypobromite. The solution may be standardized against arsenic trioxide using Bordeaux as indicator, in acid or weakly alkaline solution. For the determination of ammonia (from 0.5 to 20 mg) the mixture is allowed to stand 3 to 5 minutes with a slight excess of hypochlorite then treated with potassium iodide and acid and back-titrated with standard thiosulphate—I M KOLTHOFF and V A STENGER *Ind Eng Chem, Anal Ed*, 7 (1935) 79 (E G V)

Chlorate Ion—Rapid Test for Qualitative and Approximately Quantitative Test Especially Suitable for Work with Plant Extracts. A method has been devised for the detection of small

amounts of chlorate which is especially suitable for work with plant extracts. Ammonium thiocyanate in test paper is oxidized by the chlorate compound with the production of yellow oxidation products of thiocyanic acid. The yellow coloration can be made roughly quantitative as well as qualitative by comparing the color of the unknown against the color of standard test papers. Under the conditions of the test the oxidation products consist largely of canarine and pseudothiocyanic acid, with small amounts of hydropseudothiocyanic acid and isopertthiocyanic acid. The sensitivity of the test and the influence of other constituents on the accuracy of the method are also discussed. Halogens, bromate and iodate, hyposulphites, persulphates, peroxides and cupric salts give somewhat the same coloration of the thiocyanate test paper as the chlorates—H R ORFORD *Ind Eng Chem, Anal Ed*, 7 (1935), 93 (E G V)

Cholesterol—Quantitative Determination of Free, and as Ester without the Use of Digitonin. One cc of serum is extracted with alcohol ether by Bloor's method, dried and dissolved in anhydrous chloroform. Two standards are prepared one with cholesterol oleate equivalent to 16 mg cholesterol, the other with 16 Gm free cholesterol in 10 cc chloroform. One cc of a mixture of 25 volumes of sulphuric acid with 1000 acetic acid cooled to 0° is added. Colorimetric reading is made after 50 minutes standing at 0–2°. The solutions are compared with a 0.0025% solution of naphthyl green B. The color corresponds to the esters, while the free cholesterol gives only a very faint color which must be considered in the calculation of results. After keeping the solutions for 40 minutes at 38°, a second reading is obtained corresponding to the total cholesterol—J G REINHOLD *Proc Soc Exptl Biol Med*, 32 (1935), 614 (A E M)

Cinchona Bark Preparations—Production and Tests of. A comparative critical investigation of the useful methods for determining the alkaloid content of the cinchona preparations described in dispensaries and pharmacopœias. The report discusses the determination of alkaloids of the bark of *Cinchona succirubra* with particular reference to the fineness of the powder used for extraction and the moisture content of the powder. The uses of the individual cinchona preparations and their alkaloids are also considered. For details, the original article must be consulted—K MATOLCSI *Magyar Gyógyszerstudományi Társaság Értesítője* 10 (1934), 488–524, through *Chem Zentr*, 106 (1935), 595 (G B)

Citrine Ointment—Assay of. Following a brief historical introduction, the composition of the ointment is discussed. It is essentially mercuric nitrate solution mixed with elaidin containing basic oxides of mercury, mercuric oleate, palmitate, stearate and elaidate. In the experimental work, most of the suggested methods for ointments of mercury compounds were rejected because of their complexity and the time required. Strickland's method which treats the ointment with nitric acid and titrates the mercuric nitrate solution with potassium thiocyanate was tried. Results were low and variable, probably because the long time required to break down organic matter in the ointment permitted volatilization of mercury. A stronger oxidizing mixture seemed necessary and perchloric acid (Sp Gr 1.615), 1 part, fuming nitric acid (Sp Gr 1.49), 2 parts, and distilled water 2 parts was found satisfactory. The following method was developed: "Place about 5 Gm of the ointment, accurately weighed, in a flask containing 50 cc of the above acid mixture and reflux until a clear solution is obtained and the brown fumes are no longer distinguishable. Dilute the solution with about 20 cc of distilled water and pass it through a filter paper into a 100-cc volumetric flask. Wash the funnel with sufficient distilled water to bring the volume up to 100 cc. Take a 20 cc aliquot of this solution, titrating it with N/10 potassium thiocyanate solution, using ferric alum as the indicator, until a permanent reddish brown color is obtained. The condenser and flask used should be fitted with ground glass connections in order to avoid contamination and error which might occur from the action of the acid mixture upon either cork or rubber stoppers." Details of experimental work are reported and results are tabulated—T G WRIGHT *J Am Pharm Assoc*, 24 (1935), 102 (Z M C)

Coffees, Decaffeinated—Caffeine Content and Value of, in Nutrition. The method used by G and L for the determination of small amounts of caffeine in decaffeinated coffee involved the following procedure. 25 Gm of finely ground coffee are placed in a flask and moistened with 20 cc dilute ammonium hydroxide (1 + 3) and then shaken intermittently for one hour. The product is then extracted with 300 cc of ethyl acetate (100-, 100-, 50- and 50 cc portions). The solvent is distilled off *in vacuo* over a water-bath. To the residue 5 cc of 5% sulphuric acid are added and mixed for ten minutes, finally 40 cc of distilled water are added and the solution is

raised slowly to boiling One gram of paraffin is added and the mixture filtered The filtrate is alkalinized with ammonium hydroxide and then 20 cc of potassium permanganate (1:10) are added The excess potassium permanganate is taken up by hydrogen peroxide The resulting mixture is heated for 15 minutes on a water bath, filtered and the precipitate is washed The filtrate is extracted with four 20 cc portions of chloroform This extract, after the removal of the chloroform, yields silky crystals of caffeine Analysis of four samples met the requirements of the food and drug decree of the French authorities and the other was slightly overstrength—A GUILLAUME and C LEFRANC *Bull sci pharmacol*, 42 (1935), 14 (C T I)

Copaiba Balsam—Examination of Several samples of copaiba balsam of known purity and one of gurjun balsam were subjected to the tests prescribed in the various pharmacopœias Van Itallie and Nieuwland's color reaction is not specific, the ammonia reaction for detecting fixed oils is inapplicable to mixtures of copaiba and gurjun Vodge, Alcott and Turner's reaction for gurjun (blue coloration on pouring over sulphuric acid a solution in glacial acetic acid containing sodium nitrite) is fairly characteristic, it seems to depend on the presence of large quantities of cadinene which is also present but only in traces, in copaiba, in doubtful cases the test should be repeated and compared with the color obtained on a copaiba of known purity to which 1% gurjun is added The samples examined had a specific gravity ranging from 0.958 to 0.990, the non-volatile residue varied within wide limits, but was always greater than 45% The acid number varied from 62 to 92.5, the saponification number from 66 to 96, and the Wolff precipitation number (addition of water to an alcoholic solution of balsam) varied from 12 to 14 for copaiba and from 3 to 4 for gurjun The essential oil separated on steam distillation of the balsam had an optical rotation of from -7.50° to -37.75° for copaiba and of -69.30° for gurjun—J W BIRZA *Aan P van der Wielen* (1934), 76-90, through *Chimie & Industrie*, 33 (1935), 423 (A P C)

Copper—Determination of, in Organic Matter Ansbacher's method, with some modifications, was used for determining copper in organic matter previously ashed Instead of placing the crucible containing the copper sulphide in a glass triangle over a crystallizing dish, it is placed in a 50 cc Erlenmeyer flask the top of which has been cut off so that the crucible will fit into it to a depth of about 1.25 cm A lip is also made in one side of the flask for pouring and rinsing out the copper nitrate and sulphate solution The use of the Erlenmeyer flask decreases the danger from copper contamination and loss of the sample due to the crucible tipping over To dissolve the copper sulphide and evaporate the copper nitrate and sulphate solution the Erlenmeyer flask is placed on an aluminum water-bath which rests on an electric hot plate having aluminum top and sides The hot plate is placed in a metal free hood lined with asbestos sheet rock Evaporation to dryness can usually be completed on the water bath, but it may be necessary to place the flask directly on the hot plate for a few minutes It is also desirable as Ansbacher suggests, to have a glass plate over the crucible and flask to exclude copper contamination—O SHEETS, R W PEARSON and M GEIGER *Ind Eng Chem, Anal Ed*, 7 (1935), 109 (E G V)

Cyanide—Separation and Detection of The apparatus consists of two 15 x 180 mm test tubes and a 100 cc Erlenmeyer flask connected by rubber and glass tubing Two tenths Gm of the substance to be analyzed for cyanide (or 3 cc of a prepared solution, made by treating 3 Gm of the substance with 50 cc of 1.5M sodium carbonate boiling for 3 minutes, and filtering) is introduced into the flask The first test-tube contains 6 cc of 3M hydrochloric acid and the second 10 cc of 6M sodium hydroxide A plug of absorbent cotton in the neck of the flask prevents any of the liquid from being carried over into the alkali By slowly turning on the compressed air the acid in the first test-tube is forced over into the flask A slow stream of air is then allowed to bubble through the flask for 30 minutes Any cyanide in the mixture is thus carried over into the second test-tube, where it is absorbed by the alkali It is detected in this solution by means of the Prussian blue reaction carried out as follows To the alkaline solution are added a few drops of a freshly prepared 1M ferrous sulphate solution the mixture is heated almost to boiling and then thoroughly cooled The solution is then carefully neutralized with 12M hydrochloric acid and a few drops of 1M ferric chloride solution are added The formation of a blue precipitate or with very small amounts of cyanide of a blue or blue green coloration indicates the presence of cyanide—L J CURTMAN and S M EDMONDS *Ind Eng Chem, Anal Ed*, 7 (1935), 121 (E G V)

Essential Oils—Estimation of Alcohols in A report given by S Sabetay at L Academic

des Sciences in which he detailed a method of determining the content of primary and secondary alcohols, which reduces the time of estimation considerably, with results approximating very closely to those obtained by the process usually employed. This latter consists in acetylation with acetic anhydride by heating for two hours on a sand bath in the presence of anhydrous sodium acetate. With the readily dehydratable tertiary alcohols, satisfactory results are only reached by formulation in the cold by means of a mixed aceto formic anhydride—an operation taking at least three days on account of the slow esterification of these alcohols. In the preparation of acetates of tertiary alcohols the catalytic action of phosphoric acid has been used for the acetylation in the cold by means of acetic anhydride. To prepare the catalyzer 10 Gm of orthophosphoric acid are mixed with 90 Gm of acetic anhydride. The catalyzer keeps well in spite of the yellowish tint it develops after some time. Seven to 10 cc of the essential oil for analysis are dissolved in 14 to 20 cc of acetic anhydride, then 1 to 1.5 cc of the catalyzer is added, it is only necessary to cool the container if the temperature due to the disengagement of heat should rise above 50° C. The mixture is left for 15 minutes, then 50 cc of distilled water are added and the whole is heated over a water bath for ten minutes, boiling and shaking frequently. It is now decanted and washed successively with 25 cc of saturated brine, 25 cc of brine containing 1 per cent of potassium carbonate, 25 cc of brine and 15 cc of water, in the case of cetyl alcohol only three washings with 50 cc of hot water are necessary. It is then dried over sodium sulphate and hydrolyzed for an hour on the water bath by alcoholic seminormal caustic potash. Two hydrolyses are made and the mean taken. A table showing the results obtained by the rapid acetylation compared with those by the ordinary method is given—*Perf and Ess Oil Rec*, 26 (1935), 44 (A C DeD)

Identification Numbers of Drugs and Galenicals—V **Copper Numbers of Drugs Used Most** The reducing power (Copper Number) of 37 vegetable drugs in various forms using Fehling's solution are reported. Other data included in an elaborate table for these drugs are (1) % moisture, (2) ash content of air dried and water free drugs, (3) Copper numbers of air dried and water free drugs, (4) Inversion Copper numbers of the air-dried and water-free drugs and (5) Copper Number Quotients $\frac{\text{Cu No In}}{\text{Cu No}}$ —J A MULLER *Apoth Ztg*, 50 (1935), 93 (H M B)

Indophenine Reaction—Use of, for the Identification of Some Organic Polyacids Many acids form thiophene derivatives when heated with phosphorous trisulphide and consequently give the indophenine reaction. A small quantity of the acid is neutralized with Na CO₃, evaporated to dryness and mixed with phosphorous trisulphide. A drop of a solution of isatine in H₂SO₄ is added and the mixture is heated until vapors develop. A blue color is developed, when the reaction is positive. The latter is sensitive to 25% with succinic acid, 25 with fumaric acid, 50 with maleic and malic acid, 100 with pyrotartaric acid and 250% with tartaric and citric acid. The presence of glutaric, suberic, azelaic and sebacic acid disturbs the reaction. The addition of some drops of a 2.5% solution of lead acetate permits the performance by the method described, though the reaction is less sensitive. All acids which give the reaction can be destroyed with KMnO₄ with exception of pyrotartaric and succinic acid. This permits the investigation of the latter in mixtures.—José VÁZQUEZ SÁNCHEZ *La Farm Mod* 46 (1935) 58 (A E M)

Lactic Ferments—Determination of Biologic Value of The following method is given. Inoculate aseptically 500 cc of sterile milk with an average sample of the product, or 4 ampuls or 6 Gm in the case of tablets or powder. Determine the acidity of 10 cc of the mixture at the beginning, using 0.1N sodium hydroxide and 10 drops of 1% phenolphthalein. Incubate at 37° C. Note the rapidity of coagulation and the kind of curds formed. Determine the acidity after 6 hours of incubation. A table for comparison is given. The product should not give an appreciable reaction for catalase.—M VAN HAUWAERT *J pharm Belg* 17 (1935), 151 (S W G)

Lacto-flavins—Optical Activity of In neutral solution lacto flavin is optically inactive. In alkaline solution it is levorotatory. In order to compare it with stereoisomers of synthetic flavins C₁₇H₁₂N₄O₆ it is important to know its optical activity under different conditions

$$\begin{aligned} [\alpha]_D^{20} &= \pm 3^\circ (2N \text{ H}_2\text{SO}_4) \\ [\alpha]_D^{15} &= \pm 5^\circ (\text{H}_2\text{O } N/100 \text{ NaCl}) \end{aligned}$$

$$\begin{aligned}
 [\alpha]_D^{20} &= -114^\circ \text{ (N/75 NaOH)} \\
 [\alpha]_{C_D}^{20} &= -70.5^\circ \text{ (N/75 NaOH)} \\
 [\alpha]_D^{20} &= -115^\circ \text{ (N/10 NaOH)} \\
 [\alpha]_{C_D}^{20} &= -60^\circ \text{ (N/10 NaOH)} \\
 [\alpha]_D^{20} &= -110.5^\circ \text{ (N/5 NaOH)} \\
 [\alpha]_{C_D}^{20} &= -60^\circ \text{ (N/5 NaOH)} \\
 [\alpha]_D^{20} &= -78^\circ \text{ (1 4/N NaOH)} \\
 [\alpha]_{C_D}^{20} &= -34^\circ \text{ (1 4/N NaOH)} \\
 [\alpha]_D^{20} &= -123.5^\circ \text{ (Molybdic Acid)} \\
 [\alpha]_{C_D}^{20} &= -71^\circ \text{ (Molybdic Acid)} \\

 [\alpha]_{C_D}^{20} &= +219.5^\circ \text{ (Borax)} \\
 [\alpha]_D^{20} &= -59^\circ \text{ (Glacial Acetic Acid)} \\
 [\alpha]_{C_D}^{20} &= -370^\circ \text{ (Glacial Acetic Acid)}
 \end{aligned}$$

The yellow [sodium] light optical activity is twice as great as that of the red (cadmium) light. There is a connection between the optical activity and light sensitiveness of lacto flavin in alkaline solution.—R KUHN and H RUDY *Ber*, 68 (1935), 169 (G B)

Magnesium Carbonate—Analysis of Eight samples of magnesium carbonate showed a magnesium oxide content varying from 41.8% to 48.5%. If we assume that $MgH_2C_6H_4O_7$ and $K_2HC_6H_4O_7$ or $Na_2HC_6H_4O_7$ are desired in the finished solution of magnesium citrate, the U S P X formula has insufficient citric acid. The formula should probably be flexible and provide for varying amounts of magnesium oxide in the carbonate used. Precipitation logically takes place more rapidly and in greater quantity if a carbonate high in oxide is used. A more uniform product from standpoint of chemical composition and physiological action could be obtained by use of a flexible formula.—H R BOWERS *J Am Pharm Assoc*, 24 (1935), 128 (Z M C)

Medical Products—Tollens' Reaction in Analysis of Tollens' reagent (Ammoniacal $AgNO_3$) gives reaction with a large number of reducing substances. Non-reducing admixtures usually do not interfere with the reduction of the reagent to metallic Ag. The determination of guaiacol in presence of terpinol and iodoform was studied. One molecule guaiacol corresponds to 2 atoms of metallic Ag. The assay should be performed with about 0.05 g guaiacol. It gives rather accurate results (4% error).—R SAN MARTIN CASAMADA *La Farm Mod*, 46 (1935), 89 (A E M)

Monosaccharides—Microchemical Detection of Relatively large quantities of material are required for the characterization of monosaccharides. The sugar to be studied is placed with the reagent upon a microscope slide or in a glass capillary. After reaction is complete, the resulting crystals of hydrazone or osazone are covered on a slide with a cover slip and washed under observation with a microscope. Recrystallization, in most cases, is superfluous. The melting point is determined after drying for 3 minutes. Micromelting points so determined are in agreement with the reported macromelting points. The identification of a sugar requires an average of about 1 mg of sugar and may be finished in about 1/2 hour. The same reagents are used as by macromethods.—P FISCHER and W PAULUS *Arch Pharm* 273 (1935), 83 (L L M)

Morphine—Colorimetric Microdetermination of, in Opium, Its Preparations and in Morphine Syrup. The reagent is a solution of 140 Gm anhydrous sodium carbonate, 20 Gm disodium phosphate and 70 Gm molybdic acid in 500 cc water which is brought to one liter by the addition of 200 cc nitric acid and water. If a morphine solution is to be tested, 10 cc is mixed with one cc of the reagent and a drop of nitric acid, after 10 minutes, 20 drops of ammonia water is added. A blue color develops which is in proportion to the morphine content and suitable for colorimetric comparison with a standard. Morphine hydrochloride syrup can be tested without extracting the morphine. Opium and its preparations are extracted with a calcium hydroxide solution. The solution is acidified, alkalinized with ammonia and extracted with a mixture of 8 parts chloroform and 2 parts secondary propyl alcohol. The mixture is evaporated and the residue is dissolved in hydrochloric acid. The solution is ready for the test.—J A SANCHEZ *Semana medica* (Buenos Aires) 42, 1 (1935) 191 (A E M)

Morphine—New Method for Determination of, Especially in Opium. The method depends upon the conversion of the alkaloid to a readily crystallizable derivative by means of 2,4-dinitro-

chlorobenzene Two methods are described, the one cumbersome but affording a high degree of precision, the second simplified yet sufficiently accurate for the requirements of most pharmaceutical laboratories The latter follows 4.50 Gm of finely divided opium are triturated with 1.5 Gm of calcium hydroxide and 10 cc of water Thirty-five cc of water are added, the mixture is agitated vigorously for $\frac{1}{2}$ hour and then transferred to a dry folded filter paper To 26 Gm of filtrate (= 2.50 Gm opium), placed in a 100 cc Erlenmeyer flask are added 38 Gm methanol, then 7 Gm of alkaline potassium oxalate solution containing in 100 Gm 18.4 Gm of neutral potassium oxalate ($C_2O_4K_2 + H_2O$) and 10 cc of normal potassium hydroxide The mixture is heated on a water-bath for $\frac{1}{4}$ hour and then is allowed to cool Fifty-six Gm of filtrate (= 2.00 Gm of opium), obtained by filtering through a covered 8 cm filter paper, are mixed with a solution of 0.6 Gm of dinitro chlorobenzene in 10 Gm of methanol and 10 Gm of water are added The clear solution is set aside over night for crystallization The precipitate is then collected on a pledget in a 5-cm funnel, adhering mother liquor is removed with gentle suction and by washing with 5 cc of methanol, followed by 5–10 cc of water until the filtrate is neutral to litmus The precipitate is washed with the pledget into a wide mouthed, 100 cc Erlenmeyer flask, 10 cc of 0.1N hydrochloric acid is added and the mixture warmed on a water-bath until solution is effected To the cooled solution are added 5 Gm of sodium chloride, 3 drops of methyl red solution and sufficient water to bring the total volume to 50 cc The excess acid is titrated with 0.1N potassium hydroxide 0.11 is added to the required number of cc of 0.1N acid to correct for the amount of morphine derivative remaining in solution The total number of cc of 0.1N hydrochloric acid required multiplied by 0.02852 gives the amount of morphine in 2 Gm of opium Methods are described also for the determination of morphine in simple solution, in mixed opium alkaloids, in Pantopon and in opium concentrates The preparation and physical constants of morphine-2,4-dinitrophenyl ether are given —C MANNICH *Arch Pharm*, 273 (1935), 97

(L L M)

Narcotics—Detection of, in Sense of Opium Law According to the law the following are listed Cocaine, ecgonine and its esters, morphine, diacetylmorphine (heroin), benzylmorphine (peronine), dihydroxycodaine (Diconid), dihydromorphinom (Dilauid), dihydrocodemon (Euco dal), dihydromorphine (Paramorfan), acetyldihydrocodemon (acetyldimethyl dihydrothebaine, Acedicon) thebaine, codeine, ethylmorphine (Dionin), also genomorphine and morphinaminoxide, which are of little importance in Germany Others of importance are Narcophin, Holopon, Laudanon and Pantapon These substances may be divided into groups as a basis for their analytical separation (1) Morphine and related bases and (2) Cocaine, its related bases and substitutes If a small amount of the substance in question on a slide is dissolved in water and yields much precipitate with Mayer's reagent or with potassium iodide iodine solution, the substance belongs to the two groups mentioned above If only a little precipitate or a slight reaction occurs, this is due probably to adulterants or to preparations containing the above substances and in such cases the bases must be separated by the Stas Otto process If a strong reaction occurs with the above reagents, test a small amount of the substance with Marquis reagent using a small shallow porcelain dish or slide placed on a piece of white paper in order to observe color changes better If no color arises, the 2nd group is present, group 1 produces a strong coloration immediately or in a few seconds The groups designated may be further separated by the scheme outlined —GRIEBEL *Apoth Ztg*, 50 (1935), 15

(H M B)

Nylander Test—Simple and Rapid Procedure for The author found that since bismuth subnitrate is soluble in 50% sodium hydroxide solution, the potassium and sodium tartrate becomes superfluous Such a solution of bismuth oxide in alkali will give a quick, fairly sensitive test for sugar in the urine A few drops are heated with a drop of urine in a watch glass or test-tube The sensitivity is easily 0.1% which is satisfactory for practical use —K SCHERINGA *Pharm Weekblad*, 72 (1925), 194

(E H W)

Phosphorus Determinations—Rapid Method of Preparing Biological Materials for In making phosphorus determinations on biological materials, the addition of perchloric acid during the sulphuric-nitric acid method of digestion decreases the time required for the digestion from hours to about 15 minutes A water clear solution is obtained The method of digestion results in no loss and the phosphorus may be accurately determined on the solution volumetrically, gravimetrically or colorimetrically without interference —H W GERRITZ *Ind Eng Chem, Anal Ed*, 7 (1935), 116

(E G V)

Potassium Permanganate—Employment of Potassium Ferrocyanide in Standardization of Dilute To each cc of 0.01*N* potassium ferrocyanide add 2 cc of *N* sulphuric acid and titrate with 0.01*N* potassium permanganate in the presence of 0.05 cc of 0.1 per cent aqueous erioglaucine. Subtract an end-point correction of 0.012 cc from the titer for the erioglaucine.—E J DE BEER and A M HJORT *Ind Eng Chem, Anal Ed*, 7 (1935), 120 (E G V)

Pyrethrum Products—New Method of Analysis of An investigation of the composition of the ether extract of pyrethrum revealed the presence of the following free acids Mono and di carboxylic chrysanthemic acids, a resin acid having a neutralization no of 300, protocatechuic acid, iso-valerianic, caproic, lauric palmitic oleic, linoleic and linolic (the fatty acids in very small amounts only), all these acids, except the phenol carboxylic acids, are also present in the combined state, together with traces of acids very difficult to identify and which will be further investigated. The interference of free and fatty acids on present methods of determining pyrethrins is discussed at length, and a method which is based on the solubility in water of the barium salts of chrysanthemic acids, which overcomes the above noted drawbacks and which is applicable to all products containing pyrethrum, is described in detail. It is essentially as follows Saponify the pyrethrum extract with normal alcoholic potash, evaporate the alcohol under reduced pressure on the water bath, take up the residue in distilled water, saturate with sodium chloride add barium chloride, filter acidify the filtrate with hydrochloric acid, extract the liberated chrysanthemic acids with ether, wash with sodium chloride solution, evaporate the ether take up in a little alcohol and titrate total chrysanthemic acids with *N*/5 alcoholic caustic potash, acidify the titrated solution with excess normal sulphuric acid, steam distil and determine monocarboxylic chrysanthemic acid in the distillate by standard methods, the dicarboxylic acid is obtained by difference. The method was applied to the analysis of pyrethrum flowers cut at various stages of development and showed that the pyrethrins contents varied very considerably at different stages, so that in accurate investigations the exact stage of development of the flowers must be specified. The pyrethrin I and II contents are substantially equal. The presence of methyl pyrethrolone was confirmed.—J RIPERT *Ann fals*, 27 (1934), 580-595, 28 (1935), 27-38 (A P C)

Rotenone—Determination of, in Derris Root and Resin The carbon tetrachloride method for determining rotenone has been examined. The method gives low results if the rotenone content of the resin is below 17 per cent, and is seriously in error if the rotenone content is below 10 per cent. The rotenone carbon tetrachloride crystals are probably only 80 to 90 per cent pure.—R S CAHN and J J BOAM *J Soc Chem Ind*, 54 (1935), 37T (E G V)

Sulphur—Determination of Small Amounts of, in Certain Organic Compounds The authors of this paper have worked out a method in which they use an apparatus for spraying a jet of the substance mixed with air and carrying the spray into a specially designed combustion tube. Numerous examples of analyses are given and the results seem to be very satisfactory and the elaborate apparatus employed is well illustrated. The original article should, however, be consulted for details.—N STRAFFORD and H CROSSLEY *Analyst* 60 (1935), 163-169 (A H C)

Sulphur—Oxidation of, in Organic Chemistry—Application to Determination of A study was made of the action of various oxidizing agents on sulphur compounds such as mercaptans, disulphides, thio-ureas thiocyanates thiophenes sulphoxides sulphones sulphonic acids and sulphamids. Results indicate that sulphur in the organic molecule can be satisfactorily determined in this manner. The procedure is as follows. A known weight of the substance to be analyzed (about 0.5 Gm.) 20 cc of sodium hydroxide solution and 50 cc of distilled water are introduced into a 1 liter flask. The mixture is cooled and 25 cc of 4% alkaline potassium permanganate is introduced. The mixture is agitated from time to time during one half hour, and then heated (if organic compound is volatile, heating must be very gentle). The heating is maintained for one hour during which time small quantities of permanganate solution are added until a red color persists. The mixture is then cooled and excess hydrochloric acid is added. The excess chlorine is then expelled by heating. After washing down the apparatus with a little water barium chloride solution (10%) is added until no further precipitation occurs. The precipitate is dried and weighed and the amount of sulphur calculated. Sodium hypobromite also gave very consistent results and a modification of the technique employed in using this oxidizing agent is given. Results are tabulated.—C LEFEVRE and M RANGIER *J pharm chim* 21 (1935) 151 (M M Z)

PHARMACOGNOSY

VEGETABLE DRUGS

Angostura Bark. The botanical history and the chemistry of the plant are reviewed comprehensively—K MEYER *Pharm Ztg*, 80 (1935) 120 (G E C)

Cloves—Sources of Propagation of the clove tree and the collection and marketing of cloves are described—GERT KELLER *Drug and Cos Ind*, 36 (1935), 281-284 (H M B)

Compositæ Flowers—Pharmacognostic Study of The article consists of a table containing the anatomical characteristics of the first three classes of Tubulifloræ, namely Vernoniæ, Eupatoriæ and Asteræ. The table includes a description of the cell wall, cuticle, epidermal cells, stomata, mesophyll and epidermal hairs. The species included are *Pacouina*, *Lampira*, *Chænium*, *Vernonia* (8), *Piptocarpha*, *Elephantopus* (3), *Piqueria*, *Adenostemma*, *Ageratum*, *Stevia*, *Eupatorium* (25), *Mikania* (5), *Adenostyles* (2), *Trilisa*, *Brickelia*, *Liatris* (5), *Haplopappus*, *Aster* (6), *Erigeron* (9), *Conyza* and *Baccharis* (14)—W HIMMELBAUR and W MARTINI DESS *Scientia Pharm* 6 (1935) 13 (M F W D)

Digitalis Leaf—East Indian Report of the investigation of Twenty-nine samples of digitalis leaf grown in Java were investigated comparatively with some European samples. Considerable difference between the East Indian and European leaves was observed. The infusion of the East Indian Leaf showed a stronger cumulative effect. Somewhat different results were obtained in the determination of the Hoekstra fractions (the East Indian leaf had a higher digitaline fraction). The author believes that some of the differences between the European and the East Indian leaves was due to the rapid drying of the latter resulting in its stabilization. Charts and tables of pharmacological data are given—U G BIJLSMA *Pharm Weekblad*, 72 (1935) 255 (E H W)

Drugs—Scheme for Microscopic Examination of Discussion of a scheme for the microscopic examination of drugs—E SKARMITZL and Z BLAZEK *Časopis Českoslov Lékárnictva*, 14 (1934) 301-305 through *Chem Zentr*, 106 (1935), 749 (G B)

Grindelia Robusta, Nutt—Histologic Study of A histologic study of root, stem, leaf bracts and inflorescence of the plant. Special reference is given to the oleo resinous secretory apparatus and its anatomic location—J GIROUX and J SUSPLUGAS *Bull sci pharmacol*, 42 (1935) 89 (C T I)

Kola—Jamaica and Madagascar The most of the kola-nuts on the European market have been coming from Africa these being preferred because of their supposed higher content of caffeine. To verify this a supply of Jamaica kola nuts were obtained, examined and assayed according to the procedure of the Swiss Pharmacopœia. Fifty of the nuts were assayed individually and the average content of purine base was found to be 1.74%. This is well above the requirements of the Pharm Helv V (not less than 1.5%). Forty Madagascar kola nuts were similarly assayed and showed an average of 1.33%—L ROSENTHALER *Pharm Acta Helv*, 10 (1935) 47 (M F W D)

Psyllium Seed—Further Studies on Reference is made to earlier studies. The present report covers examination of new lots of seeds from Spain and France, plants with mature fruit and seed from growers in France and Spain, comparison with herbarium specimens and with standard descriptions of the species involved. Examinations included external morphology, cross sections and the mucilage swelling factor by the method previously outlined. The report is well illustrated. The following conclusions are reached: Good French and Spanish psyllium seeds of the current American market are yielded by *Plantago psyllium* and *Plantago arenaria*, *Plantago psyllium* seed is superior to *Plantago arenaria* seed in mucilage swelling capacity, while most of the French psyllium seed is coming now from *Plantago arenaria* and less from *Plantago psyllium*, occasional lots are mixtures of the two with rarely some *Plantago cynops*—HEBER W YOUNGKEN *J Am Pharm Assoc* 24 (1935) 207 (Z M C)

Rhubarb—Cultivation of Medicinal Russian and Chinese rhubarb are identical in their active constituents. The Russian rhubarbs recommended are *Rheum palmatum* and *R. officinale*. *Rheum Emodi* contains only traces of active constituents—D SHTSCHERBATSCHEW *Sowjet Pharmaz* (Russ Ssovjetskaja Farmacija) 5 Nr 2 25-27 1934 through *Chem Zentr* 106 (1935) 270 (G B)

Syzgium Jambolana—Notes on In literature the cortex and fruits appear also under the names *Eugenia Jambolana* Lam and *Calyptranthus Jambolana*, W In medicine the fruits, rinds and leaves are used as aromatic astringents and as a dye The pharmacognosy of the fruits and rinds as well as the investigations of various workers are reported —DRAPIEN *Apoth Ztg*, 50 (1935), 112 (H M B)

ANIMAL DRUGS

Fish Liver—Preservation of, for Oil Production To prevent destruction of vitamins by enzymic and bacterial action the liver is heated by means of steam to about 90° and immediately before, during or after the heating Ten Kg sodium chloride per 100 Kg liver is dissolved in the mass After the cooling of the mass, the container is closed —ANTIESPLSKAD T FERROSAN Dan Pat., 48,412, Feb 19, 1934

Musks—Natural Natural musk, as understood by the perfumier, is an animal secretion and like other natural fixatives, ambergris, civet and castoreum, is valued not only for its own odor and fixative qualities, but because it can impart a vitality to a perfume Ambergris is the only one which is apparently unconnected with the sexual life of the animal producing it Castoreum, civet and musk are all glandular secretions and their production is connected with the breeding season The musk of commerce is produced by the musk deer (*moschus moschiferus* L.) The musk pod is entirely absent in the female and is a small more or less spherical sac, situated near the animal's abdomen It varies in weight from about 10 to 50 Gm, when trimmed of hair and superfluous skin When cut open, the pods consist of about 70% of their gross weight of a black or reddish brown granular substance which is the musk itself When exposed to the air it has a strong ammoniacal odor There are many varieties of musk offered under such names as Assam, Nepaul, Yunnan Indian, Tonquin and Cabardine Tonquin musk provides 80 to 85% of the world's supply The deer producing this quality live on the southern slopes of the Thibetan mountains Adulteration is carried out fairly widely by the extraction of the genuine musk through the natural vent on the exterior side of each pod and the substitution of most anything A pure dry musk should contain from 50 to 75% of water soluble material, but only 10 to 15% of matter soluble in alcohol The moisture should not exceed 12 to 15% and the ash not more than 8% Muskone has been isolated from musk to the extent of from 0.5 to 2% Perfumers use the musk in the form of a 3% solution in alcohol and the longer the tincture is kept, the better, six months being accepted as the minimum —A C STIRLING *Chem and Drug*, 122 (1935), 316 (T G W)

PHARMACY

GALENICAL

Atropine Group—Homeopathic Tinctures of Twelve homeopathic preparations prepared from *Belladonna* (plant, mature and immature fruits, root and seed), *Hyoscyamus niger*, *H. scopolia*, *Datura stramonium* (herb and seed), *Datura arborea* flowers, *D. metel* seeds and *Duboisia* are reported containing alkaloids of the atropine group The tinctures and the homeopathic dilutions of these preparations are characterized according to their reaction to the Vitali and Fehling tests, their alkaloidal contents are determined and the completeness of the extraction of the total alkaloidal content is discussed The tinctures are biologically tested on the eye of the cat for their mydriatic action and the limits determined for this action The fluorescence phenomena of the tinctures and their dilutions are fixed, measured according to Rojahn and the detectable limits determined This method permits certain distinctions between *Belladonna* and *Hyoscyamus niger* and between the other two *Hyoscyamus* species due to their scopoletin content The capillary power and its fluorescence phenomena is also described the results of which correspond to the previously mentioned determinations The results are tabulated in five tables —A KUHN and G SCHAFER *Pharm. Zentralh.* 76 (1935), 49 (E V S)

Cherry Laurel Water and Solution of Hydrocyanic Acid—Preservation of, by Paraffin Oil and Vaseline Stability studies on cherry laurel water and hydrocyanic acid solution revealed, (1) placing a layer of vaseline or paraffin oil over the surface of the preparation prevents deterioration considerably with vaseline being the better preservative, (2) 1% tartaric acid is a good stabilizing agent alcohol a fair one, (3) preserving in a refrigerator prevents loss of hydrocyanic acid,

(4) containers (glass) with thick walls keep the preparation better than thin walled containers and (5) warmth and light rays hasten deterioration greatly For an every day dispensing set up, the authors recommended a stoppered bottle surrounded with a layer of black paper and provided with an outlet in its base so that the solution or water may be drawn off without disturbing the superimposed layer of vaseline or paraffin oil—A GUILLAUME and G DUVAL *Bull sci pharm* col 42 (1935), 74 (C T I)

Cream or "Watersalve"—Preparation of Tenacious The tenacious mucilage from plants, especially psyllium seed is obtained by rapid boiling The mucilage thus obtained is used to replace swelling drugs such as powdered tragacanth—F FUNCK D R P 603528 Kl 30h from 16/1 1932 rendered 10/10/1934 through *Chem Zentr* 106 (1935), 109 (G B)

Ipecac—Contribution to the Knowledge of the Extraction of Ipecac root contains the alkaloids cephaeline and emetine which must be extracted quantitatively and the alkaloids psyllotrine hydroipecamine and ipecamine, saponins ipecacuanhin (a glucoside) and ipecacuanhic acid (a tannin like substance) all of which, according to previous research seem to be without desirable activity In previous work on ipecac the following variables have been taken into account Fineness of the powder, period of heating, combinations of extraction media and concentrations of the solvents In this paper we have chosen to vary the maceration process while maintaining a constant temperature and pressure thereby eliminating these factors from consideration As variables we have chosen the fineness of the powder the alcoholic strength of the menstruum and the time allowed for the action of the solvent on the drug Cartagena Ipecac of the U S P X was separated by hand into gray Cartagena roots smooth roots with rhizomes, and red-brown roots which were then dried to constant weight at 40° C Total ash determinations were run on each group, and determinations of the alkaloidal content using the method of the Pharm Helv V To study the effect of the fineness of the powder the gray Cartagena roots were powdered in a drug mill to a coarse powder and then sieved through a set of U S P X standard sieves into 6 powders of uniform fineness The results of ash and alkaloidal content determinations show that the finer the powder the higher the alkaloidal content Tinctures were then prepared using powders of the six degrees of fineness prepared above and each was extracted with menstrua containing 35 55 75 and 95 per cent alcohol by volume making 24 tinctures in all Ten parts by weight of the menstruum were weighed into a flask and vigorously shaken with one part of the drug once each hour for six consecutive hours and then filtered through a No 1 Whatman filter The temperature was maintained at 23° C throughout Each tincture was then assayed for alkaloidal content by the method of the Pharm Helv V The dry residue was determined by evaporation and drying to constant weight at 95° C The results were represented graphically A second series of tinctures was prepared from all gray roots of uniform alkaloidal strength the roots being powdered by hand sieved and treated in exactly the same manner The results paralleled closely those of the first set A new shipment of Cartagena Ipecac was obtained sorted and only the gray roots used to prepare a third set of tinctures all factors being kept the same as in the first series except that drug reduced to a No 100 powder of uniform ash and alkaloidal content was used and that the time allowed for maceration was varied into periods of 1 3 24 and 48 hours the same percentages of alcohol being used The drug was shaken vigorously with the menstruum six times at regular intervals depending on the total time allowed for extraction The menstrua containing 35 and 55 per cent alcohol extracted all of the alkaloids in one hour In a final series of tinctures where the process of maceration was combined with pressure by rubbing the drug and menstruum together in a mortar it was shown that hard rubbing and the use of fresh portions of solvent increases considerably the speed of the extraction in the cases of the more concentrated solvents—K STEIGER *Pharm Acta Helv* 10 (1935) 59 (M F W D)

Solution of Iron and Ammonium Acetate, U S P X—Stabilization of Variation in order of mixing ingredients showed no advantage in stability of product and mechanical mixing had no advantage over hand mixing Storage at refrigerator temperature prevented deterioration The addition of acetic acid up to 13 per cent of dilute acid in the finished preparation increased stability Time of precipitation was found to be inversely proportional to the quantity of acetic acid present daily agitation has no effect on time of precipitate formation The addition of alkali in concentrations of 5 per cent or more of alkali exerts a stabilizing influence By exactly doubling the concentration of active ingredients a stable preparation was obtained—W J HUSA and L J KLOTZ *J Am Pharm Assoc* 24 (1935) 125 (7 M C)

Nitroglycerin Tablets—Influence of Method of Preparation of, on Nitroglycerin Content The temperature of drying has much influence on the content of nitroglycerin. The smallest loss was observed in drying at 20° for 5 minutes. Loss depends also on the concentration of nitroglycerin used. Solutions containing more than 1% should not be used.—ZSIGMOND BARI *Magyar Gyógyszerészeti Társaság Értesítője*, 11 (1935) 68-81, through *Chem Abstracts*, 29 (1935), 2303

Tinctures—Evaluation of, Made according to Six Different Procedures Twenty four tinctures were prepared (1) by maceration according to Phar Hung III, (2) by double maceration according to Phar Ital, (3) by digestion according to Phar Hung II, (4) by a treatment on steam bath with reflux cooler for 3 hours, (5) by percolation according to Phar Hung III and (6) by dia-culation in a special 3 tube apparatus. Best colors and transparency were obtained by percolation and dia-culation. Specific gravity varied from 0.89 to 0.91. Dry matter content varied but little, it was lowest in tinctures made by maceration and highest in those made by dia-culation, percolation and steam bath treatment. Ash was lowest in the digested tinctures and highest in the percolated and dia-culated tinctures. Dia-culation and percolation products were highest in active matter, maceration tinctures were lowest.—ZSIGMOND BARI *Magyar Gyógyszerészeti Társaság Értesítője*, 11 (1935), 37-67, through *Chem Abstracts*, 29 (1935) 2303

PHARMACOPŒIAS AND FORMULARIES

British Pharmaceutical Codex—Review of The *monographs* are divided into three sections covering (1) methods of manufacture (2) standards and methods of assay and (3) actions and uses of the drugs in question. The "actions and uses" section is itself subdivided whenever this is possible into (1) pharmacological action and therapeutic use, (2) methods of administration (3) incompatibilities (4) antidotes and (5) doses. In the third section substances occurring in the Brit Phar are included in the Codex and the official standards are also included, as also are the actions and uses of these drugs. Among the substances which are included in this issue for the first time are mercurchrome, liver extract, stomach extract, insulin, peptone, scarletina toxin and antitoxin, specific sera against botulism, dysentery, plague and infections by streptococci, pneumococci and meningococci. In the articles dealing with these sera an account of the typing of the organisms concerned is given, and the bearing upon immunization therapy. The Brit Phar antitoxins (diphtheria, tetanus and gas gangrene) toxins (tuberculin, diphtheria and vaccinia) and "vaccines" (bacterial antigens) are included and the actions and uses described. In the section dealing with the actions and uses of ephedrine, ergot and the pituitary hormones the material has been extended and brought up to date.—L. HORDER *Pharm J* 134 (1935) 210 (W B B)

British Pharmaceutical Codex 1934 The author reviews the B P C 1934 and comments on its legal aspects and its status overseas. The section on Surgical Dressings the Formulary and the Appendices are discussed briefly. Many reasons for revision are given.—C. E. CORFIELD *Pharm J* 134 (1935) 297 (W B B)

British Pharmaceutical Codex 1934—Medical Aspects of The usefulness of the Codex to medical practitioners is found in the correlation of pharmacology and therapeutics. It supplies in one volume a great amount of *ad hoc* information which cannot be obtained in any other place. The detailed activities and uses of drugs and the most appropriate methods of administration are very useful in the writing of prescriptions. A feature of the Codex as a text is the excellent way in which it describes preparations such as elixirs, colloidal solutions, emulsions, etc., and the methods of sterilization—tyndallization, pasteurization etc.—J. ORR *Pharm J*, 134 (1935), 233 (W B B)

British Pharmaceutical Codex 1934—Pharmaceutical Aspects of Among the vitamin preparations contained in the Codex are (1) Liquor Vitamin A, a standardized preparation, and (2) Extract of Malt with Vitamins containing 1% of Liquor Vitamin A and 1.5% of Liquor Ergosterols. B P with Extract of Malt. No official Codex preparations of vitamin C are included except fresh orange and lemon juice and their concentrated preparations. Incidentally the Codex states that lemon juice is stable at room temperature for at least fourteen months if the *pH* is kept at its natural acidity point of 2.2 even though it may be heavily infected with moulds and yeast. Injection of Sodium Morrhuate and Injection of Quinine and Urethane are two interesting Codex preparations. The latter will deposit on cooling and the former may do so but

both will clear on warming they should be warmed prior to injection Peptone, for injection purposes is required by the Codex to be free from more than traces of histamine Digitalin of the Codex is now standardized for a biological assay has been introduced whereby this mixture of glucosides is assayed and standardized just as *Digitalis Pulverata* is It can be given either subcutaneously or intramuscularly and a 3% injection is included In the Formulary it is suggested that *Collyria* be not prescribed with an aromatic water as the basis because of the difficulty of sterilization *Nebulae* should be prepared with *Paraffinum Liquidum Leve B P C*, which has a lower specific gravity and lower viscosity than the official liquid paraffin The formulas for emulsions are designed for hand made preparations, and when such are made in a homogenizer the quantity of gum may be reduced otherwise the emulsion would be far too thick Another revolutionary change is the introduction of a dye, azorubrum intended to replace cochineal The method of preparing green extract of belladonna has been radically altered It is no longer made from fresh belladonna leaf juice but is an alcoholic extract which is assayed and then adjusted with liquid glucose to 1% of total alkaloid —H BERRY *Pharm J*, 134 (1935), 233

(W B B)

Sterilization—Notes A selection of proposed formulas for the Chilean 'Formulario Oficial de la Asquifa' includes Injection of Hexamethylenetetramine and Injection of Morphine Hydrochloride Mercurial solutions for injection as follows Injection of Mercuric Cyanide Injection of Mercurochrome and Injection of Mercuric Iodide These mercurial injections which contain the equivalent of 1% of mercury are supposed to be isotonic and neutral —*Pharm J* 134 (1935) 235

(W B B)

Swiss Pharmacopœia—Review of The new Swiss Pharmacopœia contains 1050 items 304 new items have been added and 108 have been dropped from the 4th edition Besides 43 pages of introduction it contains 1244 pages The book is divided into four parts, *viz*, introduction general part, special part (containing the monographs) and tables History is given from the Ticinese Pharmacopœia of 1844 (the first cantonal Pharmacopœia) to the present time The committee for the 5th edition was appointed in 1922 the work of revision requiring 10–11 years The general part of the Swiss pharmacopœia is discussed at length the discussion involving drugs pharmaceutical specialties methods for determining weights measures temperature and other constants The reviewer speaks of the new Swiss Pharmacopœia as a *modern pharmacopœia* —T POTJEWIJ *Pharm Weekblad* 72 (1935) 170

(E H W)

Swiss Pharmacopœia—Review of the Monographs of The reviewer discusses the new 5th Swiss Pharmacopœia with special reference to the monographs These are discussed as to form content tests etc Botanicals chemicals tinctures decoctions emulsions pills, galenicals etc are considered in groups —T POTJEWIJ *Pharm Weekblad* 72 (1935) 214

(E H W)

NON OFFICIAL FORMULÆ

Astringent Lotions These lotions should be called 'stronger lotions' and probably are more effective in correcting oiliness with which blackheads are associated rather than refining coarse pores The following are some type formulas (1) Glacial acetic acid 2.00%, zinc sulphate 0.15%, alum 2% glycerin 4%, menthol 0.08% alcohol 20% water 71.52% perfume 0.25% (2) Alum 2% magnesium sulphate 4% boric acid 2% formaldehyde 0.1% glycerin 3% alcohol 20% water 68.7% perfume 0.2% (3) Aluminum chloride 2% boric acid 1% glycerin 4% alcohol 15%, water 77.75%, perfume 0.25% Dissolve the perfume oil in alcohol and the water soluble chemicals in water and stir in the perfumed alcohol mix thoroughly and filter —ANON *Drug and Cos Ind* 36 (1935) 39

(H M B)

Cleansing Cream—New A cream which does not separate in summer and gives a good lather when mixed with water and is recommended for sensitive skins and as an adjunct in the treatment of acne is made as follows Stearic acid 20% liquid petrolatum 5, triethanolamine 5, coconut oil soap water 40 glycerin 5 Heat the first 3 ingredients to 85° heat the glycerin and water to the same temperature and dissolve the coconut oil soap maintaining the temperature Add the soap solution to the stearic acid slowly and with stirring and continue stirring until cool —J G DOWLING *Drug and Cos Ind*, 36 (1935) 420

(H M B)

Cosmetic Preparations—Borax and Sulphur in The uses of borax especially its combination with glycol are discussed and the following formulas offered *Cold Cream* —Glyco wax—

beeswax 20 parts, liquid petrolatum 120 parts, water 54 parts, borax 2 parts, perfume 1 part. Melt the first three substances together, dissolve the borax in the water and heat both mixtures to 65° C and then stir slowly the borax soln into the wax mixture. Pour out the cream at 50° and add more water, if desired, to make the cream softer. *Vanishing Cream*—This type usually has a silver like appearance due to the use of paraffin, boric acid and glycerin with borax usually added as an antiseptic. 19.5 Kg stearic acid, 0.5 Kg almond oil, 375 Gm KOH, 1 Kg ammonia water (sp gr 0.88), 1 Kg borax, 8 Kg water. Melt the mixt of almond oil and stearic acid, pour the mixt at 82° C into the aq soln of alkali, heat to boiling, cool to 70° C, allow to stand over night. By repeated warming to 38–43° and cooling with occasional stirring a good lustre is obtained in about 3 days, then stir in the glycerin and perfume. *Sulphur* and colloidal S apparently are valueless in the care of the hair because of their insolubility but oil soluble S Sb preparations (sulfoform) seem to show promise since the S is in an ionic form as the SH-ion. Commercial S products have particles of the following sizes: in μ lime sulphur (sulphur layer) > 1, colloidal S (drop like) < 0.6, sulphidal (difficultly discernible structure) 3–6 and 16, extremely finely ground S (cryst) 2–4, mean 10.7, "Wackenrodisch" solution (aq soln of H₂SO₄ saturated with H₂S with cooling and exclusion of light) (crystals with smooth surfaces) 3–50, precipitated S (crystals with curved surfaces) 6.4–16 and 32–48, flowers of S (crystals) 6–40, 32–48, ground cryst S (crystals) 15–80. Final evidence shows that borax is in demand in these preparations on the basis of physico chemical properties, S, however is a substance which presupposes a chemical dermatological knowledge for its use and without this is purposeless.—TH. RUEMELE *Riechstoff Ind*, 10 (1935), 22–25 (H M B)

Cetyl Alcohol—Applications of, in Cosmetics. Cetyl alcohol used in the base of non fatty creams has been found to be readily absorbed by the skin. As a tested formula the following mixture is recommended: 70 parts vaseline, 20 parts paraffin, 10 parts cetyl alcohol, 5 parts anhydrous lanolin, with 100 parts water. The addition of cetyl alcohol proved to have a marked retarding effect upon the onset of rancidity and, moreover, increased greatly the capacity for taking up water.—DR. S. MALOWAN *Perf and Ess Oil Rec* 26 (1935), 52 (A C DeD)

Cold Balms. The following experimental types are offered: (1) *Petroleum Jelly Type*—Menthol 0.7% methyl salicylate 5.8%, camphor 8%, eucalyptol 5%, mustard oil 0.5%, soft short fibre, white petrolatum 80%. (2) *Petroleum Jelly Type*—Menthol 0.7%, chloral hydrate 9%, camphor 9%, methyl salicylate 10%, oil of cade 5%, soft, short fibre, white petrolatum 66.3%. In both cases dissolve the camphor and menthol in the mixed oils, melt the petrolatum at 105° F and stir in the previous mixt. (3) *Water-in Oil Type*—Menthol 1%, mustard oil 1%, eucalyptus 15%, camphor 1% absorption bases derived from lanolin 30%, water 45% stiff, long fibre white petrolatum 7%. Dissolve the menthol and camphor in eucalyptus oil and add mustard oil. Melt the petrolatum and add the lanolin base maintaining the temperature at 45° C, stir in the above mixture followed by water at the same temperature, mix until an emulsion is formed. (4) *Oil in Water Type*—Glyceryl monostearate 12%, white beeswax 6%, methyl salicylate 5%, menthol 1%, camphor 1%, mustard oil 0.5%, water 74.5%. Place the stearate, wax and water in a kettle heat until the stearate melts and the whole becomes white and homogeneous. Dissolve the camphor and menthol in the methyl salicylate and add the mustard oil. Cool the mass to 50° C and add the latter mixture. This product is characteristic of the so called "greaseless balm" type.—ANON. *Drug and Cos Ind*, 36 (1935) 279–280 (H M B)

Cosmetic Products—Hydrogen-Ion Concentration of I. Fatty Skin Creams. This type of preparation is considered a water-in oil type of emulsion, and when put on the skin the fatty portion is resorbed in part while the water remains in a great part on the surface producing a characteristic cooling action by its evaporation. With aqueous suspensions of seven commercial creams of American, English and Spanish origin, using *p* nitrophenol, phenol red and β di nitrophenol as indicators in color comparators three were slightly alkaline, one acid and three neutral, with alcoholic solutions of the same, two were acid, two nearly neutral and the *pH* of three were not determined because extremely turbid alcoholic solutions were obtained. It is concluded that wax free fatty creams in alcoholic solutions are almost neutral while those containing waxes are acid.—KARL PFAFF *Riechstoff Ind*, 10 (1935), 6 (H M B)

Eau de Cologne. A discussion of Eau de Cologne its constituents and manufacture with or without distillation is given. In preparing a cheaper type of perfume use is made of isopropyl alcohol, or a mixture of this with ordinary alcohol as a solvent for the oils. Synthetic oils are

used in place of the extracts employed in the better grade. A method for preparing solid Eau de Cologne is also given—H SILMAN *Perf and Ess Oil Rec*, 26 (1935), 45 (A C DeD)

Feminine Hygiene Jellies The following formulas are offered *Lactic Acid Jelly (Starch Glycerite)*—Lactic acid 1% boric acid 5% glycerite of starch, U S P a sufficient quantity. It is advisable to dissolve the boric acid in the glycerin before preparing the glycerite. An alkali starch produces a more stable jel than an acid starch. *Lactic Acid Jelly (Gum Tragacanth)*—Lactic acid 1.5% boric acid 4% glycerin 10–30%, tragacanth (depending on quality) 2.5–4% water a sufficient quantity. Cooking the tragacanth and selection of a good quality helps preserve the jel. The use of less than 20% glycerin produces a jel which is apt to harden. *Lactic Acid Jelly (Gum Karaya)*—Lactic acid 1.5% boric acid 4%, glycerin 5–20% gum karaya (depending upon quality) 3–5% water, a sufficient quantity. This is a new formula and is growing in popularity. The advantages and disadvantages of each of the above are discussed. Such acids as acetic citric and tartaric have also been used but lactic acid is preferred since it is already present in vaginal secretions and boric acid tends to maintain the acidity of the jelly in the presence of the protective colloids in the semen. Quinine and oxy-quinoline have little or no spermicidal value. All jellies of this type should have some aromatics and a cologne 1–3000 strength is recommended—STOUGHTON *Drug and Cos Ind* 36 (1935) 30, 39 (H M B)

Lip Stick The composition the molds, the coloring the smoothness on application the brightness and the perfuming of lip sticks are discussed—A G AREND *Perf and Ess Oil Rec* 26 (1935) 39 (A C DeD)

Lip Sticks—Chemistry of Dibromo and tetrabromo derivatives of fluorescein have replaced vegetable dyes and alloxan as coloring agents in indelible nontoxic lipsticks. Tasteless castor oil appears to be more satisfactory as a solvent for these colors than butyl stearate and other esters. Irritations to some individuals seems to arise due to compounds produced by removal of Br atoms of the dye molecule and their combination with unsaturated ricinoleic acid. Care should be taken to use the proper proportions of the dye and oil (5% dye and 15% oil). The ideal stick should have the following properties: (1) spread in a thin layer (2) m.p. 118° F (3) possess sufficient tackiness (4) shall not impart an unnatural or stiff feeling to the lips (5) tasteless, (6) permanent in color and should have about 75% vegetable and animal oils and waxes and the remainder mineral oils and paraffins. Lanolin is added to give tackiness and counteracts irritation and drying effects of the dye. Beeswax (not over 10%) and ceresin are used to give consistency and to bind the castor oil. Ozokerite to give a more easily crushable stick. As stiffening agents carnauba wax (10%) and paraffins are added, as a lubricant mineral oil is preferred. Absorption bases to decrease irritation and dryness such as cetyl alcohol are necessary—THORPE DEAKERS *Drug and Cos Ind* 36 (1935) 273–274 280 (H M B)

Passiflorine A correspondent inquires as to the composition of 'Passiflorine' and the Latin nomenclature corresponding to the following: 'Extrait fluide de passiflore,' 'Extrait moux de Saule blanc' and 'Extrait moux de Crataegus oxyac.' The reply is 'Passiflorine' (German 'Passiflorin') consists of,

Extractum Flor Passiflor incarnat	0.5 Gm
Extractum Salicis albæ	0.25 Gm
Alcoholatura Crataegi oxyacanthæ	gtt XX
Sirupus Sacchari et Glycerin q s ad	5 cc

H J VAN GIFFEN *Pharm Weekblad* 72 (1935) 177 (E H W)

Shaving Cream—Latherless A mixture is prepared containing stearic acid 11, lanolin 10, coconut oil 0.3, concentrated ammonia water 1.35, paraffin wax 6, spermaceti wax 2, boric acid 1.5, water 75 parts together with small quantities of menthol, camphor and perfume—GFO D GETTEMULLER and SAMUEL L. GOLDHEIM U S Pat 1991 501 Feb 19 1935 (S W G)

Skin Creams—New Bases for New bases mentioned are (A) *Hydrocerin* and *Boerocerin* which are especially resorbed by the skin. They increase the resorption of creams containing fats and are unsaponifiable and never become rancid. *Hydrocerin* creams produce a fatty appearance on the skin and *Boerocerin* creams leave the skin lustreless, such creams are used as day and night creams and are of value as powder bases. The latter base is used in the preparation of the finest American creams which are very homogeneous and have a constant consistency changing but little with extreme changes in temperature. These properties are due chiefly to the high

cholesterin content (B) *Almecerin and Cefatin*—The former is a bright yellow substance with a slight odor of wool fat, indicating the presence of cholesterin and produces water in-oil creams. The latter which is the base for dry creams of the oil in water type, is of wax like consistency and almost white. The following recipes are of interest (1) *Base*—

	Hard	Medium	Soft
Hydrocerin	8%	8%	5%
Paraffin	8%	—	—
White vaseline	84%	92%	95%

(2) *Cream for Browning of the Skin*—Hard base 40%, liquid petrolatum 10%, distilled water 50%–100% (3) *A Universal Cream*—Hydrocerin 2 17%, paraffin 50/52, 1 17%, liquid petrolatum 8 33%, white vaseline 21 67%, distilled water, 66 66% (4) *American Creams*—Boerocerin 2 66%, liquid petrolatum, 4%, paraffin, 6 66% white vaseline, 20%, glycerin 3 33%, distilled water, 66 35% (5) *Fatty Cream Base*—Almecerin, 50%, water, 50% (6) *Toilet Cream* (easily rubbed in and slightly fatty)—Almecerin, 40% water, 60% (7) *Glycerin Toilet Cream*—Almecerin, 40%, glycerin, 10%, water, 50% (8) *Fatty Cream*—Almecerin, 40%, liquid petrolatum, 20%, water, 40% (9) *Lanolin Cream*—Almecerin, 28 6% lanolin, 14 3%, water, 57 1% (10) *Day Cream Base*—Cefatin, 25%, water, 75% (11) *Glycerin Day Cream*—Cefatin, 25%, glycerin, 75 %, water, 67 5% (12) *Fatty Day Cream*—Cefatin 25%, liquid petrolatum, 6 25%, water, 68 75% (13) *Cream with Mother of Pearl Appearance*—Cefatin, 24 4%, glycerin, 4 9%, water 68 2%, alcohol, 2 5% (14) *Mixed Cream*—Cefatin, 18 9%, stearin 6 3%, almecerin 5 7%, glycerin, 2 6%, water, 66 5% —K. PARF *Riechstoff Ind* 10 (1934) 157–158 (H M B)

Soap—Improving Additions to An invention relating to processes for the manufacture of soaps to which might be added substances has been described by Victor Boulez Its object is to give to the soap pastes improved physical, detergent or other qualities, and to suppress or diminish soap losses The addition of substances removes from soaps their hygroscopic character and increases also their keeping qualities Some of the substances which can be added are enumerated—*Perf and Ess Oil Rec.*, 26 (1935) 68 (A C DeD)

Soaps—Some Disinfecting A discussion of soaps having a definite disinfectant action including carbolic soaps cold process carbolic soaps cresol soaps, iodine soaps sulphur soaps and mercury soaps is given — *Perf and Ess Oil Rec*, 26 (1935), 69 (A C DeD)

Sunburn Preventives Any compound which will fluoresce in ultraviolet light of 2900–3100 Å° will protect the skin from destructive rays of the sun. The following are suggested: benzyl salicylate, menthol salicylate, æsculin, *o*-oxyæsculin, tannic acid, phenyl salicylate, quinine bisulphate, oleate and hydrochloride, ethyl *p*-amino benzoate, sodium naphthol 6,8 disulphonate, β -oxynaphthoic acid, 6-oxy-2-naphthoic acid, α -naphthol 8-sulphonic acid, β -naphthol-3,6 disulphonic acid. As vehicles vegetable oils are useful. The following recipes are offered:

(1) *Oil*—Benzyl salicylate 8%, menthyl salicylate 5, olive oil 43, cottonseed oil 43, perfume 1.

(2) *Lotion*. (a)— β -oxy-naphthoic acid 3%, quinine bisulphate 2, alcohol 15, glycerin 5, rosewater 75. Dissolve the quinine in the alcohol and the acid in the rose water and glycerin, mix and filter. (b) Sodium naphthol 6,8 disulphonate 5%, ethyl *p*-amino benzoate 1, alcohol 15, glycerin 5, witch hazel 74%. Dissolve the 1st ingredient in the witch hazel and the 2nd in the alcohol and glycerin and mix the two solutions. (3) *Creams*—(a) Quinine bisulphate 4%, absorption base from lanolin 25, white mineral oil 15, alcohol 10, glycerin 5, water 40, perfume 1. Dissolve the quinine in alcohol and add glycerin and water, warm to 130° F. Heat the base and oil until melting occurs and then stir in the quinine solution slowly. (b) White beeswax 7%, glyceryl monostearate 12, white mineral oil 5, petrolatum 3, glycerin 3, alcohol 10, benzyl salicylate 5, menthol salicylate 3, perfume 1, water. Heat the stearate, wax, oil and petrolatum together until melting occurs and mix until congealing takes place, then stir in a solution of the other ingredients and stir until ready for filling.—*Drug and Cos Ind.*, 36 (1935) 417–418. (H. M. B.)

Tooth Pastes—Children's The basis of use and manufacture of tooth preparations are discussed. Investigations show that children dislike mouth and tooth preparations because of their odor, taste, grittiness and local astringent or irritant effects. Very fine calcium and magnesium carbonates are recommended as mechanical cleansers with tragacanth as a binding agent, neutral glycerin, a blend of oils of peppermint and anise with saccharin as a sweetening agent. — A. R. BLISS, JR. *Drug and Cos Ind.*, 36 (1935) 409-410, 416 (H. M. B.)

Turtle Oil Creams Only recently, turtle oil has been introduced into pharmaceutical products and information regarding the substance is somewhat scarce. After twelve months' observation, the author claims the oil to be beneficial to the complexion, and when mixed with other nutritive oils makes an ideal wrinkle cream. Best results were obtained when it was used in a 50% concentration with oils such as almond or olive oil. Turtle oil melts at 15° C, being just able to pour, at 20° C, it becomes a liquid, and at 25° C, it is liquid and clear. Turtle oil is not granular to the feel between the fingers at 10° C, although it has that appearance. The author gives two formulas as follows, for anti-wrinkle creams containing turtle oil.

	A	B
Turtle Oil	50	30
Almond Oil	27	46
Lanolin	15	16
Beeswax	8	8

In Formula B, enough turtle oil is included to claim the title, but in this case the object is to aid the assimilation of the others. The most suitable preservatives are the hydroxybenzoic type—C DOUBLEDAY *Chem and Drug*, 122 (1935), 269 (T G W)

Vanishing Creams These have as ingredients (a) triple pressed stearic acid, melting point not less than 56° (10–25%) (b) glycerin, (c) alkalis as potassium and sodium hydroxides, potassium and sodium carbonates to form a soap, the potassium compounds produce a soft cream, sodium compounds a harder cream. The following formulas are suggested (1) Stearic acid triple pressed 20%, KOH 1.5, H₂O 68.5, glycerin 5, alcohol 4, perfume 1 and HCHO solution 0.05. Melt the acid and heat to 212° F, dissolve the KOH in 30% of the H₂O and heat to 212° F, add the hot alkali to the acid with constant agitation and continue until emulsified and add the remainder of the water and glycerin after heating to the same temperature. Add the alcohol in which the perfume has been dissolved, allow to age. This cream is fairly soft. (2) Stearic acid 20% glycerin 10, K₂CO₃ 0.8, Borax 0.4, H₂O 64, alcohol 4, perfume 0.8, HCHO solution 0.05. Heat the acid and glycerin into which has been dissolved the salts to 212° F, melt the acid and heat to the same temperature. Start mixing the water glycerin solution and slowly add the acid, mix until the temperature has reached 120° F, then add the HCHO solution, alcohol and perfume, mix for 20 minutes longer. This produces a harder cream than (1). (3) Stearic acid 25%, lanolin (anhyd) 4.5, triethanolamine 1.35, carbital 9, H₂O 60, perfume 0.15. Heat the acid and lanolin to 160° F, heat the triethanolamine and water to the same temperature and place in a mixer, add the acid mixture with constant stirring, when smooth add the remainder of ingredients and stir until cold. This produces a cream that is absorbed completely and imparts a softness and smoothness to the skin. (4) Stearic acid 20%, KOH 1, cetyl alcohol 1, borax 0.5, glycerin 10, alcohol 5, H₂O 60, perfume 2.5. Procedure as in (1). (5) Stearic acid 18 parts, K₂CO₃ 1.2, butyl stearate 2.5, H₂O 75, perfume 0.3. Procedure as in (1). Butyl stearate in this preparation is a substitute for glycerin which is apt to absorb moisture from the air and give a sticky feeling.—J M WILLIAMS *Drug and Cos Ind*, 36 (1935), 413–414 (H M B)

White Liniment—Suggested Formula for A formula containing triethanolamine crude N N R, is submitted. Both the stirrer method and the bottle method have been tried. White Liniments by other formulas are discussed.—L H BALDINGER *J Am Pharm Assoc*, 24 (1935), 130 (Z M C)

DISPENSING

Chloroform—Safety Color for According to the *Apoth-Zig*, 3 (1935) 32, the question of a safety color for anesthetic chloroform has been considered because of the frequency of accidents through the unnoticed and unintentional employment of chloroform for anesthetic ether. Smell is no absolute protection against interchange of these anesthetics, and for this reason it has been found necessary to search for a distinctive dye for anesthetic chloroform. Results of research have shown that for this purpose dimethylamido azobenzene can be used. A sufficient depth of color is obtained by adding 2 cc of a 0.5% solution of dimethylamido azobenzene (which represents 0.01 Gm of dye) to 50 cc of chloroform. This quantity is stated to be so low that no effect of the dye on the anesthetic is to be expected and the color is easily removed from fabrics.

by ordinary washing or by the use of a weak acid (i. e., vinegar), followed by a thorough rinsing in water — *Pharm J*, 134 (1935), 212 (W B B)

Dispensing—Determination of Reasonable or Permissible Margin of Error in Ointments Different types of ointments which pharmacists are asked to dispense were divided into three classes: those that only have to be transferred from stock container to a dispensing jar, those which involve the incorporation of a liquid with a fatty or hydrocarbon base, those which involve incorporation of a solid with fatty or hydrocarbon base. Three series of tests were made. The objective of the first was to determine effect on capacity of difference in nature of bases: trituration before packing, incorporation of a liquid, incorporation of a solid. Size of jar. The second series aimed to determine variation in capacities of jars manufactured by each of four manufacturers. The third objective was the variation in capacities of jars purchased at random. How these experiments were carried out is explained and the figures are tabulated. The following conclusions were reached: 1. Petrolatum was the lightest of the four bases studied, followed in order by a 50 per cent lanolin and petrolatum mixture, lanolin and benzoated lard when packed as received. 2. The frequency and magnitude of error are greater in cases where the base is packed in the solid state, than in those where the filling is accomplished by melting and pouring, except for benzoated lard. 3. The capacity of jars by weight is decreased by triturating the ointment base on a slab previous to packing in the solid state. 4. The capacity of jars by weight may be decreased or increased by the incorporation of a liquid or a solid with the base, depending on the nature of the liquid or solid and other factors. 5. The percentage of error found was in inverse proportion to the size of the jar. 6. Jars of a designated size made by a single manufacturer do not vary in capacity beyond reasonable limits. There was observed, however, a great variation in the capacity of jars of a designated size made by different manufacturers. The latter variation is due largely to the use of different standards by the manufacturers for fixing capacity. To overcome this condition it is suggested that uniform standards for fixing standards be adopted by the manufacturers, and that the material taken as the basis for formulating these standards be petrolatum because of its comparatively low specific gravity and uniformity with respect to other physical properties. 7. The results of the tests show that it is impossible for a glass manufacturer to prepare ointment jars which will hold the same quantities by weight of the different ointments dispensed on physicians' prescriptions. It is believed, however, that it is possible for them to manufacture ointment jars which will hold within reasonable limits definite quantities of petrolatum or other base selected as a standard. The pharmacist will then be able to dispense the full quantity of an ointment with a low specific gravity. In the case of ointments with a high specific gravity the filling of the jar may be done in such a manner as to leave a concave surface, thereby preventing the ointment from coming in contact with the top of the jar, and also satisfying the patient as to the fullness of the jar. In the case of very heavy ointments such as mercurial ointments it will be necessary to weigh off the quantity prescribed and to dispense it in a jar of the size which it will come nearest to filling. 8. With regard to the margin of error which may reasonably be expected in dispensing where jars of the same manufacture are used, our observations point to a figure which at the outside is twice the standard deviation, or 25 per cent, for $\frac{1}{2}$ and 1 ounce jars, and twice the standard deviation, or 18 per cent, for 2 ounce jars — MARVIN J. ANDREWS *J Am Pharm Assoc*, 24 (1934), 350, 421 (Z M C)

Easton's Syrup Strict adherence to the B. P. method for preparation of Easton's Syrup should keep this preparation water-white for six months or more. A still better method is to use Easton's formula which can be found in "Squire's Companion," 1890 — A. RENNIE *Pharm J*, 134 (1935), 247 (W B B)

Ointments—Eye Starch, zinc oxide, alkaloids and other substances used in the preparation of ointments, can be sterilized with ether. The ointments should be dispensed in tin tubes — J. FABICKI *Wladomosci farmac*, 61 (1934), 157, through *Chem Zentr*, 106 (1935), 747 (G B)

PHARMACEUTICAL HISTORY

Cosmetics—History of, in Modern Times — A. HAUENSTEIN *Riechstoff Ind* 10 (1935), 49–53 (H M B)

German Apothecary Faenze of the Renaissance A historical account of old German Apothecaries. Faenze vessels — FERCHLE *Apoth Ztg* 49 (1934) 1706. History of German Apothecaries, pages 5–12 (H M B)

Hamamelis (Witch Hazel), Extract and Distillate—History of In 1865 while the senior author was in the employ of W J M Gordon and Brother Cincinnati the firm also employed a business representative named Leon Hurtt A brother, F W Hurtt, who was a banker in New York proposed to purchase the right to make Pond's Extract, a proprietary medicine used almost exclusively by Homeopathic physicians In 1915 in a personal interview with Leon Hurtt the author obtained authoritative information and has incorporated it in the present paper Pond's distilled hamamelis came to be used by Eclectic physicians and then by Allopathic physicians though chemists and others decided that it had no therapeutic value It is still in use Hurtt's story relates in considerable detail how the Oneida Indians used it and how the "Golden Treasure" later Pond's Extract was prepared how the business grew and prospered —JOHN URI LLOYD and JOHN THOMAS LLOYD *J Am Pharm Assoc* 24 (1935) 220 (Z M C)

Hospital Pharmacists of Amsterdam—Modification in Instruction and Salary Revision of, in 1857 This extensive article by G Hellinga based upon a number of old records and documents describes the life of the Pharmacist in the Amsterdam Hospital in 1857 and the trend of events which led to revision in his status at that time It is of considerable historical interest —*Pharm Weekblad*, 72 (1935) 318-334 (E H W)

"Patent Medicines" The author relates something of the history of Goddard's Drops, Anderson's Pills Dutch Drops Daffy's Elixir Lockyer's Pills and Stoughton's Elixir —J H HOCH *J Am Pharm Assoc* 24 (1935) 147 (Z M C)

Pharmacognosists of Nineteenth Century—Eminent American The life and work of John M Maisch Edson S Bastin and Julius O Schlotterbeck are the subjects of the first instalment of an historical paper —H W YOUNGKEN *J Am Pharm Assoc* 24 (1935) 148 (Z M C)

Pharmacognosists of Nineteenth Century—Eminent American (See preceding abstract) The men who are considered this time are Albert Schneider Henry Kraemer Lucius E Sayre and Otto A Wall —HEBER W YOUNGKEN *J Am Pharm Assoc* 24 (1935), 215 (Z M C)

PHARMACEUTICAL EDUCATION

Four-Year Curricula in Pharmacy—Comparison of A critical examination was made of courses in so called theoretical and operative pharmacy as outlined in catalogs of member colleges of the American Association of Colleges of Pharmacy, and the results tabulated Comparison is made with the Syllabus requirement with comments by the author as to what he believes best General comments include some important criticisms The curricula of eleven schools offer too many courses which could be corrected in part by combining a didactic with a laboratory course A few offer seminar courses which are of questionable value for undergraduates There is too much variation in credit value of laboratory courses, some received no credit some gave one credit for four clock hours Courses in use of library and literature might be offered in history of pharmacy courses called research and thesis should be elective Twenty three curricula list courses that apparently are review courses for board examinations Not all curriculum outlines and course descriptions are sufficiently complete and clear —HENRY M BURLAGE *J Am Pharm Assoc*, 24 (1935) 228 (Z M C)

Mathematics—Pharmaceutical Some Observations after Twenty-five Years' Experience in Teaching In the days of the two year course classes needed much drill on tables of weights and measures Their learning was a memory feat Continued use clinches the memory part but to day students seem to get mental pictures of weights and measures as something real though they are not as proficient in the multiplication table as formerly High school students of to day do not have the rich experience drawn from farms and villages that their elders did but when one knows what the high schools are trying to teach one finds many students easier to teach The difficulty of teaching about percentage solutions will be largely solved by the statement that will appear in the next Pharmacopœia A teacher's ingenuity is taxed most in getting students to apply what they know Teachers should not accept answers involving fractional weights or measures but insist on weighable and measurable denominations Also utmost accuracy should be required in the class room They will learn by experience when to use round number factors —EDWARD SPEASE *J Am Pharm Assoc*, 24 (1935) 227 (Z M C)

Pharmacy and Academic Standards—Theory of If practical pharmacy is the 'application of the knowledge and training in physics, chemistry, botany, therapeutics, etc., to the making of medicine,' no college is giving too much time to it. Reasons for this statement are briefly discussed—H A LANGENHAN *J Am Pharm Assoc*, 24 (1935), 158 (Z M C)

Pharmacy and Academic Standards—Theory of Some changes are suggested for the outlines in the Pharmaceutical Syllabus and the paper on the same topic by W Paul Briggs is discussed—H M BURLAGE *J Am Pharm Assoc*, 24 (1935), 156 (Z M C)

Pharmacy and Academic Standards—Theory of Time and credit evaluations need adjustment on a sounder economic basis. The entire four year course should be brought into line with other baccalaureate degree courses—W P BRIGGS *J Am Pharm Assoc*, 24 (1935), 153 (Z M C)

PHARMACEUTICAL LEGISLATION

Surgical Dressings Over 1000 samples of surgical dressings are submitted annually to the Manchester Chamber of Commerce Testing House and Laboratory by the 200 Insurance Committees in England, Wales and Scotland, and a certificate of analysis is issued in respect to each stating whether the dressing complies with the requirements laid down in the B P C. Since the adoption of the testing scheme in 1925, the percentage of deficient dressings has decreased by 90%. Deficiencies were found to be less frequent in manufacturers' or wholesalers' wrappings, as required by the Drug Tariff, than in those which were not so wrapped. Many standards for surgical dressings have been amplified and amended and standards have been instituted for such new dressings as batiste, chloramine gauze, euflavine gauze, cellulose wadding, oiled paper, rubber adhesive plaster, zinc oxide plaster, elastic adhesive bandage, zinc paste bandage and cellulose tissue—ANON *Pharm J*, 134 (1935), 301 (W B B)

MISCELLANEOUS

Advertising—Place of a Field Representative in Coöperative Professional Pharmacists can use the mails for reaching physicians but perhaps the ideal way is to combine frequent personal contact with mail contacts. In a community with a number of stores interested in professional business owners can cooperate in a common advertising program. Advertising funds can be pooled and a full-time representative employed—a man who possesses distinct capabilities for the task of "selling the professional services and personalities of the pharmacies" he represents. Such an individual can be helpful in many other ways at the same time—L W RISING *J Am Pharm Assoc*, 24 (1935), 142 (Z M C)

Cosmetics Report on Progress in 1934—K PFAFF *Riechstoff Ind*, 10 (1935), 38-41 (H M B)

Dentists and Pharmacists—Cooperation between Attention is directed to the natural relation between dentistry and pharmacy, to the work of the Council on Dental Therapeutics. The 'Accepted Dental Remedies' is soon to appear in book form. The author discusses ways in which pharmacists can meet the problem—S M GORDON *J Am Pharm Assoc*, 24 (1935), 136 (Z M C)

New Drugs and Their Standards The article consists of a résumé of an address by Dr C H Hampshire at a meeting of the Bath and District Branch of the Pharmaceutical Society of Great Britain held on February 27 1935. Benzyl benzoate, bromoform, ephedra, the enzymes, the toxins, antitoxins, serums, vaccines and the specific arsenicals were dealt with as instances of the up to date nature of the contents of the Codex. The standards for surgical dressings of the Codex have served a useful purpose in connection with National Health Insurance—ANON *Drug Circ*, 122 (1935), 298 (T G W)

Prescription Compounding The third in a series of papers dealing with prescription compounding. The author discusses the lack of uniformity when a prescription is filled by different people as one of the reasons for physicians dispensing. Physicians dispense proprietaries because they are visited daily by detail men, the moral of which is to do your own detail work. The author does not believe that everything done in a prescription room should be visible by the public any more than that the place should be entirely closed, and he gives reasons for his belief. In his opinion a successful prescription pharmacy cannot be run by one man alone because when a man works at a prescription he should not be interrupted. More than twenty prescriptions are

given Difficulties are discussed and methods for compounding given—J LEON LASCOFF *J Am Pharm Assoc*, 24 (1935) 232 (Z M C)

Prescription Departments—Note on Open The author reports that a number of physicians interviewed were unanimous in their disapproval of a department in which it was possible to see the different ingredients that enter into the finished prescription. Next to seeing the ingredients the doctors objected to the tendency toward self-medication. If the patient sees a poison label unwarranted fear is engendered. If a prescription has to be tried a second time the patient may think the pharmacist is lacking in ability or is careless. As an alternative the author suggests a visible manufacturing department—J N SILSBY *J Am Pharm Assoc*, 24 (1935), 133 (Z M C)

Professional Outlook In spite of the fact that the public appreciation of pharmacy has slumped, the author is optimistic because of an inherent feeling that pharmacy is an essential and public health profession—L M KANTNER *J Am Pharm Assoc*, 24 (1935) 134 (Z M C)

Publicity—Furthering Pharmaceutical The author believes that the only way to convince the public that skill is used in filling prescriptions is to show what is done. A prescription counter that can be seen has an educating value. There is an increasing inclination to classify retail drug stores as 'merchandising establishments'. Opening the prescription department will show the processes of compounding and manufacturing. It may tend to curtail dispensing by physicians. There seems to be no reason why some part of the department should not be out of sight in order to permit privacy in working out dispensing problems. Untidy prescription departments would have to be cleaned up. A glass partition should be used to shut out conversation in the drug store proper from interference with work. That the drug store is still a *drug store* needs emphasis—W BRUCE PHILIP *J Am Pharm Assoc* 24 (1935) 224 (Z M C)

PHARMACOLOGY TOXICOLOGY AND THERAPEUTICS

PHARMACOLOGY

Acacia—Effect of Intravenous Injections of, on Physio-Chemical Properties of Blood The hemoglobin % and cell count decrease with the dilution of the blood following injections of acacia. The oxygen content of the blood falls to a more marked degree. This is probably due to a coating of the erythrocytes with acacia hindering normal cell respiration—A CHRISTIE N M PHATAK and M B OLNEY *Proc Soc Exptl Biol Med* 32 (1935), 670 (A E M)

Aconitum Napellus—Extract of Chemical Composition and Physiological Assay of Aconite. The exact nature of the principles contained in the drug is not established with certainty although crystalline aconitine is accepted as the active principle. By progressive hydrolysis of crystalline aconitine there is obtained first, benzoyleaconine and acetic acid and then benzoic acid and aconine. Aconitine is combined in the plant with aconitic acid, which is related to citric acid. Because the alkaloid easily undergoes hydrolysis to form products much less toxic than aconitine one can easily see how the toxicity of the drug can vary widely, while the chemical determination may not reveal the change. These facts necessitate a physiological assay for the drug and its preparations. In addition to the uncertain chemical status of the drug geologic and climatic factors modify considerably the therapeutic value of the drug. A comparison is made of the various physiological assays proposed from time to time. The method developed by Goris is used in this paper. The determination of the physiological activity of a dry extract of aconite containing about 0.5 per cent alkaloids soluble in ether is made in the following manner: the dry extract is dissolved in 25 per cent alcohol to obtain a tincture and this is then diluted just before use to contain about 0.05 per cent alkaloids. A volume such as will contain approximately 7 units of aconitine is then injected. Thus for a 375 Gm pig 375×0.00000007 or 0.00002625 Gm is used and the tincture is diluted with physiological salt solution till each cubic centimeter represents 0.00002625 Gm of alkaloids. If the animal does not die within six hours the dose is increased to 8 units etc. until death is produced. A new animal being used each time. This dose is then injected into several animals and the exact value in units determined. Two out of three animals must die within the time limit. For the particular sample assayed the value was found to be 10 units. The same drug from which the above extract was prepared was then percolated to prepare a tincture. By a similar procedure its value was found to be 10 units. The following

conclusion is then drawn the preparation of a dry extract, if the temperature is not allowed to go above 40° C, does not alter the alkaloidal strength of the preparation more than the preparation of a tincture by simple percolation A sample of our extract, shown chemically to contain 0.485 per cent alkaloids soluble in ether, was sent to Professor Tiffeneau for assay The results of his determinations when calculated to toxicity units also gave a value of 10 units By a comparison of the M L D of the tincture prepared and of crystalline aconitine, it is calculated that 65 per cent of the total alkaloids contained in the tincture was aconitine A comparison of this method with that of the U S P X and of the Spanish Phar is made —R FREUDWEILER *Pharm Acta Helv*, 10 (1935), 51 (M F W D)

6-Alkyl-Meta-Cresols—Oral Toxicity of The toxicity to rats upon oral administration of a complete series of 6 alkyl meta cresols from meta cresol through 6 decyl meta cresol was determined From a comparative study of the toxicity of 6 hexyl meta cresol with hexylresorcinol in animals and in man, the authors conclude that the former substance is no more toxic to man than hexylresorcinol and has been given orally to 100 individuals in doses up to 4.2 cc without symptoms or complaints —HAROLD W BROWN and PAUL D LAMSON *J Pharmacol & Exper Therap*, 53 (1935), 264 (H B H)

Alpha-Dinitrophenol—Some Effects of, on Pregnancy in White Rat Doses of 20 mg per Kg body weight given twice daily did not affect the pregnant rats in any way with the only exception, that the mortality of the young during the nursing period was increased —L M R WULFF, L A EMGE and F BRAVO *Proc Soc Exptl Biol Med*, 32 (1935), 678 (A E M)

Amidopyrine Inhibition of Leucogenic Activity in Rabbit by Certain Cyclic Compounds Rabbits respond readily with leucocytosis to treatment with nucleic acid Amidopyrine given for 18 days by mouth prevents such response Antipyrene, phenylhydrazine hydrochloride, o-quinone and catechol have the same effect Alpha dinitrophenol produces an initial stimulation followed by inhibition —DAVID R CLIMENKO *Proc Soc Exptl Biol Med*, 32 (1935), 823 (A C M)

Anesthetics, Local—Testing of, by Sciatic Nerve Block in Guinea Pig Sciatic nerve block has been added to the quantitative testing of local anesthetics on the intact and untreated guinea pig and the technique of the method is given Optimum injections were 0.2 cc in volume and analgesia was determined by light exploratory pinches of the skin Determinations were made on the following local anesthetics 1 dimethylamino 2 dimethylaminoethyl-2-butanol (alpyne) (I), γ -diethylaminopropyl ester of cinnamic acid (apothesine) (II), sulphate of γ -di-butylaminopropyl ester of *p* amino benzyl alcohol (hutyn) (III), 2,2,6 trimethyl 4 piperidinol benzoate (β Eucaine) (IV), procaine (novocaine) (V), 2 butoxy-*N*-(β dimethylaminoethyl) cinchonnamide (nupercaine) (VI) and 4 dimethyl amino 3 methyl-2 butanol (tutocaine) (VII) The relative durations of sciatic block at the concentrations 0.5, 1.0 and 2% were, respectively I 15, 12, 0.9, II 2.6, 1.4, 1.2, IV 18, 1.0, 1.5, III 5.6, 2.7, 2.0, VII 3.4, 1.9, 1.3, in terms of the figures obtained at the same concentrations with V taken as unity All save VI yielded results that were uncomplicated at these concentrations by local systemic or toxic effects The addition of 1:20,000 epinephrine to approximately threshold concentration of V and VII prolonged the analgesia about 10 and 24 times, respectively The advantages of the method are the small quantity of sample required, the distance of the area of cutaneous analgesia from the site of injection the fact that analgesia is complete in 1-3 minutes after injection and that the potency is measured by the duration of cutaneous analgesia The accuracy of the method is gaged by the ratios of the probable errors to their respective mean values the mean of 39 such ratios is 6.5% of the average periods of analgesia ranging from 10-200 minutes —L F SHACKELL *Anesthesia and Analgesia*, 14 (1935), 20, through *Squibb Abstract Bull*, 8 (1935), A-386

ApioI—Pharmacologic Tests of Slow intravenous injection of crystalline apioI (0.1-0.2 Gm per Kg) or liquid apioI, yellow or green (0.1 or 0.2 cc per Kg) in chloralosed dogs always caused marked hypotension and bradycardia, diminished the amplitude of auricular contractions and slowed up the ventricular beats Vagus section at the neck suppressed these reactions and a new injection of apioI had practically no effect on auricular or ventricular contractions or on arterial pressure Thus the effects of apioI were due to its action on the pneumogastric center However, the toxic effects occurred regardless of vagus section and death ensued due to heart failure Tests on suitable samples by the bromination method showed the following apioI titer for the various kinds crystalline (Merck) 96% crystalline (Rhône Poulenc) 75%, liquid

green 47% and liquid yellow 48% while the corresponding mortal doses in Gm per Kg intra venously in dogs were 0.5-0.75, 1-1.5, 1.8-2.2 and 0.25-0.40, respectively. Thus there was no close parallelism between theoretical apiol content and toxicity. Perhaps the chemical treatment for changing green apiol to yellow apiol gave rise to isomers that were more toxic than crystalline apiol.—F. MERCIER and L. VIGNOLI. *Compt rend soc biol*, 118 (1935) 170, through *Squibb Abstract Bull*, 8 (1935), A 420.

Apomorphine—Action of, upon Small Intestine in Non-anesthetized Dogs. Apomorphine momentarily decreases the general tonus of the ileum and jejunum. Large doses increase the tonus. It may increase the peristaltic activity and at the same time decrease the tonus.—CHARLES M. GRUBER and JOHN T. BRUNDAGE. *Proc Soc Exptl Biol Med*, 32 (1935), 863.

(A E M)

Aromatic Acids—Body Temperature Changes Produced by Sodium Salts of Some. Sodium 3,5-dinitrosalicylate injected intramuscularly into pigeons and rats causes a decrease of body temperature of 2-4°. Sodium 3,5-dinitrobenzoate shows the same effect but less marked. Animals treated with antipyrine, sodium salicylate and benzoate showed variations of less than 2°.—R. K. BREWER and M. S. DOOLEY. *Proc Soc Exptl Biol Med*, 32 (1935) 778.

(A E M)

Ascorbic Acid—Influence of, on Sensitization of Guinea Pigs to Neoarsphenamine. Ascorbic acid prevents sensitization to neoarsphenamine. The minimum dose is decidedly higher than that which protects against scurvy.—M. B. SULZBERGER and B. L. OSER. *Proc Soc Exptl Biol Med*, 32 (1935) 716.

(A E M)

Barbiturates—Sex Difference in White Rat in Tolerance to Certain. The female rat is more sensitive than the male for amylal, nembutal, evipan, pernooton and hebaral or oral. No difference was found with barbital and phenobarbital.—H. G. O. HOLCK and M. A. KANAN. *Proc Soc Exptl Biol Med*, 32 (1935) 700.

(A E M)

Caffeine Per Se and Caffeine Beverage—Effect of, on Reaction Time in Young Adults. The effect of coffee and of caffeine was studied upon the reaction time of ten subjects. It was found that coffee containing an equivalent amount of caffeine produced parallel results to caffeine administered in capsules but to a lesser degree in most individuals. Twenty-four hours after the administration of caffeine either as such or in the form of coffee in amounts of from 2.9 to 5.6 mg X Kg, no significant effect could be noted upon the reaction time.—RALPH H. CHENEY. *J Pharmacol & Exper Therap*, 53 (1935) 304.

(H B H)

Camphors and Diketone-Camphanes—Degradation of, in Animals. From the urine of dogs poisoned with camphor, Asahuna and Ishidate isolated the following oxy camphors:

3 Oxy-camphor

5 Oxy camphor

Cis π oxy-camphorTrans π oxy-camphor

According to Tamura such degradation of camphor in animals that is their oxidation is important pharmacologically. There is a positive inotropic reaction on normal frog hearts but

the reaction is not evident at the time of application, but only after a lapse of time. This fact explains the formation of potent products of metabolism of camphor. Dilute solutions are not active immediately after application. The pharmacological tests made of pure oxy camphor have so far no support in the theory given by Tamura. The same holds true for the higher oxidizable substances (aldehydes, acids, ketones). Vita Camphor (a mixture of 5 oxy camphor and oxo camphor) and oxo-camphor in a higher grade of purity have no cardiac reaction. A cardiac stimulation in frog hearts, according to Takebe, is possible due to 10 oxy camphor. But 10 oxy camphor (1), has not been found in the urine. The crude mixture of oxy camphor on the

or

addition of potassium hydroxide and on great dilution shows a typical camphor effect. With a 1:20,000 solution the pulse beat is fast and then gradually sinks. With bisulphate of lye the free vita camphor shows weak but constant cardiac reactions; this fact is not true when using synthetic products. These results led to more search of degradation products of camphor in urine. Boiling *p*-diketone camphor with chromium trioxide then with oxygen and alkali, finally with toluene, *p*-nitro benzoyl chloride and pyridine, a quantity of nitrobenzoates with a melting point of 120.5–122° was obtained. Upon analysis oxy-4-camphor nitro benzoate was found to be the product of the reaction. If potassium permanganate were used in place of oxygen the result would be a material of the formula $\text{C}_{10}\text{H}_{10}\text{O}$ with a melting point of 131–132.5°, which may produce more degradation products. It is evident that more products of metabolism of camphor can be found in urine. There is a transition of camphor ring to cyclo camphane ring in animals. *p*-Diketone camphane and cyclo camphane both form into oxy-cyclo camphane. Both acids have the same formula $\text{C}_{10}\text{H}_{10}\text{O}_4$, melting point acidity crystallization fashion and semi-carbazones — F. REINARTZ, W. ZANKE and M. KÜRSCHGEN, *Ber* 68 (1935), 310 (G. B.)

Cinchona Alkaloids—Value of, in Pneumonia. Miscellaneous Alkaloids and Some Hydrocupreine Ethers. This paper is a preliminary study of a number of naturally occurring cinchona alkaloids, their hydrogenated derivatives and some artificially prepared alkaloids with reference to their pneumococcal activity, toxicity and protective ability. Hydroxyethylhydrocupreine, an alkaloid prepared by the writers, proved to be far less toxic to mice than optochin, and was highly efficient in protecting them against pneumococcal infection — C. L. BUTLER, W. L. NELSON, A. G. RENFREW and L. H. CRETCHER, *J. Am. Chem. Soc.* 57 (1935), 575 (E. B. S.)

Diodotyrosin—In Vivo Action of. I. Diuretic Action. Diodotyrosin was shown to be an extra renal diuretic in rabbits. The German abstract in the *J. Ph. Soc. Japan* should be consulted for details of experimental conditions and results — A. OGATA and T. TANAKA, *J. Pharm. Soc. Japan* 55 (1935), 14 to 18 (R. E. K.)

Ephedrine after Digitalis—Cardiac Irregularities Produced by. The authors employed dogs and administered ephedrine and digitalis intravenously, studying the effects upon the heart by means of electrocardiographic tracings. It was found that digitalis greatly prolonged the duration of arrhythmias produced by ephedrine; in some instances cardiac irregularities were brought about by the simultaneous administration of both drugs which had not occurred when either drug was used singularly. Digitalis tended to increase the number of ventricular irregularities due to ephedrine. No fatalities were recorded from the use of these ephedrine digitalis combinations in amounts allowing of clinical comparison although weakness and prostration and arrhythmias of a serious nature were observed — M. H. SEEVERA and W. J. MEEK, *J. Pharmacol. & Exper. Therap.*, 53 (1935), 295 (H. B. H.)

Ergot Alkaloids—Effect of, on the Uterus. The authors review the use of ergot including a test for determining the biological potency of ergot and its various constituents by determinations of uterine motility of human patients from the sixth–eighth post partum day. A new substance, water soluble and representing 10% of the crude extract was isolated from ergot, sepa-

rated from an active powder that contained all the activity of the original ergot. Separation of the alkaloids left the oxytocic activity in the non alkaloid fraction. Since the active fraction was not alkaloidal, the human uterine method was used to determine activity. The new active principle is soluble in most hydrophylic solvents and relatively stable to heat, is agreeable and palatable, the dose is small and may be dissolved in 3 cc. or less of fluid and produces no gastrointestinal or other undesirable effects. It does not affect the pulse or blood pressure and when given orally the response is usually obtained in 6-15 minutes. The whole curve is characteristic of a good response obtained from an active ergot preparation. No general response appears after the use of pituitrin. The usual dosage is 3 mg. in solid form, capsules or solutions and uniform uterine motility and tone which persists for 3-4 hours are obtained. No evidence of undesirable reactions has been noted in doses 3-4 times the effective one. The authors conclude that clinically, the new principle is suitable for administration whenever the oxytocic activity of ergot is desirable. The new active principle was used in over 100 post partum patients, giving a good characteristic response while the active alkaloids in ergot, ergotamine, ergotoxine and sensibamine, given to patients orally in 3 mg. doses gave no uterine responses within an hour.—M. C. DAVIS *et al.* *Am J Obstet Gynecol*, 29 (1935) 155, through *Squibb Abstract Bull*, 8 (1935) A 327

Eserine and Acetylcholine—Effects of, on Gastro-intestinal Motility in Normal Dogs Dogs were injected during ether anesthesia intramuscularly with eserine and eserine plus acetylcholine. One mg. of eserine or less did not regularly produce peristalsis of stomach, ileum and colon. When 0.025 mg. of acetylcholine was added peristalsis resulted almost instantly. Intramuscular injections of larger amounts, 2-3 mg. of eserine induced general intestinal motility but undesirable by effects also.—R. FRANK L. ZIMMERMAN and H. NECHELES *Proc Soc Exptl Biol Med*, 32 (1935), 686 (A E M)

Galinsoga—Pharmacology of Report is made of experiments undertaken to extend our knowledge of the pharmacology of Galinsoga and to investigate the oxygen consumption by tissues. One and two per cent infusions caused an increase in oxygen consumption by heart tissue but it was not proportional to concentration. The principle or principles are apparently not extracted with cold water and they seem to be destroyed as the infusion ages. Inulin, levulose and dextrose have little influence on oxygen consumption and saponin causes a slight inhibition. Infusion of digitalis seems to contain a principle which causes an increase in oxygen consumption. These experiments suggest the possibility of using a micro respirometer for a number of investigations.—M. A. YAVORSKY and E. C. REIF *J Am Pharm Assoc* 24 (1935), 108 (Z M C)

Insulin Preparations—Evaluation of A review of several physiological methods and one chemical method of evaluating insulin. The chemical method is based upon the fact that insulin increases the concentration of copper oxide reducing substances in the urine.—O. KAUSCH *Pharm Ztg*, 80 (1935), 246 (G E C)

Liver—Anti-anemia Potency of, after Gastrectomy in Swine The anti-anemic potency of the liver becomes progressively depleted after gastrectomy.—L. GOODMAN, A. J. GEIGER and L. N. CLAIBORN *Proc Soc Exptl Biol Med*, 32 (1935), 810 (A E M)

Parasympathetic Drugs—Intestinal Motor Inhibition by Strips from different parts of the intestinal tract contracted by acetylcholine or physostigmine are relaxed by pilocarpine. Contraction produced by pilocarpine is reversed by acetylcholine only in a minority of the trials.—F. D. McCREA and DONALD F. MARION *Proc Soc Exptl Biol Med* 32 (1935) 876 (A E M)

Phosphated Iodotannic Syrup—Antirachitic Action of The iodotannic syrup of the French Pharmacopœia does not attenuate the antirachitic efficacy of even minimal effective doses of calcium hydrogen phosphate. The authors believe that the antirachitic action attributed to iodotannic combinations is nil provided that free iodine is not present in the preparation. Phosphated iodotannic syrup proved to be very efficacious as an antirachitic preparation.—R. GALLIER *Bull sci pharmacol* 42 (1935) 31 (C T I)

Phosphorus—Peculiar Action of, in Treatment of Rickets White phosphorus administered in a warm 1% oil solution to white rats, deprived of vitamin D and receiving a large excess of calcium as compared to phosphorus exhibited no rachitic action. The oil of almonds and apricots used as solvent were tested individually, and showed no effect.—R. LECOQ and R. GALLIER *J pharm chim* 21 (1935) 211 (M M 7)

Quinine, Quinidine, Hydroquinidine and Hydrocinchonidine—Toxicity of, in Guinea Pig The lethal dose for about 50% of the animals used in the test is for quinine 0.6 mg. mol. per Kg., for quinidine 0.4, for hydroquinidine 0.4 and for hydrocinchonidine 0.7—W. T. DAWSON and H. P. HARMS *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 595 (A. E. M.)

Rabies—Experimental, in White Mice and Attempted Chemotherapy II Plasmochin merthiolate, metaphen, bismuth violet, iodobismutol, bismarsen, tryparsamide, silver arsphenamine, Bayer 205, ethylhydrocupreine hydrochloride (optochin), pyridium, sodium arsinitate (atovyl), nicotain and sparteine sulphate were used as treatment for rabies in mice with none showing therapeutic value—ANSON HOYT, ROY T. FISK and CLINTON H. THIENES *J. Inf. Dis.*, 56 (1935), 21 (A. H. B.)

Sedatives Types, Uses and Dangers The types of sedatives are those which manifest their major effect in the mitigation of discomfort or pain arising on a bodily basis, e. g., morphine, codeine, acetylsalicylic acid, sodium salicylate, acetanilide, *p*-acetophenetide and amidopyrine, those which tend to reduce excessive degrees of muscular activity not associated with pain and which do not, in the usual dosage, produce sleep, e. g., 5-ethyl-5-phenyl barbituric acid (luminal), hyoscine, hydrobromide and stramonium, and those effective in controlling states of excessive mental tension which in the proper dose, will produce sleep, e. g., codeine sulphate, the bromides, chloral hydrate, paraldehyde, alcohol and the numerous barbituric acid derivatives. Sedatives should not be used in conditions of acute intra-abdominal pathology, in which the administration of a sedative might mask the signs of the disease, and the question should be carefully considered in cases of neuroses in which somatic complaints are prominent. The choice of sedative depends upon the indications. As a class the sedative drugs act as central nervous system depressants. The chief dangers from sedatives result from their temporary use in excessive amounts, their use over too long periods of time and their administration in an unfavorable milieu peculiar to the individual, e. g., allergic and hypersensitivity reactions and habituation to the drug—G. H. ALEXANDER *Am. J. Nursing* 35 (1935), 222 through *Squibb Abstract Bull.*, 8 (1935), A-449

Sodium Amytal—Effects of, on Erythrocyte Count following Hemorrhage The capillary and venous blood in the dog is immediately diluted after a single hemorrhage performed under local anesthesia. The dilution is absent when the hemorrhage is performed under general anesthesia by intravenous sodium amytal. There may even be a concentration of blood. As soon as the anesthesia wears off dilution promptly appears—R. ELMAN, D. O. WEINER and W. H. COLE *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 793 (A. E. M.)

Squill—Bioassay of Powders of The present study reveals the method of preparation, of preservation and of standardization and also the stability of a standard squill powder. The standard is prepared by placing cut scales of a composite lot of squill on a mincing plate and dried by (1) keeping the drug in a hot air oven at 60° for three days or (2) in the open at 25–30° for a period of seven days. In the course of desiccation the drug should be mixed frequently. The powder is passed next through a No. 45 sieve, dried for several hours at 60° and then sealed in ampuls. A powder containing 4–5% moisture is stable for at least one year. Drying squill by heaping it in a pile and not stirring or mixing results in a fermentation which causes a partial destruction of the glycosides. The method of assay is carried out on the dog (cf. *Year Book, Am. Pharm. Assoc.*, 22 (1933) 131). The authors propose that the official powder have a M. L. D. of 40 mg./Kg. of dog as determined by the above mentioned assay procedure—M. MASCRE, J. LÉVI and R. COHEN *Bull. sci. pharmacol.* 42 (1935) 66 (C. T. I.)

Thallium—Action of, in Experimental Animals No support could be found to the claims that thallium intoxication is characterized by alterations of the endocrine function—A. J. COX, JR., and E. B. RODGERSON *Proc. Soc. Exptl. Biol. Med.* 32 (1935), 653 (A. E. M.)

Thioaurates—Contribution to Physiologic Testing of Aurothiosulphates of sodium and calcium, calcium aurothioglucose, aurothiopropansulphonate of sodium, aurothiomalate of sodium and aurothiolactate of sodium were injected into guinea pigs and rabbits. After 48 hours the animals were sacrificed and the different amounts of compounds were recovered from the various organs. An oil solution of the quinine salts is retained for the most part, in the muscles in the area injected and distinct local reaction is produced. This reaction is much less with the other compounds, and no noticeable amounts were retained in the muscles. If the fatty tissue or bones did not retain most of the metal compound then the uterus or placenta was found to be rich in the compound. The metal accumulates especially in the liver, kidney and spleen. Strong doses usually brought

about a larger retention of metal in the kidney—M M PICON *J pharm chim* 21 (1935), 215 (M M Z)

Thymus and Pineal Extracts—Biological Effects of Active Thymus extracts produced acceleration in growth and development which was accelerated in each succeeding generation. Removal of the thymus gland resulted in retardation of growth and development of the offspring, even in the second generation of rats and this retardation was not apparent in the offspring of thymectomized rats when the parents had been injected with thymus extract or subjected to thymus transplants. The author assumes from the above that the active principle in thymus extract is a hormone. In a study of pineal extracts two were found to produce dwarfism in variably when injected intra-peritoneally into white rats but the same step like progression was not found. Dwarfism seemed no more marked in the 4th generation than in the 3rd—A M HANSON *Proc Staff Meetings Mayo Clinic*, 10 (1935), 113, through *Squibb Abstract Bull*, 8 (1935), A-453

Vitamin C—Influence of, on Development of Skin Sensitivity to Neoarsphenamine in Guinea Pig Skin sensitivity is not developed in animals suffering from subacute scurvy. Dextrose seems to have a protective effect—C W CHAPMAN and C A MORRELL *Proc Soc Exptl Biol Med*, 32 (1935) 813 (A E M)

TOXICOLOGY

Balsam of Peru—Hypersensitivity of Skin to It is estimated that 2% of the individuals who have never used any ointments have a skin supersensitive to Peru balsam and the numerous preparations containing this balsam while 5 times as many are hypersensitive if they have previously used various ointments. This hypersensitivity which is characterized by eczema etc is absolutely specific. A patch test is advised before the use of Peru balsam ointments, especially where the individual has been undergoing prolonged treatment or where a chronic eczema is present—W ENGLEHARDT *Munch med Wochschr*, 82 (1935) 256 through *Squibb Abstract Bull* 8 (1935), A 319

Boric Acid-Containing Fat-Reducers Two preparations of the urea-boric acid type, although labeled as harmless were found to produce severe pains in the occiput, stomachache and nausea. Strict supervision of the sale of boric acid containing reducing agents is recommended. Completely harmless active substitutes for the above will be discussed in a future report—SCHENK *Pharm Ztg* 80 (1935) 136 (G E C)

Dinitrophenol—Case of Poisoning by, with Recovery A case report of an 18 year-old girl who had taken 24 reducing capsules with suicidal intent. The patient's face was flushed, the respiration rate was 38 to 40 per minute, rapid and short, pulse 144 and the temperature was 103.4° F. Routine gastric lavage was done with a 5% solution of sodium bicarbonate. The symptoms being those associated with an overdose of alpha dinitrophenol the patient was placed in an ice pack in order to bring down the temperature. This was repeated whenever the temperature went over 101° F. Oxygen was administered at intervals during the first evening and 500 cc of dextrose was administered intravenously. The patient slept at intervals during the first night and the next night she complained of being hungry but vomited after taking some food. Her condition was much improved the second day. She took fluids freely, retained them and felt very much better. Recovery continued uneventfully and the patient was discharged on the third day. The patient in describing her symptoms afterward stated that during the entire time she felt as if she were on fire. At no time was consciousness lost and there was little or no pain evident during her stay at the hospital. Dinitrophenol was found in the gastric contents on laboratory examination—J C GEIGER *J Am Med Assoc* 104 (1935) 915 (M R THOMPSON)

Gold—Toxicity of Injections of After injections there are no warning symptoms until some days after 11 injections when dermatitis and very intense irritation and slight ulceration of the mouth occur. These symptoms although no further injections were made failed to clear up entirely. Further the rheumatism for which these treatments were administered failed to show any improvement—G HOLMES *Brit Med J* 1 (1935) 58 (W H H)

Mercury Bichloride—Treatment of Poisoning by While there is as yet no known specific antidote for corrosive sublimate poisoning W B Porter and C E Simons (*Amer J Med Sci* 188 (Sept 1934) 375) report a series of forty six cases in which some measure of success resulted

from a therapeutic scheme comprising gastric lavage and colonic irrigation by a solution of sodium bicarbonate and an internal administration of the salt in a dosage sufficient to maintain the urine alkaline to litmus. There were only three deaths. For the gastric lavage a saturated solution was used at a temperature of 100° F, repeated every 12 hours for the first five days, and continued still longer if the washings contained mercury. An intravenous injection of 500 cc of a 5 per cent solution was given after the lavage and repeated if vomiting persisted. A colonic irrigation of 5 per cent solution was given daily.—*Brit Med J*, 3868 (1935), 400b (W H H)

Methyl Chloride Poisoning The symptoms and degree of poisoning are thoroughly discussed along with the citation of numerous cases and their treatments.—C A BIRCH *Lancet*, 228 (1935), 259 (W H H)

Methylene Blue—Therapeutic Use of, in Phenol Poisoning The case is reported of a patient apparently in distress as a result of having drunk phenol. The patient recovered following successive aspiration of the stomach and lavage with saline, diluted egg albumin and 50% alcohol, respectively, administration of caffeine and adrenaline as stimulants, intravenous injection of glucose and saline, and the intravenous injection of 40 cc of a 1% solution of methylene blue. It is suggested that the methylene blue may have influenced the favorable outcome.—W M SHEPPE *Military Surgeon* 76 (1935), 30, through *Squibb Abstract Bull*, 8 (1935), A-229

Nitro Compounds—Toxicity of A review of the toxic phenomena which have been observed experimentally and clinically by numerous authors upon the use of 2,4 dinitrophenol and o cresol and similar dinitro compounds. Up to the present time, six deaths have been reported as due directly to the use of 2,4-dinitrophenol for reducing purposes. The British Pharmacopœia has recently added dinitrophenols, dinitrocresols and preparations containing these to its lists of poisons.—H STRAUB *Altn Wochschr*, 14 (1935) 185 through *Squibb Abstract Bull*, 8 (1935) A 367

Phenol—Dermatitis Due to In a case of dermatitis in which the hands of an interne were involved in a vesiculo pustular, erythematous eruption, treatment with an ointment containing 2 Gm crude tar, 2 Gm zinc oxide and 26 Gm petrolatum improved the condition of the left hand greatly during twenty-four hours. Treatment of the right hand with phenyl mercuric nitrate (I), 1 1500 jelly was followed by a marked vesicular reaction. Since previous eruptions were precipitated in the dissecting room and in the operating room the conclusion was drawn that contact dermatitis existed. Treatment of the left hand with the tar ointment and the right hand with the boric acid compresses was followed by marked improvement, but a skin test with I was markedly positive. Various dilutions of phenol in aqueous solution from 1 100,000 to 1 1500 were applied to the arm and patch tests were made with the disodium salt of 2,7-dibromo 4 hydroxymercurofluorescein (mereurochrome) with negative results. Patch tests with phenol containing vaseline were positive. Recurrences of the dermatitis followed on two occasions when phenol was used.—L HOLANDER *Urol Cutan Rev*, 39 (1935) 165, through *Squibb Abstract Bull* 8 (1935), A 369

Poison Cases—Concerning Important Of 372 cases appearing before the Gerichtlichen-Chemischen Institute of Budapest in criminal affairs in 1934, 85 dealt with new and exhumed cadavers, 32 drugs, 18 food residues and 237 different objects of examination. Chemical examination in 178 cases gave positive results including 35 cadavers, 27 drugs, 7 food residues and 109 different bits of evidence. The cadavers studied showed the following: arsenic 15, chromium 1, zinc 1, bromine 1, iodine 1, alcohol 2, oxalic acid 1, morphine 3, cocaine 1, atropine 1, quinine 1, pyramidon 1, pyramidon and veronal 1, evipan 1, veronal 2 and carbon monoxide 1. Special poison cases are discussed.—R FRIDL *Pharm Monatsh*, 16 (1935) 31-32 (H M B)

Poisonings—Native, in the Dutch Indies Of poisonings in the Dutch Indies, 55% are by arsenic or its compounds, and 9% by decoctions of plants containing alkaloids, saponins, glucosides, toxalbumins, etc. Potassium cyanide is another frequent source of poisonings.—C J BLOCK *Aan P van der Wielen* (1934), 139-147 through *Chimie & Industrie*, 33 (1935) 626 (A P-C)

Sodium Nitrite—Value of, as Antidote to Hydrogen Sulphide Sodium nitrite exerts a marked preventive and curative effect on hydrogen sulphide poisoning when administered either before or after the hydrogen sulphide. The antidotal action, demonstrated in mice, is due to the production of methemoglobin which fixes the toxic substance.—V KARRASSIK and V CHELOKHANOWA *Compt rend soc biol* 118 (1935) 23, through *Squibb Abstract Bull*, 8 (1935) A-435

Strychnine—Poisoning of Children by The chief source of strychnine poisoning in children was from tablets containing aloin 0.5 gr and extract of belladonna $\frac{1}{16}$ gr, strychnine $\frac{1}{4}$ gr and extract of cascara sagrada 0.5 gr. Since there were 35 cases of strychnine poisoning in children reported from 1919 to 1933 in Toronto, and 75 fatal poisonings with strychnine in New York State during 1925–1932, the authors conclude that it would be advisable to remove strychnine from the formulas of such tablets.—J. R. ROSS and A. BROWN *Can Med Assoc J*, 32 (1935) 282 through *Squibb Abstract Bull* 8 (1935) A-451

THERAPEUTICS

Acetylcholine—Value of, in Ophthalmology J. Francois (*Nederl Tijdschr v Geneesk* (Dec 1934), 5632) states that numerous ophthalmologists have emphasized the value of the basal dilator acetylcholine in obstruction of the central artery of the retina resulting from end arteritis or essential vascular spasm in quinine anuraurosis, optic atrophy, retrobulbar neuritis, thrombosis of the central vein of the retina, blindness due to loss of blood and chronic glaucoma. Acetylcholine may also be of value in visual disturbance caused by changes in the cerebral circulation such as scintillating scotoma, hemianopia or cerebral blindness. Considerable improvement follows intramuscular injections of acetylcholine in 20 cg doses daily.—*Brit Med J* 1 (1935) 400c (W. H. H.)

Anesthetic—New From his experience in 1200 cases E. de Meuson (*Rev Med de la Suisse Romande* (August 25 1934) 856) advocates as an anesthetic a mixture of scopalamine, eukodal and ephetonin. This is prepared by Merck in ampuls containing 0.005 Gm., 0.01 Gm. and 0.025 Gm. of each drug respectively. Ephetonin, synthetically obtained from ephedrine, is an excitant of the respiratory centre, and thus counteracts the paralyzing action of this centre of scopalamine and eukodal. On the eve of the operation 0.05 Gm. veronal is given orally and repeated three hours before the operation. Two ampuls of the anesthetic mixture are injected subcutaneously an hour and a half, and one ampul three quarters of an hour before the intervention. This anesthetic should be used prudently in cases of grave renal lesions; it is especially indicated when inhalation anesthetic might be dangerous, as in pulmonary tuberculosis and cardiac affections.—*Brit Med J* 1 (1935) 138c (W. H. H.)

Arsanilic Acid, *N*-(*p*-Dimethylaminobenzal)—Chemotherapeutic Testing of Fischl and Singer tested the therapeutic action of *N*-(*p*-dimethylaminobenzal) arsanilic acid (I) (arsenic yellow) and *N*-(2,4,6-trihydroxybenzal) arsanilic acid (II) (arsenic brown) against nagana and European recurrent fever in mice. The curative doses of I and II against nagana in Gm. per 20 Gm. of mouse intramuscularly were $\frac{1}{180}$ and $\frac{1}{200}$ respectively, and the toxic doses were $\frac{1}{60}$ and $\frac{1}{35}$ respectively, the therapeutic indexes being 1.15 and 1.4 respectively. I had no curative action against recurrent fever but the curative dose of II was $\frac{1}{50}$ and the index 1.1. No toxic dose was recorded.—Viktor Fischl and Ernst Singer *Biochem Z* 276 (1935) 277, through *Squibb Abstract Bull* 8 (1935) A-420

Chemotherapy—Biological Problems in It was found that the aromatic pentavalent arsenical and antimonial compounds are but slightly trypanocidal, a solution of about 1:1000 being required to destroy the parasites within 24 hours at 37° C. The corresponding trivalent compounds are however amazingly trypanocidal, as even when diluted a hundred million times they killed the trypanosomes within 24 hours. This is also true of the arsenobenzol compounds such as novarsenobillon. The non aromatic trivalent compounds sodium arsenite and tartar emetic likewise display considerable activity, their trypanocidal titers being respectively 1:3,200,000 and 1:6,400,000. The acridine dye acriflavine is highly trypanocidal, but Bayer 205 resembles the pentavalent arsenical compounds in exhibiting practically no trypanocidal action *in vitro*.—W. Yorke *Lancet*, 228 (1935) 191 (W. H. H.)

Copper, Colloidal—Value of, in Septicæmia. L. M. Reinhold (*These de Paris*, 1934, No 766) records ten cases of streptococcal or staphylococcal septicæmia in patients aged from 12 to 27 treated by intravenous injections of colloidal copper. The injections should be given in doses ranging from 5 to 20 cc. daily, repeated every day or every two days. These injections should be continued for four or five days after the temperature has fallen, so that the total duration of treatment is about ten days. The cases treated were acute osteomyelitis and puerperal fever.—*Brit Med J* 1 (1935), 60 (W. H. H.)

Curarine—Case of Tetanus Treated with It appears that curarine is generally accepted

as the most suitable alkaloid of its group for the use in the treatment of tetanus After the injection of curarine there is a decrease in the muscle tone and there appeared to be no undesirable effects—J S MITCHELL *Lancet*, 228 (1935), 262 (W H H)

Garlic and Its Preparations Garlic is used in affections of the respiratory tract and in hypertension A tincture prepared by extraction with 80% alcohol, or an extract prepared with a hydroalcoholic menstruum (1 1 or 1 2 with 95% alcohol) is used A juice may be prepared from 800 Gm garlic with 200 cc alcohol and 1000 cc water A solution of the garlic essence (2%) in olive oil can be used hypodermically In bronchitis, the following formula is recommended Garlic essence 0.5–2%, gomenol 10–20% a mixture of equal parts of camphor with guaiacol 5–10% olive oil to make 100 cc—ALFREDO J BANDONI *Rev farm* (Buenos Aires), 77 (1935) 25 (A E M)

Gold Salts—Value of, in Disseminated Sclerosis G Dubois-Andre (*Le Scalpel*, Oct 27 (1934), 1517) records three cases of disseminated sclerosis treated by aurothio glucose in oily suspension, when good results were obtained despite previous failures with other lines of treatment He believes that the injections act by arresting the new formation of neuroglia, thus preventing the progressive destruction of myelin and safeguarding the nerve cells and fibres from the menace of fibrotic strangulation The maximum dose is 30 cg repeated twice at an interval of ten days The initial dose is small—5 cg, injected once a week, this is repeated before a higher dose is tried and the same principle is observed throughout the course of treatment—*Brit Med J* 1 (1935), 288b (W H H)

Insulin—Value of, in Toxic Diphtheria Antitoxin intravenously and intramuscularly and dextrose intravenously and by mouth are accepted as the basis of treatment in toxic diphtheria In diphtheria the response of the body to intravenous dextrose is constantly abnormal and results in higher blood sugar findings The degree of variation is a sensitive index to the severity of the attack and serves as a reliable guide to the progress of the disease A fairly close association appears to exist between abnormalities in tolerance curves and involvements of the cardiovascular mechanism How much the former depends upon the latter it is impossible to say from this investigation Insulin does not appear to change the character of the abnormal curves nor to influence the course of the disease as judged by the fatality and complication rates—N D BEGG *Lancet* 228 (1935) 480 (W H H)

Iodine, Colloidal—Use of, in Medicines and Cosmetics The use of colloidal iodine in medicines and in cosmetics as a scalp remedy in soaps, toothpastes and creams is discussed—O E OSTBERG *Drug and Cosmetic Ind* 36 (1935) 423–424 (H M B)

Methylene Blue—Direct Action of, on Hansen Bacillus Intravenous injections of 1% methylene blue solutions in doses of 20 cc are retained by leprosy tissue and exercise a direct *in vivo* action on the Hansen bacillus which shows progressive microscopic changes characteristic of degeneration, e g, granular appearance polymorphism followed by cyanophilia A number of cases of leprosy are undergoing treatment with methylene blue solutions One case described showed progressive and rapid amelioration of the lesions, many of which were completely eliminated after 25 injections—P LEPINE and J MARKIANOS *Compt rend soc biol* 118 (1935) 9 through *Squibb Abstract Bull* 8 (1935) A-440

Oestrin—Treatment of Vulvo-Vaginitis with The main features of the treatment are (1) that it is shorter than other methods (2) it is easy of application as the drug can be given by mouth, and (3) it quickly diminishes the discharge and thereby reduces the infectivity of the patient and the risk of spreading the disease—D NABARRM and A G SIGNY *Lancet*, 228 (1935), 604 (W H H)

Ophthalmic Therapeutics A classification of substances used in daily routine for treatment of eye injuries burns, infections, etc For instance, castor oil or liquid petrolatum is used to decrease the irritation of a foreign body—or to help to remove it by floating it out Fluorescein is used for its staining properties as an aid to diagnosis as it stains only such parts of the eye surface as are denuded of their epithelium, and is of value in showing the extent of injury or ulceration Methylene blue is also used for its staining properties Substances used for their direct chemical action include 1–2% solutions of sodium bicarbonate (to neutralize acid burns) boric acid or very dilute acetic acid (in alkaline burns) and 10% neutral ammonium tartrate (in lime burns) Copying ink pencil—an aniline derivative—acts as a caustic in the eye and can be dissolved out with glycerin—or its activity may be restricted by using weak tannic acid (5%)

Antiseptics for the eye can be applied in many forms. For instance lotions, as follows: saline, boric acid, sodium bicarbonate, flavine, mercury bimiodide, zinc sulphate, potassium permanganate, drops as (a) the silver group—silver nitrate, argyrol, protargol, neoprotosil, collosol argentinum, (b) zinc sulphate, collosol zinc, (c) copper sulphate, (d) mercurochrome. Powders to be dusted inside the lids—in a very fine state of subdivision: calomel, iodoform, boric acid. Ointments such as yellow mercuric oxide, zinc oxide, staniform, neoprotosil, copper sulphate and trachomian ointment. The mydriatics such as atropine, homatropine, etc. act on the iris in such a way that the pupil tends to dilate. The myotics, eserine and pilocarpine, contract the pupil and help to reduce intraocular tension.—D. L. CHARTERS *Pharm J*, 134 (1935) 213 (W. B. B.)

Parathyroid Tetany—Treatment of. While Collip's parathormone is active in raising the level of the serum calcium and relieving the symptoms of parathyroid tetany, it is not satisfactory unless injected in large and repeated doses. It is also expensive. In most cases, therefore, it is impracticable to employ it. The intravenous administration of 10 cc. of a 10% solution of calcium chloride produces relief of symptoms in a few minutes, lasting for about a day and a half. It is an excellent emergency measure. While injecting a solution of this strength, care must be taken that none of it escapes into the subcutaneous tissue, for necrosis of tissue and ulceration may result. A good method of treatment is to present continuously to the bowel a large amount of calcium in the form of calcium chloride (150 gr. daily). In cases where this is not effective, 50 to 100 cc. of N/3 hydrochloric acid should be given to increase the absorption of calcium. This acid is given in milk in the proportion of 1 to 20 of milk.—D. CAMPBELL *Lancet* 228 (1935) 369 (W. H. H.)

Quinidine Sulphate—Evaluation of Use of, in Persistent Auricular Fibrillation. A study of 49 cases of auricular fibrillation in which 46 were classified as permanent and 3 as transient, treated with quinidine sulphate, showed that normal rhythm was restored in 35 or 71.4% of the cases. Of 33 cases with adequate follow-up notes, only 17 or 51% remained regular over 1 year. Two tenths gram of quinidine sulphate was given orally as a test dose; the following day 0.3 Gm. was administered 3 times, and each day the dose was increased 0.1 Gm. until the rhythm became regular, when the patient was placed on a maintenance dose. Rheumatic valvular disease is most resistant. A non-valvular fibrillation responds more readily, and in cases of hyperthyroidism without cardiovascular disease treated post-operatively, reversion to normal rhythm is practically invariable. Duration of fibrillation influences to some extent the likelihood of reversion; cases with a short history reverting more readily. It is doubtful whether most cases are in better health with a regular rhythm than with auricular fibrillation when the ventricular rate can be kept slow. There is no method of predicting fatal results with quinidine therapy. The presence of fibrillation and increasing years are both separate factors favoring auricular mural thrombosis. The four indications for the use of quinidine sulphate seem to be: the presence of fibrillation in an otherwise normal heart; its persistence after operation for hyperthyroidism, when the irregularity is the cause of intractable palpitation; and in certain hopeless cases where other forms of treatment have failed. Contraindications are an idiosyncrasy to quinine and a previous history of embolism, badly damaged hearts, marked cardiac hypertrophy and long-standing fibrillation, etc.—C. M. KOHN and S. A. LEVINE *Ann Internal Med*, 8 (1935) 923, through *Squibb Abstract Bull*, 8 (1935), A-447.

Strophanthin—Value of, in Angina Pectoris. E. Edens (*Munch med Woch* (Sept 14 1934) 1424) believes that angina pectoris is most commonly due to anemia of the heart following increased irritability and spasm of the coronary blood vessels. He has given strophanthin—0.3 mg. strophanthin is given daily (in severe cases twice daily) for three days with an interval of one day. The attacks became less frequent and less painful and stopped altogether in a short time. He also states that intravenous injection is better than intramuscular or oral administration.—*Brit Med J* 1 (1935) 138c (W. H. H.)

NEW REMEDIES

SYNTHETICS

Alkoxybenzamides—Substituted. N,N-Dimethyl (or diethyl) di (or -tri) methoxy (or -ethoxy) benzamides are prepared by standard processes, e.g., from the alkoxybenzoyl halides and dimethyl amine or diethyl amine. Examples are given of the preparation of *veratric acid*

dimethylamide, b_1 203° melts at 102–103°, and diethylamide, b_{12} 205°, *N,N* dimethyl 3,4,5 trimethoxybenzamide, b_{13} 218°, melts at 74°, *N,N* diethyl 3,4,5 trimethoxybenzamide, b_{13} 220–226° melts at 54°, *N,N* dimethyl 2,3 dimethoxybenzamide, b_{12} 172°, *N,N* diethyl 3 methoxy 4,5 diethoxybenzamide, b_{12} 211–212°, *N,N* diethyl 3,5 dimethoxy-4 ethoxybenzamide, b_{13} 213°. The products are of therapeutic value in the treatment of circulatory and respiratory organs — *Soc pour l'ind chim à Bâle* Ger Pat, 608,412, Jan 23, 1935 (Cl 120 16) (S W G)

Antimony Compounds—Therapeutic, Bactericidal and Antiparasitic Organic Antimony oxyacids are dissolved in solutions of salts formed by interaction of cinchona bark alkaloids such as quinine with polyhydroxy monocarboxylic acids derived from aldoses such as the gluconic acid salts of quinine, etc., and the resulting clear solution is evaporated *in vacuo* to obtain the product such as $C_9H_{10}O_{20}N Sb_2$ — WALTER KUSSMAUL (to Chemische Fabrik vorm Sandoz) U S Pat 1,991,293, Feb 12, 1935 (S W G)

Dibroluur (Society for Chemical Industry, Katwijk, Netherlands) is bromdiethylacetylurea which appears on the market in 0.5 Gm tablets — *Pharm Weekblad*, 72 (1935), 371 (E H W)

Eumarcon (Riedel de Haen, Berlin) is the sodium salt of isopropyl- β bromallyl-*N* methyl malonylureum. It is found on the market in a 10% stabilized aqueous solution used as an intravenous injection for producing partial narcosis in small operations and narcosis in operations of short duration — *Pharm Weekblad*, 72 (1935), 277 (E H W)

Picochrome—New Urinary Antiseptic Picochrome is a new water soluble azo dye consisting of orthocresyl 5,5, azo 4,6 diamino 2 picoline hydrochloride containing twenty per cent tetrabromoorthocresol. The structural formula of picochrome is given as follows

Picochrome incorporating diamino picoline, a newly discovered radicle, is a highly effective urinary antiseptic which exhibits distinct advantages in its bactericidal and bacteriostatic action. The analgesic effect on the mucous membranes of the urinary tract is particularly beneficial. Owing to its potency in high dilutions copious fluid intake may be maintained. It acts equally well in acid and alkaline urines and against *Bacillus coli*, as well as against coccus infections of the urinary tract. The drug is well tolerated by mouth intravenously and locally, even over long periods. All types of urinary infections have been treated some resulting in excellent cures but the majority being influenced with varying degrees of benefit. Although picochrome cannot be classed as the ultimate urinary antiseptic, it presents enough advantages to warrant its inclusion in our favored armamentarium against urinary infection — A RAVICH *Med Record*, 141 (1935) 343 (W H H)

Prontosil (I G Bayer) is a preparation particularly useful against the principal causes of sepsis, streptococci, staphylococci, etc. It is the hydrochloric acid salt of 4 sulphonamide-2,4 diaminobenzol. Prontosil is a reddish crystalline powder having a melting point of 247–251°. It is rather indifferent pharmacologically, relatively large doses being secreted unaltered in the urine in test animals. Beginning doses are 3–6 tablets per day each tablet weighing 0.3 Gm. Ampuls also appear on the market containing 20 cc of a 0.25% solution for intravenous injection — *Pharm Weekblad* 72 (1935) 371 (E H W)

Tannin—Difficultly Soluble Preparation of About 153 parts tannin 33 parts aluminum hydroxide and 25 parts calcium oxide or aluminum or calcium salts equivalent to them are boiled together. An almost tasteless, greenish powder is obtained which is useful as an intestinal astringent — DARMOL *Gyogyszervegyeseti Ipart és Kereskedelmi R T* Hung Pat, 111 367 Jan 2 1935 (S W G)

SPECIALTIES

Adexoline (Glaxo Laboratories London) contains vitamins A and D in high concentration and in the proportion in which they occur in cod liver oil. The vitamin A is obtained from liver oils from the codfish and the halibut. The vitamin D is calciferol G L, the pure crystalline

Antiseptics for the eye can be applied in many forms. For instance, lotions, as follows: saline boric acid, sodium bicarbonate, flavine, mercury bimodide, zinc sulphate, potassium permanganate, drops as (a) the silver group—silver nitrate, argyrol, protargol, neoprotosil, collosol argentinum, (b) zinc sulphate collosol zinc, (c) copper sulphate, (d) mercurochrome. Powders to be dusted inside the lids—in a very fine state of subdivision: calomel, iodoform, boric acid. Ointments such as yellow mercuric oxide, zinc oxide, staniform, neoprotosil, copper sulphate and trachomian ointment. The mydriatics such as atropine, homatropine, etc., act on the iris in such a way that the pupil tends to dilate. The myotics, eserine and pilocarpine contract the pupil and help to reduce intraocular tension.—D L CHARTERS *Pharm J*, 134 (1935) 213 (W B B)

Parathyroid Tetany—Treatment of. While Collip's parathormone is active in raising the level of the serum calcium and relieving the symptoms of parathyroid tetany, it is not satisfactory unless injected in large and repeated doses. It is also expensive. In most cases therefore it is impracticable to employ it. The intravenous administration of 10 cc of a 10% solution of calcium chloride produces relief of symptoms in a few minutes lasting for about a day and a half. It is an excellent emergency measure. While injecting a solution of this strength care must be taken that none of it escapes into the subcutaneous tissue for necrosis of tissue and ulceration may result. A good method of treatment is to present continuously to the bowel a large amount of calcium in the form of calcium chloride (150 gr daily). In cases where this is not effective, 50 to 100 cc of N/3 hydrochloric acid should be given to increase the absorption of calcium. This acid is given in milk in the proportion of 1 to 20 of milk.—D CAMPBELL *Lancet* 228 (1935), 369 (W H H)

Quinidine Sulphate—Evaluation of Use of, in Persistent Auricular Fibrillation. A study of 49 cases of auricular fibrillation in which 46 were classified as permanent and 3 as transient treated with quinidine sulphate showed that normal rhythm was restored in 35 or 71% of the cases. Of 33 cases with adequate follow-up notes, only 17 or 51% remained regular over 1 year. Two tenths gram of quinidine sulphate was given orally as a test dose the following day 0.3 Gm was administered 3 times and each day the dose was increased 0.1 Gm until the rhythm became regular when the patient was placed on a maintenance dose. Rheumatic valvular disease is most resistant; non valvular fibrillation responds more readily and in cases of hyperthyroidism without cardiovascular disease treated post operatively reversion to normal rhythm is practically invariable. Duration of fibrillation influences to some extent the likelihood of reversion; cases with a short history reverting more readily. It is doubtful whether most cases are in better health with a regular rhythm than with auricular fibrillation when the ventricular rate can be kept slow. There is no method of predicting fatal results with quinidine therapy. The presence of fibrillation and increasing years are both separate factors favoring auricular mural thrombosis. The four indications for the use of quinidine sulphate seem to be: the presence of fibrillation in an otherwise normal heart, its persistence after operation for hyperthyroidism, when the irregularity is the cause of intractable palpitation and in certain hopeless cases where other forms of treatment have failed. Contraindications are an idiosyncrasy to quinine and a previous history of embolism, badly damaged hearts, marked cardiac hypertrophy and long standing fibrillation, etc.—C M KOHN and S A LEVINE *Ann Internal Med* 8 (1935), 923 through *Squibb Abstract Bull*, 8 (1935) A-447

Strophanthin—Value of, in Angina Pectoris. E Edens (*Munch med Woch* (Sept 14 1934) 1424) believes that angina pectoris is most commonly due to anemia of the heart following increased irritability and spasm of the coronary blood vessels. He has given strophanthin—0.3 mg strophanthin is given daily (in severe cases twice daily) for three days with an interval of one day. The attacks became less frequent and less painful and stopped altogether in a short time. He also states that intravenous injection is better than intramuscular or oral administration.—*Brit Med J* 1 (1935) 138c (W H H)

NEW REMEDIES

SYNTHETICS

Alkoxybenzamides—Substituted. N N Dimethyl (or -diethyl) di (or tri) methoxy (or -ethoxy) benzamides are prepared by standard processes e.g. from the alkoxybenzoyl halides and dimethyl amine or diethyl amine. Examples are given of the preparation of veratric acid

dimethylamide, b_1 203°, melts at 102–103°, and diethylamide, b_1 205°, *N,N* dimethyl 3,4,5 trimethoxybenzamide, b_{13} 218°, melts at 74°, *N,N* diethyl 3,4,5 trimethoxybenzamide, b_{13} 220–226° melts at 54°, *N,N* dimethyl 2,3 dimethoxybenzamide b_{12} 172°, *N,N* diethyl-3 methoxy 4,5 diethoxybenzamide, b_1 211–212°, *N,N* diethyl 3,5 dimethoxy-4 ethoxybenzamide, b_{13} 213° The products are of therapeutic value in the treatment of circulatory and respiratory organs — *Soc pour l'ind chim à Bâle* Ger Pat, 608,412, Jan 23, 1935 (Cl 12o 16) (S W G)

Antimony Compounds—Therapeutic, Bactericidal and Antiparasitic Organic Antimony oxyacids are dissolved in solutions of salts formed by interaction of cinchona bark alkaloids such as quinine with polyhydroxy monocarboxylic acids derived from aldoses such as the gluconic acid salts of quinine, etc., and the resulting clear solution is evaporated *in vacuo* to obtain the product such as $C_{12}H_{10}O_6N_2Sb$ —WALTER KUSSMAUL (to Chemische Fabrik vorm Sandoz) U S Pat 1,991,283, Feb 12, 1935 (S W G)

Dibroluur (Society for Chemical Industry, Katwijk, Netherlands) is bromdiethylacetyl urea, which appears on the market in 0.5 Gm tablets —*Pharm Weekblad* 72 (1935), 371 (E H W)

Eumarcon (Riedel de Haen, Berlin) is the sodium salt of isopropyl β bromallyl *N* methylmalonylureum. It is found on the market in a 10% stabilized aqueous solution used as an intravenous injection for producing partial narcosis in small operations and narcosis in operations of short duration —*Pharm Weekblad*, 72 (1935) 277 (E H W)

Picochrome—New Urinary Antiseptic Picochrome is a new water soluble azo dye consisting of orthocresyl 5,5, azo 4,6 diamino 2, picoline hydrochloride containing twenty per cent tetrabromooresol. The structural formula of picochrome is given as follows

Picochrome incorporating diamino picoline, a newly discovered radicle, is a highly effective urinary antiseptic which exhibits distinct advantages in its bactericidal and bacteristatic action. The analgesic effect on the mucous membranes of the urinary tract is particularly beneficial. Owing to its potency in high dilutions, copious fluid intake may be maintained. It acts equally well in acid and alkaline urines and against *Bacillus coli*, as well as against coccus infections of the urinary tract. The drug is well tolerated by mouth intravenously and locally even over long periods. All types of urinary infections have been treated, some resulting in excellent cures but the majority being influenced with varying degrees of benefit. Although picochrome cannot be classed as the ultimate urinary antiseptic, it presents enough advantages to warrant its inclusion in our favored armamentarium against urinary infection —A RAVICH *Med Record*, 141 (1935), 343 (W H H)

Prontosil (I G Bayer) is a preparation particularly useful against the principal causes of sepsis streptococci staphylococci, etc. It is the hydrochloric acid salt of 4-sulphonamide-2, 4-diaminobenzol. Prontosil is a reddish crystalline powder having a melting point of 247–251°. It is rather indifferent pharmacologically relatively large doses being secreted unaltered in the urine in test animals. Beginning doses are 3–6 tablets per day, each tablet weighing 0.3 Gm. Ampuls also appear on the market containing 20 cc of a 0.25% solution for intravenous injection —*Pharm Weekblad* 72 (1935) 371 (E H W)

Tannin—Difficultly Soluble Preparation of About 153 parts tannin, 33 parts aluminum hydroxide and 25 parts calcium oxide or aluminum or calcium salts equivalent to them are boiled together. An almost tasteless greenish powder is obtained which is useful as an intestinal astringent —DARMOL *Gyógyszerészeti Ipar és Kereskedelmi R T* Hung Pat, 111 367, Jan 2 1935 (S W G)

SPECIALTIES

Adexolme (Glaxo Laboratories, London) contains vitamins A and D in high concentration and in the proportion in which they occur in cod liver oil. The vitamin A is obtained from liver oils from the codfish and the halibut. the vitamin D is calciferol G L the pure crystalline

product Each cc contains 40,000 vitamin A units and 2000 vitamin D units, that is 20 times that of cod liver oil It is found on the market in vials of 8 Gm and in capsules —*Pharm Weekblad*, 72 (1935) 277 (E H W)

Aecuferrolstroop with Manganese (N V Kon Pharm Factories of Brocades & Stheeman and Pharmacia, Netherlands) contains 2 mg of manganese per tablespoon —*Pharm Weekblad*, 72 (1935) 370 (E H W)

Alleton (Riedel de Haen) is a preparation containing 12% garlic oil in chemical combination with dioxycholic acid which occurs on the market in pills Each pill contains the active ingredients of one gram of garlic The iodine and sulphur bearing oils of garlic have been recommended in intestinal derangements dyspepsia arteriosclerosis and hypertonicity The crystalized combination with dioxycholic acid has a less disagreeable odor and taste The dose is one tablet three times a day —*Pharm Weekblad*, 72 (1935), 277 (E H W)

Alloform (Curta & Co, Berlin) is an alum earth preparation used in preparing solution of aluminium acetate —*Pharm Weekblad*, 72 (1935), 277 (E H W)

Allyarsin is the alternative name for *Danarsin* which should not be confused with *Danamin* (see *J A Ph A*, Abstr Sec, 24 (1935) 40) —*Pharm Weekblad* 72 (1935), 277 (E H W)

Alpecine-Oil (Dr A Wolff Bielefeld) is a "hair-grower" made from olive oil with a lecithin emulsion This firm also manufactures Alpecine-Hairwater for washing hair —*Pharm Weekblad*, 72 (1935) 277 (E H W)

Brocanal (Curta & Co, Berlin) contains 0.025 Gm phenylethylbarbituric acid 0.4 Gm bromcalcium diethanolamine and 0.015 Gm caffeine It is used in epilepsy —*Pharm Weekblad* 72 (1935) 277 (E H W)

Cantan (Bayer Hoechst) is vitamin C Each tablet contains 0.025 Gm ascorbic acid —*Pharm Weekblad*, 72 (1935), 277 (E H W)

Coffex (Dr R & O Weil Frankfurt) is a new name for "Coffeo citrine" a mixture of acetyl salicylic acid and caffeine —*Pharm Weekblad*, 72 (1935) 277 (E H W)

Decholine (Chemical factory of Riedel-de Haen Berlin) is the legally protected name under which dehydrocholic acid in 0.25 Gm tablets and sodium dehydrocholate in 5% and 20% solution, in ampuls is found on the market It serves as a choleric and cholagogue in gall stones etc The solution is used intravenously 5-10 cc every two or three days, the tablets 1-2 tablets three times a day —*Pharm Weekblad* 72 (1935) 277 (E H W)

Diaturasa (Cera Laboratories Barcelona) is a remedy for rheumatism gout lumbago neuralgia, etc appearing on the market in four forms The liquid for injection contains according to the label, salicylic-benzo benzylic ethyl ester 40 mg benzyl morrhuate 100 mg, benzyl sulphide 10 mg camphor 10 mg, ether 50 mg, olive oil to make 1 cc The capsules contain salicylic benzo benzylic ethyl ester 100 mg benzyl morrhuate 95 mg, benzyl sulphide 5 mg, per capsule The granules contain lithium nucleotriphosphor 5 Gm methyl phenyl quinoline carbonic acid 6 Gm hexamethylenetetramine sulphosalicylic acid 6 Gm, sodium methylarsenate 25 mg tartaric acid 40 Gm, sodium bicarbonate 40 Gm, essence of peppermint essence of bananas, vanillin *q s* for 100 Gm of granules The ointment contains salicylic-benzo benzylic ethyl ester 25 Gm, terpineol 10 Gm camphor 5 Gm menthol 2 Gm, oil of juniper 1 Gm oil of sage 0.5 Gm, compound oil of hyoscyamus *q s* ad 100 Gm It is not clear just what salicylic-benzo benzylic ethyl ester and the other compounds really are —*Pharm Weekblad* 72 (1935), 370 (E H W)

Digalol (Riedel de Haen) is mentha dioxycholic acid, found on the market in 0.1 Gm tablets The adjunction "mentha" is not clear as to whether it is a menthol ester or a mixture Dioxycholic acid is used in most affections of the liver and gall bladder It is thus used in gall stones and as a laxative The dose is two tablets three times a day —*Pharm Weekblad*, 72 (1935), 277 (E H W)

Eusod (Fabrik Schering-Kahlbaum A-G Berlin) consists of synthetic aluminum sodium silicate and magnesium oxide It is recommended for heartburn It is distributed in packages of 6 and 12 tablets —*Pharm Ztg* 80 (1935) 150 (G E C)

Hydronal (I G Bayer) is aluminum hydroxide prepared by a special process whereby it is readily soluble in the acid juices of the stomach When hydronal comes in contact with the gastric juice it gelatinizes and absorbs the acid Hydronal for use as an antacid in stomach affections appears on the market in 0.5 Gm tablets —*Pharm Weekblad* 72 (1935) 371 (E H W)

Kataline (Society for Chemical Industry, Katwijk, Netherlands) is a mixture of phenacetin 0.1 Gm, dimethylamidopyrin 0.15 Gm, quinine sulphate 0.05 Gm and caffeine 0.05 Gm appearing on the market in tablet form — *Pharm Weekblad*, 72 (1935), 371 (E H W).

Lanogeen (Chemical and Pharmaceutical Factory of E. Scheurlieh, Hirschberg) is an ointment base which, like lanolin, takes up a large quantity of water. It contains cholesterol esters — *Pharm Weekblad*, 72 (1935), 277 (E H W).

Larostidin (Hoffman-La Roche and Co. A-G, Berlin) is a 4% isotonic and sterile solution of L-histidine monohydrochloride. It is used in the treatment of peptic ulcers of the gastrointestinal canal. One intramuscular injection per day for three weeks brings about disappearance of pain. The preparation is marketed in packages of 6 and 25 ampuls — *Pharm Ztg*, 80 (1935) 174 (G E C).

Lutreen (I. G. Farben) is a biologically standardized extract prepared from corpus luteum, which is found on the market in ampuls containing two rabbit units per cc. It serves in gynecological hemorrhages and in the prevention of abortion — *Pharm Weekblad*, 72 (1935), 277 (E H W).

Pelose (Schering-Kahlbaum) is a homogenous mud which absorbs considerable water and becomes very plastic. It is used as a cataplasm in rheumatic affections — *Pharm Weekblad*, 72 (1935), 277 (E H W).

Per-iodotheodural (Society for Chemical Industry, Katwijk, Netherlands) is a mixture of 30 mg of papaverine HCl and 417 mg of Calcium Salicylate with Theobromino Calcium, appearing on the market in tablet form — *Pharm Weekblad*, 72 (1935), 371 (E H W).

Proviron (Schering-Kahlbaum) is a standardized male sex hormone, of which the formula appears to be $C_{19}H_{30}O_2$. It is used as subcutaneous and intramuscular injection — *Pharm Weekblad*, 72 (1935), 277 (E H W).

Sulfigen (Anhaltisches Serum-Institut, Berlin) is a colloidal sulphur preparation with no protective colloids containing about 0.13% sulphur and 0.57% sulphur dioxide. In solution polythionic acids are formed which penetrate gelatin and tissue to a depth of 2 mm and which change into colloidal sulphur and sulphurous acid. It is used in the form of a wash for slowly granulating infected wounds, eczema, pruritis, ichthyosis and psoriasis. For use, the contents of a tube are dissolved in 0.5 liter of water, and as soon as the solution becomes cloudy and develops the characteristic odor of sulphurous acid it may be applied. It should be used at once as its activity begins to diminish within 30 minutes. It is marketed in cartons containing 5 tubes — *Pharm Ztg*, 80 (1935) 189 (G E C).

Tonicum Katwijk (Society for Chemical Industry, Katwijk, Netherlands) consists of liquid extract of kola 200, saccharum 200, aromatic spirit 90, glycerin 125, saccharus manganosus 2, tincture of nux vomica 10, sodium methylarsenate 1, sodium biphosphate 37, distilled water ad 1000. Use and dosage is left to the physician — *Pharm Weekblad*, 72 (1935) 371 (E H W).

Tonicum Noury (N. V. Nourypharma, Deventer, Netherlands) contains liquid extract of kola 20, glycerin 10, tincture nux vomica 1, sodium methylarsenate 0.1, saccharus manganosus 0.2, sodium biphosphate 3.7, corrigenda ad 100. It is directed to be used two to three times a day, one half hour before meals. 1-2 teaspoonfuls for adults and 1/2-1 teaspoonful for children — *Pharm Weekblad*, 72 (1935) 372 (E H W).

Tyronormon (Schilddrüsen Schutzzstoff) (Sächsisches Serumwerk, Dresden) is a standardized and biologically assayed antithyroidal (1 tablet = 10 aT). It is given in doses of two tablets three times a day and is used in Grave's disease and thyreotoxicosis. The diet is directed to contain no meat or fish but should contain 1-2 liters of milk — *Pharm Weekblad*, 72 (1935) 372 (E H W).

Vaccine Dr. Aman (Bayrol Chemische Fabrik, Munich). This preparation is used for the early diagnosis of cancer and malignant tumors and is prepared from staphylococci which are always present in tumors. It is supplied in ampuls containing 0.3 cc of which about 0.1 cc after previous shaking of the ampul is injected subcutaneously into the forearm. Irritation and rubbing at the point of injection is to be avoided. A malignant growth is present if after 24 hours a bright red coloration and infiltration may be seen at the point of injection — *Pharm Ztg*, 80 (1935) 212 (G E C).

BACTERIOLOGY

Antimeningococcus Serum—Notes on the Concentration and Purification of Purification of the globulin is best accomplished by fractional solution in dilute sodium chloride with from 66 to 88 per cent of the serum protein removed. Isoelectric fractionation eliminated 76 to 85 per cent zinc chloride 79 to 85 per cent, and dialysis and isoelectric fractionation 67 to 80 per cent of the serum protein. The sodium chloride method proved simplest, best for large quantities of serum and the product may be diluted without precipitation with sodium chloride solution.—PHILIP MURDICK and SOPHIA M COHEN *J Immunol*, 28 (1935), 205 (A H B)

Antityphoid Serum—New. In experiments on mice, published in *Lancet* 227 (1934), 186, it was established that antityphoid sera containing O and Vi antibodies exert two separate and distinct effects, viz (a) The Vi antibody confers protection against infection with highly virulent strains of *B typhosus* by suppressing the multiplication of the organisms. (b) The O antibody appears to be chiefly responsible for effecting the neutralization of the endotoxin of *B typhosus*. It was concluded that the efficacy of the therapeutic antityphoid serum would depend on the presence in it of both these antibodies. From the clinical trials it may be stated that some action on the toxic symptoms and on the fever was exercised by the antityphoid serum.—A FELIX *Lancet* 228 (1935) 799 (W H H)

Bacillary Dysentery—Cause of, in Infants and Children. Chemical and bacteriological data indicated that the Flexner and Sonne strains of the *Eberthella paradysenteriae* were responsible for 74% of the infectious diarrheas of children and infants. The organisms gradually disappear after the fifth day. The etiological organisms were diagnosed by titer agglutinations.—G A DENISON and G DEHOLL *J Infect Dis*, 56 (1935) 124 (A H B)

Chlorine—Bactericidal Action of. Because chlorine is one of the most widely used germicides in public health work an effort is made in this paper to determine the bacterial death rate caused by various concentrations of chlorine. There seems to be concentrations which first stimulate then inhibit, and finally in higher concentrations kill various pathogenic organisms. Exposed to 10-6 dilutions of chlorine one million bacteria were reduced 99 per cent. The results however indicate bacterial growth is just as great before as after the action of chlorine. Bacterial death, then is reversible to a certain extent and also there are zones of life dormancy after death. Many germicides cause dormancy and not death judging from the tabulations recorded in the paper.—C S MUDGE and F R SMITH *Am J Pub Health* 25 (1935) 442 (A H B)

Diphtheria Toxoid—Value of Alum-Precipitated. A potent batch of alum preprecipitated toxoid was tested on five groups of children all of whom were Schick positive before inoculation. Each child received one dose (1 cc) of this material, and in 152 cases a final Schick test was performed one month after the injection. It has been shown that the figure 83.6 ± 2.0 represents the average percentage of children who became Schick negative within four weeks. The reactions were classified into three types—general local erythema and local induration. Generally these reactions were very mild but the occurrence of much more severe reactions in two cases shows that due care must be exercised in this work and emphasizes the necessity for a strict interpretation of the Moloney test.—E A UNDERWOOD *Lancet* 228 (1935), 137 (W H H)

Diphtheria Toxoids—Comparison of Value of Merthiolate and Phenol as Preservatives for Diphtheria toxoid is best preserved by merthiolate 1:10,000 at icebox temperature. After two years it showed better antigenic value than similar toxoid when preserved with 0.5 per cent phenol.—OLGA R POVITZKY and MINNIE EISNER *J Immunol*, 28 (1935) 209 (A H B)

Disinfectants—Advances in Testing of. The Food and Drug Administration method of testing antiseptics which was designed by Ruhle and Brewer has the advantage of saving time work and material, and of making possible uniform and comparable results in the hands of different workers. The culture medium is better suited for bacterial growth and the method is not limited to a single test organism as is the case with the Rideal Walker and the U S Hygienic Laboratory methods. A table comparing the results obtained with the three methods is given. The F D A process is particularly well adapted for testing coal tar antiseptics and iodine solutions of various kinds and concentrations.—E MAIER *Pharm Ztg* 80 (1935) 228 (G E C)

Germicidal Substances—Comparison of the Resistance of Bacteria and Embryonic Tissue to II Metaphen. Phenol and metaphen inhibit tissue growth to the limits of dilution of 1:840 and 1:76,000. The inhibition of staphylococcus growth occurs with phenol at 1:65, metaphen

1 6000 This gives for both approximately the same toxicity index of 12.9 and 12.7—A. J. SALLE and A. S. LAZARUS *Proc Soc Exptl Biol Med*, 32 (1935), 937 (A. E. M.)

Herpes Virus—Attempts to Produce Immunity with Large Quantities of Killed Dead virus is not able to produce any immunity—EARL B. MCKINLEY and RANDALL L. THOMPSON *Proc Soc Exptl Biol Med*, 32 (1935) 915 (A. E. M.)

Meningococcus Antitoxin—Ferry's Meningococcus antitoxin prepared by using, as antigens, soluble toxins of Types I, II, III, IV meningococci, appears to be a potent therapeutic agent for Types I and III meningococcus meningitis, as shown in a recent small series in London. Its potency in Type II meningitis is much more doubtful. It is suggested that intensive dosage—viz., twice daily spinal injections in early acute stage, combined with one or more intravenous injections—is an important factor in the success of treatment—N. S. BANKS *Lancet*, 228 (1935), 856 (W. H. H.)

Placenta Serum—Preparation of Anti-Measles Y. A. Finkelstein, et al (*Sov Paediat*, 3 (1934), 34) describe a method of preparing anti measles serum from placenta of normal women. The main features of this technique are heating the serum with chloroform to a temperature of 60° C., and testing its sterility subsequently by animal and cultural inoculations. The sera derived from thirty to forty placenta are then mixed before they are ready for use. The proportion of anaphylactic and other complications remained relatively low at 0.3 to 0.4 per cent. No difference in effect could be detected between convalescent and placental serum—*Brit Med J*, 1 (1935), 56 (W. H. H.)

Pneumococci—Application of the Neufeld Reaction to the Identification of Types of The Neufeld reaction for identification of pneumonia types with the consequent swelling of the capsules which become more distinct and show a ground glass appearance is still the most rapid, as well as a very accurate method of identifying the 32 types of pneumococci. Types I to XXXII are specifically reacted upon by homologous rabbit antisera. Specific type sera can be produced in rabbits. Type III and type VIII may react to the same type antisera—GEORGIA M. COOPER and ANNABEL W. WALTER *Am J Pub Health*, 25 (1935) 469 (A. H. B.)

Pneumococcus—Antigenic Characteristics in Man of Certain Products of the The duration of the immunity following the use of vaccine or of fractions is variable in different individuals but may persist at least over a period of three months. The antigenic response to type I vaccine is largely homologous while in type II vaccine the various fractions, though in different degree show much greater heterologous response—LLOYD D. FELTON, W. D. SUTLIFF and B. F. STEELE *J Infect Dis* 56 (1935) 101 (A. H. B.)

Staphylococcus—Special Variety of, Concerned in Food Poisoning The power of staphylococci to be the etiological factor in food poisoning cannot be recognized by agglutination, hemolytic or chemical characteristics. The staphylococcal food poisoners are therefore still undifferentiated strains—JOSEPH STRIATAR and EDWIN O. JORDAN *J Inf Dis* 56 (1935) 1 (A. H. B.)

Sterilization in Pharmaceutical Practice The value of two new sterilizing agents, namely, 'Katadyn' and 'Zephrol' is reported. Sterilization is discussed in detail and the following substances are arranged according to their ability to check the growth of organisms and their bactericidal action. The number designates the reciprocal value of the smallest fraction which gives an active dilution.

Substance	Titer	
	Checks Growth	Kills in 48 Hrs
Nipagin sodium	450	
Vuzin	500	200
Nipazol sodium	500	
Nipagin	800	
Nipazol	800	
Benzoic acid	1000	200
Nipabenzyl sodium	1000	400
Chloramine	1500	1500
Hexylresorcinol	1500	500
Quinosol	2000	400
Rivanol	2500	1500

Trypaflavin	3000	1750
Malachite green	3000	2000
Methylene Blue	5000	2000
Methyl violet	5000	2500
Brilliant green	6000	3000

H ESCHENBRENNER *Pharm Monatsh*, 16 (1935), 26-29 (H M B)

Streptococci—Studies on the Respiratory Mechanism of One of the initial products of metabolism in all streptococci is H_2O . A thermostable peroxidase was found to be present which appears to be intimately related to the thermolabile dehydrase mechanism in the cell. The ability of streptococci to activate 101 chemicals was studied which demonstrated the dehydrogenation of many carbohydrates. The dehydrase-peroxidase system plays an important role in the respiration of the streptococci.—M. FARRELL *J Bact*, 29 (1935), 411 (A H B)

Tetanus Toxin—Immunizing Activity of, in Lanolin Immunization of rabbits against tetanus was produced by the injection of a non-attenuated tetanus toxin in lanolin and olive oil. The rabbit was injected with 4 cc of a mixture of 2 cc of toxin, 3 cc lanolin and 6 cc olive oil (equivalent to 10 L. D. s for the rabbit or 20 000 L. D. s for the guinea pig). The injection material was slowly resorbed. There were no signs of tetanus. Twenty-two days later the serum of the rabbit contained $1/8-1/10$ antitoxic units/cc and 1 cc was capable of neutralizing 100 M. L. D. for the guinea pig. A second injection increased the antitoxic titre to 2 units/cc in 11 days.—G. RAMON and E. LEMETAYER *Compt rend*, 200 (1935) 592, through *Squibb Abstract Bull* 8 (1935) A 453

Tetanus Toxin—Photodynamic Effect of Methylene Blue on Tetanus toxin can be activated by optimum concentrations of methylene blue in the presence of light. *In vivo*, however methylene blue does not inhibit the effect of tetanus toxin.—KARL M. LIPPERT *J Immunol* 28 (1935) 193 (A H B)

Tuberculous Antibodies—Latent Tuberculo-protein (TPT) is prepared by precipitation with trichloroacetic acid and is 1.6 times as strong as Kock's Old Tuberculin for cutaneous tests. Specific tuberculous antibodies appear to be exfoliated into the circulation of patients who at some previous time had had a tuberculous infection as indicated by the positive skin test. If antibodies indicate in any way, resistance against tuberculosis, the results would suggest a persistent protection against tuberculosis long after the original infection.—A. B. BAKER and M. WETHERBY *J Infect Dis* 56 (1935) 165 (A H B)

Zephrol—Use of, in the Preparation of Sterile Solutions for Injection The article is a supplement to a topic published in *Pharm Acta Helv*, Nos 10 and 11 1934. This paper deals with a new disinfecting medium which has just come on the market under the name of 'Zephrol', a preparation of the I. G. Farbenindustrie, and which is labeled as a mixture of high molecular alkyl dimethylbenzyl ammonium chloride. The agent is an aqueous solution of 'Zephrol' which is clear yellowish white foams strongly on shaking, exhibits a faint pleasant odor and reacts weakly alkaline to litmus. Its activity in various strengths toward certain organisms and also their spores is stated. Tests are given which indicate its practicability for sterilizing the hands and rubber goods. It is non-irritant to mucous membranes in 0.5 or 1 per cent solution and is now being used in gynecological practice. The preparation is relatively non-toxic by mouth. In connection with the use of E. K. filters we believe to have found in 'Zephrol' a material suitable for the pre-sterilization of the apparatus. From the above properties, it appears that 'Zephrol' can be recommended for general use in the hospital as well as in the sterilization of filters. We have also developed an apparatus for more rapid filtering of media.—H. ESCHENBRENNER *Pharm Acta Helv* 10 (1935) 72 (M. F. W. D.)

CHEMISTRY

GENERAL AND PHYSICAL

Fusion Curves of Binary Systems Bromural and Veronal with Salol and Phenacetin. Two component mixtures, as follows, were investigated: (I) bromural-salol, (II) bromural-phenacetin, (III) veronal-salol, (IV) veronal-phenacetin. The aforementioned systems all form eutectic mixtures and in the liquid state the components are miscible in all proportions. The weight per cent compositions for corresponding crystallization temperatures were as follows:

(I) 3.5 per cent bromural at 40.8°, (II) 5.3 per cent bromural at 109.0°, (III) 1.5 per cent veronal at 41.2°, (IV) 26.2 per cent veronal at 121.6°—K. HRYNAKOWSKI and M. SZMYTÓWNA *Arch Pharm*, 273 (1935), 163 (L. L. M.)

ORGANIC

Alkaloids

Cinchona Alkaloids Ketone Formation with Sodium Amide The patent method of Chichibabin for preparing α -aminopyridine from the action of sodium amide on pyridine was used in an attempt to prepare amino derivatives of hydroquinine, quinine and cinchonine. However the alkaloid was transformed into the corresponding ketone instead—ALICE G. RENFREW and LEONARD H. CRETCHER *J. Am. Chem. Soc.*, 57 (1935), 738 (E. B. S.)

Ephedrine Alkaloid—Crystalline Forms of Report is made of an investigation undertaken to show that the hemi hydrate is the usual hydrate of ephedrine, to determine the melting point of anhydrous ephedrine and to ascertain the effects of different amounts of water on the melting point. The alkaloid was distilled at 25 mm., any water came over quickly, the receiver was changed and distillation continued. The anhydrous base boiled from 151–153°. The solidifying point was between 38.0° and 38.1°. To get a number of values, molten anhydrous alkaloid was put into a round bottom flask fitted with a stopper for an Anschutz thermometer and a stirring rod. Cooling to 30° and stirring brought it to constant value where it remained for some time. A known weight of water was added to the melted mass and the solidification temperature again determined. The addition of water lowered the melting point until with 1.5 per cent a eutectic mixture, ephedrine ephedrine hydrate melted at 32.1°. Further addition of water raises the melting point until with 5 per cent a maximum of 40° occurs. Boiling points were determined at various pressures. When crystallized from an anhydrous medium like ether, crystals obtained analyzed 100 per cent. Crystallized from water or dilute alcohol, they analyzed 95 per cent. Anhydrous crystals are very hygroscopic, while hydrated are stable. The anhydrous and hydrated bases differ also in crystalline form and in their solubility in oil—E. E. MOORE and D. L. TABERN *J. Am. Pharm. Assoc.*, 24 (1935), 211 (Z. M. C.)

Ergometrine Newly Discovered Alkaloid in Ergot There appears in the *Brit. Med. J.*, 1 (1935), 520, through *Pharm. J.*, 134 (1935), 321, a communication by Chassar Moir and H. W. Dudley relative to the constituent which according to their investigations is responsible for the clinical effect of ergot preparations. Particulars as to the separation of this constituent will be published later. This body, which has alkaloidal properties is soluble in alkalis and the commonly employed extractive solvents. The ergot investigated by the authors contained 0.1% alkaloids calculated as ergotoxine. The new alkaloid which has been named ergometrine comprises about $1/12$ of the total alkaloids. The effect of ergotoxine occurs much later than the effect of ergometrine. When 0.5–1 mg. of the new alkaloid is taken *per os* uterus contractions occur in 6.5–8 minutes, while with 2–3 mg. of ergotoxine the contractions first occur after 35 minutes. Intramuscular injection of 0.25 to 0.5 mg. and intravenous injection of 0.05 to 0.1 mg. give the same effect as the above dose, *per os*. The new alkaloid gives the same color reactions as the other alkaloids of ergot—*Pharm. Weekblad*, 72 (1935), 345 (E. H. W.)

Ergot—Active Constituents of Pharmacological and Chemical Study After obtaining the total alkaloids in as pure condition as possible, those alkaloids having slow ergotoxine or ergotamine type of activity were separated from the promptly acting new alkaloidal principle or principles. Details of procedure are reported. The new substance has not been obtained in pure crystalline form so only approximate quantitative data are given. A tabulation of eight alkaloids with name of discoverer and date, supposed composition, oxytocic activity, color reaction, cockscomb and isolated rabbit uterine reaction is given. Properties of the new alkaloid and of the others are discussed. Pharmacological action of the new alkaloid was tested by several methods. Moir's clinical observation that there is an important difference between ergotoxine or ergotamine and crude aqueous or hydroalcoholic extracts of ergot is confirmed and also his conclusion that there is a highly important "unidentified" substance present but other of his apparent beliefs are disproved. The described procedure for chemical separation shows that all of the significant oxytocic property is in the "total alkaloidal fraction". A method is described for fractionating total alkaloids and also for purification of the new substance. The main difference in pharmacological action of the new alkaloid from formerly known ones is its prompt oxytocic action.

especially orally It probably is more soluble and more rapidly absorbable Differences are not so great when given intravenously or when compared on isolated smooth muscle Total alkaloids are absorbed only after passing into intestine of the cat and this is probably true in humans Aqueous or hydro alcoholic extracts injected intravenously or subcutaneously are intensely irritant due to the inert fraction Hydro alcoholic liquid extracts contain all the total alkaloids' and completely represent the drug in oxytocic activity but are suitable only for oral administration because of the presence of irritant inert constituents that are responsible for pain and abscesses when injected Aqueous liquid extracts do not contain all of the total alkaloids' but practically all of the promptly acting 'X alkaloid' The latter is the more important but the slow acting alkaloids add to duration of effect Solid or pillular extracts that are highly active can be prepared but most of those available have had alkaloidal activity destroyed by heat They owe most of the activity they have to 'X alkaloid' Method of assay should be chosen for reliability and precision and the author favors a modification of the Broom Clark Rabbit Uterus method though the colorimetric method offers possibilities The various methods will be considered in a separate report All the methods require a standard of comparison' but this standard has failed The author has recommended that ergotamine ethanesulphonate or ergotamine tartrate be made the bioassay standard The following conclusions are made by the author (1) The pregnant cat has been found to be a suitable test subject upon which to study comparatively the oxytocic activity of various types of preparations and constituents of ergot (2) A procedure involving oral administration of the ergot preparations has been described and used extensively for the above purpose Such a procedure can be successfully employed in investigating the chemical source of the significant oxytocic activity of ergot (3) Carefully prepared hydro alcoholic extracts of ergot such as Fluidextract of Ergot, U S P (U S P X or Interim Revision), or Liquid Extract of Ergot 1932 B P contain all of the important active principles of the drug Such preparations are rich in alkaloids and remarkably prompt and effective upon the uterus following oral administration (4) Aqueous extracts of ergot do not contain all of the important active principles of the drug They are deficient in ergot alkaloids but are never alkaloid free unless they are many years old or the alkaloids have been destroyed by excessive heat in their manufacture When carefully prepared these extracts are remarkably prompt and effective upon the uterus following oral administration This prompt and effective activity is entirely out of proportion to the ergotamine or ergotamine equivalents of such preparations (5) Ergotamine and ergotamine are indistinguishable in producing a much delayed and erratic action following oral administration The activity of these alkaloids is, therefore far from being completely representative of the drug itself or its crude extracts as formerly supposed (6) A hitherto unknown highly important active principle exists in ergot (7) Every trace of the significant oxytocic activity has been found to reside in the chemically purified total alkaloids' of the drug even in the so called aqueous extracts as shown by the prompt activity obtained from the 'Total Alkaloidal Fraction' in contrast to the complete lack of significant activity in the 'Alkaloid Free Fraction' (8) Ergotamine and ergotamine are not representative of the total alkaloidal activity' The new active principle appears, therefore, to be another member of the specific alkaloids of ergot since it followed the other alkaloids in the chemical procedure used in obtaining the Total Alkaloidal Fraction (9) The activity of aqueous extracts observed by Moir must have been due contrary to his belief to residual alkaloid' consisting mainly of the new alkaloid described in this report The alkaloidal deficiency of such extracts is due to the inefficiency of water in extracting the ergotamine or ergotamine Most of the more stable new alkaloid is readily extracted by water and hence appears in fairly representative amounts in such extracts (10) The new alkaloid has been isolated in a sufficiently pure amorphous condition to permit of certain pharmacological and chemical comparisons with the hitherto known alkaloids (11) The new alkaloid is closely related to ergotamine and ergotamine as is shown by similar chemical behavior and also as is shown by its similar pharmacological action when tested upon the isolated guinea pig uterus the isolated rabbit uterus the cockscomb and the carotid blood pressure of cats or dogs Its activity persists for hours as does that of ergotamine and ergotamine (12) The new alkaloid differs from ergotamine and ergotamine mainly by its much more soluble nature and by its more prompt and powerful oxytocic action following oral administration The greater solubility together with the probability that the new alkaloid has a smaller molecule compared with ergotamine or ergotamine undoubtedly accounts for the more prompt absorption and greater

effectiveness of the new alkaloid (13) All of the remarkable observations of Mour can be explained by the demonstration of the existence of the new alkaloid (14) None of the active oxytocic principles of ergot (the specific alkaloids) is absorbed to any significant extent from the stomach of the cat, following oral administration (15) All of the active oxytocic principles of ergot (the specific alkaloids) are absorbed with varying degrees of rapidity from the intestine of the cat following oral administration The new alkaloid is promptly absorbed while ergotamine and ergotamine are absorbed with great difficulty This difference in absorption rate also manifests itself following subcutaneous or intramuscular injection (16) Ordinary aqueous or hydro alcoholic extracts of ergot are intensely irritant to the tissues following subcutaneous or intramuscular administration Severe abscesses develop at the site of injection, especially following the larger doses (17) The irritant and abscess forming properties are not due to the important active principles (the specific alkaloids) of ergot They are due to the otherwise pharmacologically inert extractives appearing in the liquid extracts (18) The color of an ergot preparation is no indication of its value or activity The purified total active principles are colorless in solution (19) Either ergotamine ethanesulphonate or ergotamine tartrate constitutes the best available "standard" for comparison in the evaluation of ergot preparations by the currently accepted quantitative methods (20) The Isolated Guinea-Pig method, as usually applied (as in testing Liquor Pituitarii, U S P), is wholly unreliable as a means of insuring significant activity in ordinary aqueous or hydro alcoholic extracts It measures chiefly the worthless non specific amine activity of such extracts (21) Clinical activity in reasonably standardized amounts can be insured by requiring official liquid ergot extracts to contain a total specific alkaloidal activity, equivalent to approximately 0.05 per cent, in terms of either ergotamine ethanesulphonate or ergotamine tartrate, when tested by the Cockcomb method, the Epinephrine Inhibition Rabbit Uterus method or the Colorimetric method This will provide for the presence of essentially all of the more important new alkaloid present in the parent drug plus varying but larger proportions of the less important ergotamine or ergotamine None of these methods can serve to differentiate between the new alkaloid, ergotamine or ergotamine in crude extracts (22) Solid or pilular extracts can be made to contain a satisfactory amount of activity by extracting properly and avoiding the use of excessive heat and exposure to oxygen in the process of concentration (23) The non specific amino bases of ergot (histamine tyramine choline, etc.) contribute nothing of a desirable nature to the characteristic oxytocic activity of the drug—MARVIN R. THOMPSON *J. Am. Pharm. Assoc.*, 24 (1935), 185 (Z. M. C.)

Ergotocin The authors found that the alkaloids ergotamine, ergotamine and sensibamine are uniformly ineffective when administered to human mothers in doses of 2 mg. They found, however, that some fluid extracts of ergot were effective in doses corresponding to 3–4 Gm. of ergot. After a year and a half the authors were finally able to isolate a principle which they have named ergotocin which is uniformly effective in human mothers when administered orally in doses of 0.3 mg. and intravenously in doses as low as 0.1 mg. Three-tenths mg. of ergotocin roughly corresponds to 3–4 Gm. of crude defatted ergot. Ergotocin salts as well as the free base are white crystalline substances. The base melts at 155°. The picrate which is red melts at 195–197°. It differs from the other ergot alkaloids (ergotamine, ergotamine and sensibamine) in that it is not precipitated by Mayer's reagent in dilutions greater than 1:7500, while the other alkaloids are precipitated in dilutions of 1:200,000 to 1:2,000,000. The chemistry of ergotocin will be reported later. Ergotocin is not present in all samples of ergot acceptable on the basis of the U S P assay and therefore the authors believe that the isolation of this principle will put ergot therapy on a rational basis. The principle has low toxicity and small dosage gives prompt action in uterine hemorrhage—M. S. KHARASCH and R. R. LEGAULT *Science*, 81 (1935), 388 (E. H. W.)

Harmine and Harmaline II Nitro and Amino Derivatives of *O*-Alkyl Ethers of Harmol and Harmalol Harmine is demethylated readily by heating in an open vessel with concentrated sulphuric acid at 120°, with the formation of quantities of harmine sulphate. Sulphonation is avoided by the use of phosphoric acid (d. 1.7) at the same temperature thus affording harmol in a yield of about 78 per cent of the theoretical. Demethylation of harmaline with sulphuric acid produces a mixture of harmol and harmalol, but phosphoric acid at 150° gives harmalol in about 80 per cent yields. The phenol bases were alkylated by means of *p*-toluenesulphonic acid esters: the ethyl ether m. p. 199–200°, *n*-propyl ether, m. p. 203–204°, *n*-butyl ether m. p.

stalks and inflorescences of *C. martinii* var. *motia* grown at Palermo from seed obtained from Bombay were distilled separately and gave the following yields of insoluble and of soluble oils, respectively: leaves 0.04, 0.07%, stalks 0.0, 0.03%, blossoms 0.347, 0.128%. The insoluble leaf oil, soluble leaf oil and soluble stalk oil had the following analytical characteristics: d_{15}^{20} 0.9201, 0.9134, 0.901, α_D^{42} 17.1°, 29°, n_D^{20} 1.4175, 1.3685, 1.3683, acid no. 0.001, 0.009, 0.009, ester no. 16.80, 7.47, 18.67, ester no. after acetylation 119.17, 104.53, 179.20, total alcohols 36.55, 31.59, 57.67%, combined alcohols 4.68, 2.08, 5.20%, free alcohols (as geraniol) 31.87, 29.51, 52.09%, soluble in 11, 4, 10 volumes of 70% alcohol, and in 2, 2, 2 volumes of 80% alcohol—F. BRUNO *Boll. stud. inform. R. Giardino Col. Palermo*, 23 (1934), through *Parfums de France*, 13 (1934), 33–42 (in French and English) (A. P. C.)

Essential Oil Industry in Seychelles An account of the present position of the industry and the possibility of improvement—W. H. HAINES *Bull. Imp. Inst.*, 32 (1934), 545–559 (A. P. C.)

Essential Oils—Exports of, from Sicily 1934 A table containing a list of exports of essential oils during 1934 from Sicily, per steamer and rail, in lbs. Avoirdupois net is given. The table contains the chief importers of lemon, sweet orange, bitter orange, bergamot, mandarin and sundry oils. Compared with the figures for 1933, the exports last year declined by 12,000 lbs. but they were over 400,000 lbs. above the shipments in 1932. Great Britain occupies the first place among the importers of Sicilian essential oils. The United States is second—*Perf. and Ess. Oil Rec.*, 26 (1935), 75 (A. C. DeD.)

Essential Oils from Seychelles Two specimens of oil of *Cymbopogon nardus* (L.) Rendle (citronella oil) had analytical characteristics similar to those of Ceylon oil of citronella. A sample of oil of *C. citratus* (DC.) Stapf (lemongrass oil) was similar to commercial Cochinchina lemongrass oil, but had a citral content (86.5% total aldehydes by volume, by the bisulphite method) above the average for the commercial Cochinchina oil. A sample of oil of *C. flexuosus* (Nees) W. Watson? (or possibly a hybrid between *C. flexuosus* and *C. nardus*) and a sample of oil of *C. confertiflorus* (Steud.) Stapf possessed the characteristics of low grade citronella oils, a sample of oil of *C. flexuosus* (Nees) W. Watson had the characters of a low grade lemongrass oil. Oil of palmarosa distilled experimentally in the Seychelles, had normal characteristics and was of good quality, the total alcohols and ester contents were slightly higher and the free alcohols lower than usual in the commercial Indian oil. Of two samples of gingergrass oil examined, one was of normal characteristics and the other had characteristics suggesting it had been derived from a mixture of gingergrass and of palmarosa grass. Samples of oil distilled from fresh leaves, from dried leaves, from hairy or pilose leaves, and from smooth or glabrous leaves of *Eucalyptus citriodora* had normal characteristics and contained high citronellal contents (78.7 to 82.6%). Oil distilled from the plant known locally as "Toc Maria" and identified as *Ocimum basilicum* Linn. (?) had constants resembling those of commercial Réunion sweet basil oil rather than those of the French, German, Algerian and Spanish oils. Oil of *O. viride* Willd. had constants falling within the range of previously examined oils from the same source, and the phenols (48%) consisted almost entirely of thymol, the oil would therefore be suitable for the production of thymol. Oil of *O. americanum* Mill. (= *O. canum* Sims) had the following characteristics: d_{15}^{20} 0.9181, α_D^{20} -3.63°, n_D^{20} 1.4878, acid value 12.4, aldehydes and/or ketones (via bisulphite) 71% by volume, aldehydes as citral (via hydroxylamine) 62.3% by weight, acids and phenols (by absorption with KOH) 8%, soluble with slight opalescence in 2.2 volumes of 70% alcohol at 15.5°. The aldehydes consist mostly of citral, suggesting the existence of a third botanical species of this plant (cf. Glichitch and Naves *Chimie & Industrie* Special No., 1029–1033 (June 1933)). Oil of *O. sanctum* Linn. had d_{15}^{20} 0.9840, α_D^{20} -29.37°, n_D^{20} 1.5210, phenols (by absorption) 33%. The phenols consisted almost entirely of eugenol, contrary to the oils examined by Brooks, in which estragol (methylchavicol) was the chief constituent. Oil obtained in 0.665% yield from an unidentified species of *Ocimum* had the following analytical characteristics: d_{15}^{20} 0.9385, α_D^{20} -9.93°, n_D^{20} 1.4871, acid value 6.5, ester value 1.2, ester value after acetylation 175.7, equivalent to 'total acetylizable constituents' (as $C_{10}H_{16}O$) 55.6%, apparent cineole (via α -cresol) 17.7%, soluble in 1.8 volumes of 70% alcohol at 15.5°. The odor resembled that of spike lavender oil, but the oil had a considerably higher alcohol content than that of spike lavender. A sample of cinnamon root bark oil obtained in 1% yield contained only 36% cinnamic aldehyde and was much below B. P. standard in all respects. A sample of patchouli oil, distilled from plants which had been introduced into

Seychelles from Ceylon as representing the typical Singapore variety, had characteristics differing considerably from those of Singapore patchouli oil (derived from *Pogostemon patchouli* Pallett) but generally similar to those of Java oil (said to be distilled from *P. heyneanus* Benth, a species indigenous to India)—*Bull Imp Inst*, 32 (1934), 511-539 (A P C)

Essential Oils from Seychelles A Survey of the Industry and Suggested Improvements A short discussion of each of the following oils citronella, lemongrass, palmarosa, *Eucalyptus citriodora*, ocumum, cinnamon root-bark, patchouli oils is given—*Perf and Ess Oil Rec*, 26 (1935) 78 (A C DeD)

Geranium Oil—Characteristics of 1934 Algerian The limits of the analytical constants of 160 samples of the 1934 Algerian harvest of geranium oil were in substantial agreement with those reported for the 1932 and 1933 harvest—*B ANGLA Ann Fals*, 28 (1935), 97-99 (A P C)

Mushrooms—Essential Oil from Investigations were made with fungi collected in the virgin forests of Brazil The chemical constitution of well developed individuals of the genera *Clitocybe*, *Cortinarius*, *Hydnum*, *Hygrophorus*, *Hypholoma*, *Lactarius*, *Pleurotus*, *Polyporus* and *Psalliota* is listed Investigation has shown that the greater part of the essential oil in fungi exists in glucosidal combination in the stems and cap, while another portion, rather small in quantity, is combined in the wax-like cover of the outside surface of the cap For small scale laboratory purposes the glucosides of the species of fungi referred to were obtained by careful evaporation of the aqueous extracts under reduced pressure, the process resulting in viscid residues in most cases of extremely bitter taste, and ready solubility in alcohol Hydrolysis was attempted with emulsin, invertase and diastase but without any effect whatever It became evident that only specific enzymes of the same type, if not the identical kind, were able to produce hydrolysis The enzymatic ferments may be extracted from the fungi by means of glycerin and precipitated from this solution by benzene Irrigation with water, extended over a period of some days, may conveniently precede the extraction with glycerin, although by this process a certain proportion of enzyme is lost, the resulting substance is apparently more active, whether it is of a greater purity cannot be established Typical results obtained from the treatment of fungi such as have been mentioned are given in a table—*FRED W FRIESE Perf and Ess Oil Rec*, 26 (1935), 91 (A C DeD)

Umbellulone—Some Pharmacological and Bactericidal Properties of Report is made of an investigation of the oil of the California laurel and its ketone Preliminary investigation included a study of the effect of umbellulone on blood *in vitro* and *in vivo*, its effect upon the intact heart of the frog and upon the atropinized frog heart, effect of physostigmine on umbellulonized frog heart and its effect on unanesthetized animals In testing the fungicidal action of the oil and the umbellulone the organisms used were *Monilia tropicalis* and *Trychophyton interdigitale* For germicidal action the organisms used were *E. typhi* and *Staphylococcus albus* and the wet filter-paper method and the Agar Plate Method of the Food and Drug Administration were tried Several experiments on segments of isolated intestine were carried out, using cats' and rabbits' intestines Effect of the ketone on the respiration and blood pressure was tried on dogs Summarizing results it was found that umbellulone in blood produced methemoglobin *in vitro* and *in vivo* and decided hemolysis of human, guinea pig and horse blood Injected intraperitoneally into a guinea pig it caused asphyxiation and death Inhalation by guinea pig, irritated mucous membrane of eyes and nose and caused irregular respiration but no failure In dilutions of 1:50 it killed *Monilia tropicalis* and *Trychophyton interdigitale* in 1-, 30- and 60 minute contacts In presence of blood, peptone and gelatin there was a slight loss in fungicidal power It killed *E. typhi* and *Staph. albus* in dilutions up to 1:500 in 15 minutes' contact Phenolic coefficient was estimated as 6.25 It decreased frequency of the frog heart, caused loss of tone, decreased ventricle contraction, stoppage in diastole Injection of atropine, caffeine or adrenaline had no effect It probably acts on same nerves and fibres as atropine Intravenous injection caused lowering of blood pressure and failure of respiration in dogs These results with post mortem examination indicate that umbellulone probably acts as a depressant, produces rapid methemoglobin apparently blocks pulmonary circulation, causes vaso dilation of heart and large vessels The minimal lethal dose in dogs is about 0.178 cc per Kg of body weight death being due to failure of respiration and in a few minutes stoppage of the heart—*MILLS 1 DRAKE and ERNST T STUHR J Am Pharm Assoc* 24 (1934), 196 (Z M C)

Fixed Oils, Fats and Waxes

Dihydroxypropyl Esters of Fatty Acids—Preparation of, and Use in Emulsions and Ointments Containing Water The various modern offerings of emulsifying agents are considered, especially the group consisting of an ester of a polyvalent alcohol, either ethylene glycol or glycerol with various fatty acids. A trade preparation "Tegin" (Goldschmidt, Essen) is taken as a prototype. Analysis shows this to be 4.38% sodium stearate, 10.11% stearic acid, 76.45% stearic esters of glycerol and 9.06% water and free glycerol (by difference). The stearic esters are a mixture of about equal parts of mono- and distearins. The content of sodium stearate determines that the emulsion will be of the type oil-in-water. A series of such esters has been prepared in the Control Laboratory of the Danish Apothecaries Society. Thus, hydroxyethylstearate may be made either from ethylenedichlorhydrin and potassium stearate or from ethylene glycol and stearic acid. Synthesis by the latter method is described in detail. In the same way an hydroxyethyl oleate can be made. The glycerol ester, *dihydroxypropyl stearate* or "monostearin" can be made in pure form by several methods described in the literature but for the purpose desired the inexpensive method of direct reaction of the alcohol and fatty acid gives a satisfactory mixture of mono-, di- and tri-stearates, chiefly, however the monostearates under the conditions described. *Preparation*—500 Gm stearic acid and 400 Gm glycerol (both of high purity) were mixed in a large flask and gradually brought, with boiling off of the water content of the glycerol, to 250° and held there one half hour. The whole operation takes about 2 hours. After cooling to 100°, the mixture was poured into a dish, then cooled to a cake, separated from excess glycerol, washed and dried. The melting point was the same as that of "Tegin," 57° C. It did not, however, contain the sodium stearate of the "Tegin" formula. If made from cheaper commercial stearins, the odor was unpleasant. The preparation was soluble, one part in less than 10 parts of chloroform, in 40-50 parts ether, in about 100 parts benzol, in about 1000 parts petrol ether and in over 1000 parts alcohol. It was practically insoluble in water. In the same way a mono olein preparation was made from pure oleic acid and a mono laurin from *Acidum Cocos*, Ph. Dan. (the fatty acids of coconut oil). Preparations from fatty acids of castor oil or of linseed oil are also suggested. An example of the use of the monostearin in a cosmetic ointment is cited. To form some sodium stearate to each 100 Gm of the melted monostearin, 15 cc of *N/1* sodium hydroxide are added before the remainder of the cosmetic formula is mixed in. The colloid chemical theory of the influence of the emulsifying agent on the charge of oil droplets is discussed. The monostearin is not useful if acids or heavy metal salts are to be added to the ointment. In these cases amine salts of fatty acids are better emulsifying agents, for example, the diethylethylenediamine salt of oleic acid $C_{18}H_{33}CONHCH_2CH_2N(C_2H_5)_2$ ("Sapamine," Ciba). The phosphate, lactate or acetate of this amine is sometimes used as an emulsifying agent. The water-in-oil creams, such as lanolin cetyl alcohol-vaseline ointments, etc. are also discussed. Here cholesterol or cetyl alcohol usually serves as the emulsifying agent. Mono olein or monolaurin can be used for this type of preparation. The use of mono glycerides in other types of emulsion preparations, such as liniments, is also discussed.—E. V. CHRISTENSEN *Arch. Pharm. og Chem.*, 42 (1935), 172, 197. (C. S. L.)

Hawthorn Fruit—Oil of No chemical studies of the fruit of the hawthorn have been reported in the literature. The characteristics of the fruit according to Grafe are given. The fruits were reduced to a coarse powder in a ball mill after drying as completely as possible at 98° in a drying chamber. Table I gives the results of an investigation of the kernels in terms of both the original and the dried fruits. The presence of about 48% crude fibre accounts for the difficulty experienced in powdering the material. The fruits are used chiefly (in Switzerland) in the preparation of hawthorn tea, while in other places they are used as a substitute for coffee. The tea made from the kernels is recommended for almost all possible sicknesses. A tea was prepared in the proportion of 60 Gm to 1 L. water filtered, studied and the results tabulated. Lastly, the oil extracted from the dried and powdered fruits with ether was completely investigated as to physical constants and some qualitative tests for the presence of various constituents such as phytosterol, etc. The oil was of an orange brown color, most of the color being due to unsaponifiable material.—J. PRITZGER and R. JUNGKUNZ *Pharm. Acta Helv.* 10 (1935), 75. (M. F. W. D.)

Palm Oils—Composition of Commercial IV. Progressive Hydrogenation as an Aid in the Study of Glyceride Structure. During hydrogenation the mixed palmito C_{16} glycerides frequently become completely hydrogenated in preference to the tri C_{18} -glycerides and to a less

marked extent, dipalmito oleins are often hydrogenated preferentially to monopalmito dioleins. By comparing the fatty acid components of the fully saturated and mixed saturated-unsaturated glycerides in a series of fats obtained by hydrogenation of a natural fat to various stages, it is possible to ascertain which of the classes of glycerides have passed into the completely hydrogenated state at different stages of hydrogenation and to select stages at which all dipalmito and some monopalmito glycerides (but no tri- C_{18} glycerides) have become fully hydrogenated. At these points the remaining mixed saturated-unsaturated glycerides then include only monopalmito di- C_{18} - and tri- C_{18} glycerides, and a further estimation of the tri- C_{18} glyceride content of the original fat becomes possible. The respective percentage compositions of a Cape Palmas oil and a Belgian Congo oil follow: myristic acid 1.6, 1.3, palmitic acid 32.3, 41.4, stearic acid 5.5, 4.7, oleic acid 52.4, 42.9, linoleic 8.2, 9.7.—A. BANKS, H. K. DEAN and T. P. HILDITCH. *J. Soc. Chem. Ind.* 54 (1935), 77T. (E. G. V.)

Rose Mallow Seed—Oil of Analysis of Rose Mallow seed gave 20.23% of an ether-soluble oil resembling cotton and okra seed oils and consisting of glycerides of oleic acid (33.12%), linoleic acid (45.53%), palmitic, stearic and arachidic acids (15.60%) and unsaponifiable material (1.34%).—CHARLES BARKENBUS and SARAH T. THORN. *J. Am. Chem. Soc.*, 57 (1935), 728. (E. B. S.)

Shark Liver Oil Liver oils from five species of shark have been examined. Estimation of vitamin A was made colorimetrically by the antimony trichloride method using a biologically assayed cod liver oil for comparison. Free fatty oil and unsaponifiable matter were determined. Commercial samples were very poor in taste and color and with one exception inferior to cod liver oil in vitamin A. Since unsatisfactory conditions might be due to rendering methods, fresh livers were carefully rendered and tested. Two were considerably more potent in vitamin A, they were only one-tenth as strong in vitamin D. They were all free from bad odor and taste. All deposited stearine at room temperature.—W. S. JONES and W. G. CHRISTIANSEN. *J. Am. Pharm. Assoc.*, 24 (1935), 295. (Z. M. C.)

Glycosides, Ferments and Carbohydrates

Proteolytic Enzyme—Content of, in Latex from the Fig Tree (Ficus Carica L.) There is a marked seasonal variation in the amount of enzyme present per unit volume of sap and the concentration is lowest in early summer.—BENJAMIN H. ROBBINS. *Proc. Soc. Exptl. Biol. Med.* 32 (1935), 892. (A. E. M.)

Proteolytic Enzyme in the Latex from the Fig Tree (Ficus Glabrata) p_H of Optimal Activity The optimum hydrogen ion concentration for the ficin gelatin proteolysis is p_H 5.—BENJAMIN H. ROBBINS. *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 894. (A. E. M.)

Strophanthus Hispidus—Constituents of The author states that the family Apocynaceae is especially rich in plants containing as their active constituent glucosides having the therapeutic properties of heart tonics. To this family belong the many varieties of strophanthus which contain a heart-stimulant glucoside located in the seeds as well as in the bark of the plant. Fraser, Feist, Hefter, Sachs and especially Jacobs and co-workers undertook many investigations on strophanthus seed. *Strophanthus kome hispidus* and *s. emini* all contain the constituent strophanthidin $C_{23}H_{42}O_6$. Besides strophanthidin it contains another glucoside periplogenin having the formula $C_{23}H_{44}O_6$. Arnould isolated ouabain $C_{29}H_{44}O_{12}$ from *Strophanthus gratus*. One of the products of the hydrolysis of ouabain, that is ouabagenin $C_{27}H_{44}O_8$, he was unable to isolate. The reason for this is that ouabain does not hydrolyze in acid solution like strophanthidin, but the "genin" is rather destroyed by hydrolysis. Jacobs and Bigelow isolated from ouabain with the use of a special method, a crystalline "genin," which contained one carbon atom less (C_{22}) than the original ouabagenin (C_{23}). This carbon atom separated out during the splitting up of the compound. In *Strophanthus sarmentosus*, Jacobs and Heidelberger have isolated sarmentocymarin, $C_{33}H_{46}O_6$, and then through hydrolysis they obtained sarmentogenin $C_{23}H_{40}O_6$. Because of close resemblance of all strophanthus seed, positive identification of their constituents is very difficult. A sample labeled *Strophanthus hispidus* was examined and through hydrolysis other "genins" were obtained in place of strophanthidin. The reason for this is not known. It was not possible to crystallize out the glucoside at first so that an acid was added to the crude mixture. Two "genins" were thus isolated, A $C_{23}H_{42}O_6$ and B $C_{23}H_{40}O_6$ which belonged to the same group of plant "genins" as strophanthidin, periplogenins, etc. Likewise they contained 23 carbon atoms

and gave a positive test with sodium nitroprussate and alkalis. The "genin" A, ($C_{21}H_{32}O_4$) has two hydroxyl groups which can be easily acetylated. In the molecule there is a double bond which can be hydrated by the removal of an (OH) group. The original "genin" would have had the formula $C_{23}H_{34}O_4$ which is an isomer if not identical with sarmentogenin which also has two hydroxyl groups. The "genin" B has the formula $C_{23}H_{36}O_4$ and is also unsaturated, three molecules of water were taken up during hydration. The original "genin" has the formula $C_{21}H_{32}O_4$ which is isomeric with ouabagenin. The relation to sarmentogenin and ouabagenin is not well established but can be indicated as monoanhydro hispidogenin A, and dianhydrohispidogenin B—R TSCHESCHE *Ber*, 68 (1935), 423 (G B)

Tea—Classification of Leaves and Stems of The tea found on the market is composed of buds, leaves, stems and young branches (twigs) of the tea shrub, *Thea chinensis*. On analysis all these constituents have the same composition, outside of the stems and young branches (twigs) which contain from 1.8–2.6% less "them" and produces a tea infusion of lesser aromatic flavor—I CUCULESCU *Bul Fac Stiinte Cernauti*, 7, 28–30 *Cernauti Instit der univ*, through *Chem Zentr*, 106 (1935), 973 (G B)

Thevetin Cardiac Glucoside of Be-Still Nut The article consists of a description of the cardiac glucoside recently discovered by K. K. Chen. The substance was obtained from the Be still nut or *Thevetia neruifolia*, indigenous to South America but now cultivated in the East Indies, India, the Hawaiian Islands and Western Africa—*Chem and Drug*, 122 (1935), 456 (T G W)

Other Plant Principles

Drosera Rotundifolia—Constituents of A hydroxymethylnaphthaquinone, ($C_{17}H_{12}O_3$) m p 69–70°, and a second substance, m p 225°, were isolated from a steam distillate of the drug. From an ether extract of the dried residue remaining after steam distillation, there was obtained a brown crystalline quinone like substance in a yield of 0.001%. The compound $C_{11}H_8O_3$ was shown to be present also in *Drosera binata*—H DIETERLE *Arch Pharm*, 273 (1935), 235 (L L M)

Lupulin—Value of Fresh The active constituents of lupulin, which consist of an ethereal oil extract were examined using the barium-method of Fromme. These constituents were acid in nature. This examination proved further, that the highest percentages of ethereal soluble extract were obtained from the fresh drug, these constituents were named "crude lupulin". These constituents of ethereal oil are little prone to decomposition when obtained from fresh drug. The determination of the ether-insoluble extract, gives no clue as to the freshness of the drug. In contrast to this a high content of "crude lupulin" indicates that the drug is fresh. Should this (content) be of a soft consistency this would indicate presence of resins and oleoresin—A TOMINGAS *Pharmacia* 14 (1934) 223–237, *Tarta Univ*, through *Chem Zentr*, 106 (1935), 930 (G B)

Marshmallow Root—Acidity of, and Presence of Calcium Soluble in Acetic Acid Samples of freshly collected root and extracts prepared before and after drying at 100° were acid to litmus paper. Commercial samples also gave acid reactions with litmus paper. The fresh root was washed, peeled and decorticated. A mucilage was prepared in the cold using water acidified with acetic acid. The mucilage was filtered, the filtrate treated with ammonium oxalate, the precipitate was filtered, washed and calcined. The residue was taken up in diluted hydrochloric acid, the solution neutralized with ammonium hydroxide and treated with ammonium oxalate in acetic acid medium. Calcium oxalate crystals formed. Samples of decorticated root yielded the following ashes: 3.95, 4.35, 4.05, 3.9 and 3.95%—P DUMONT and A DE CLERCK *J pharm Belg* 17 (1935), 305–307 (S W G)

Monarda Fistulosa—Sterols from Phytochemical Notes No 111 Unsaponifiable material from the saponified fatty oil from the leaves of wild bergamot was imperfectly crystalline. Upon purification and recrystallization good crystals were obtained. The sterol was acetylated and crystallized and the absence of stigmasterol was indicated. Testing of larger amounts may show presence of stigmasterol with a sitosterol—OLE GISVOLD *J Am Pharm Assoc* 24 (1935) 214 (Z M C)

Nânâcatl *Delium Fungus (Amanita Mexicana)* The active constituents of the fungus occur chiefly in the skin of the cap and are separated or the poisonous principles are destroyed by scalding with hot water in order that all of the properties are not completely lost and also made

unobjectionable to enjoy as a food Experiments show that the fungus contains at least 4 toxic principles and corresponding to these arise poisoning or intoxication cases with wholly different pathological pictures (1) the atropine like alkaloids affect the psychic exaltation with the feeling of pretended strength and a desire to show this property All secretions are strongly increased, pulse weak and easily repressed, (2) symptoms due to muscarine, and (3) the substances causing the real intoxication with its characteristic hypersensibility, with delirium of hours duration and finally stupor is unknown in our pharmacology as another of the fly-killing fungi An historical account, the toxicology and the nature of the intoxication are discussed fully —V A REKO *Pharm Monatsh*, 16 (1934), 29-31 (H M B)

Pinus Sabiniana—Sterol from *Phytochemical Notes* No 113 After saponification of the fatty oil from the seed of the Digger's pine, the nonsaponifiable material yielded a sterol After purification the sterol crystals melted at 137.5° and the acetate at 127.5° The digitonide obtained from the mother liquid was decomposed with boiling xylene the resulting sterol and its acetate having the melting points stated above This sterol therefore appears to be a sitosterol —OLE GISVOLD *J Am Pharm Assoc*, 24 (1935), 290 (Z M C)

Toddalolactone *Chemical Investigation of Toddalia Aculeata* (Pers) Part 2 A Zeisel determination indicated two methoxyl groups in the molecule of toddalolactone ($C_{16}H_{20}O_6$) Carboxyl and phenolic groups are absent Two hydroxyl groups are present, one secondary, the other tertiary in character With phthalic anhydride, the lactone gave a crystalline monophthalate (m p, 180-181°) The hydroxyl groups occur on adjacent carbon atoms since the lactone, by loss of a molecule of water, gave a crystalline ketone, $C_{16}H_{18}O_5$, which was characterized by its phenylhydrazone and semicarbazone The presence of a lactone ring is shown by the fact that treatment with diluted sodium hydroxide in the hot afforded an acid $C_{16}H_{17}O_7$, melting at 178-179° $[\alpha]_D^{30}$ in methanol = +36.1° The structural features of toddalolactone are depicted as here shown

The positions occupied by the groups in the benzene ring are still undetermined —B B DEY and P P PILLAY *Arch Pharm*, 273 (1935), 223 (L L M)

Unclassified

Anesthetics—Some Colored Local Ten colored compounds were made by diazotizing procaine and coupling with various dye intermediates Those in which the diazotized procaine was coupled with methyl anthranilate *p* bromoaniline α naphthylamine, α -naphthylamine + α -naphthylamine methyl anthranilate + α naphthylamine and diazotized *p* nitroaniline + procaine showed anesthetic properties The compounds formed by coupling with hydrochloric acid salicylic acid resorcinol and methyl salicylate did not show anesthetic properties —J H GARDNER and L JOSEPH *J Am Chem Soc*, 57 (1935), 901 (E B S)

Benzofuroquinolines This article describes the preparation of certain derivatives of dibenzofuran with the hope of obtaining compounds which will exert in some degree morphine-like effects By application of Skraup's method to 3 aminodibenzofuran two isomeric "quinolines" were obtained These were hydrogenated to the py-tetrahydro derivatives and the secondary

bases thus obtained were converted into the *N*-methyl derivatives I and II. Physiological activity increased from the quinolines through the tetrahydro compounds reaching a maximum for the methyl derivatives. II was slightly more active than I—E. MOSSETTIG and R. A. ROBINSON *J Am Chem Soc*, 57 (1935), 902 (E B S)

Charcoal—Adsorption, Prepared from Crude Cellulose The majority of commercial charcoal showed from 2–93 times less adsorption activity than *Carbo Medicinalis* or *Carbo Adsorbens* from the modern pharmacopœias. Through simple carbonization of cotton (raw absorbent cotton), peat moss and other similar products, are often obtained more active products than the commercial charcoals. Factors to be taken into consideration in the power of adsorption of charcoals are: rapid carbonization of the loose structure (material), raw material gives better results than a slow charring of a compact, solid structure which permits little air to go through. The best charcoal was obtained through simple ignition of cotton in a crucible, its adsorption power for methylene blue was only 7 times less than *Carbo Medicinalis*. Renewed ignition in smaller crucibles increased from 2–12 times its former activity—Sr. BADZYNOKI *Wiadomosci farmac*, 61 (1934), 385–388, through *Chem Zentr* 106 (1935), 927 (G B)

Citric Acid The manufacture of citric acid is carried on in two steps, namely, the production of calcium nitrate and the conversion of the calcium citrate into citric acid. The calcium citrate is either prepared from lemons or by the fermentation of sugar. Each case involves the oxidation of sugars to citric acid. By the use of the fermentation method, pure cane sugar is used. It is minutely regulated as to its precise nutritive value and oxidized by a pure strain of a cultivated mold—*Chem and Drug*, 122 (1935) 435 (T G W)

β -Cyclopentyl and β -Cyclohexyl Glucosides—Biochemical Synthesis of The synthesis of β cyclopentyl glucoside in cyclopentanone is formed from adipic acid, and the product is reduced to cyclopentanol. The cyclopentanol is dissolved in alcohol and water, and then saturated with glucose. After standing for 12 hours, 1.5 Gm. of emulsin (prepared by precipitating casein with acetic acid, adding $\frac{1}{4}$ of its volume of 95% alcohol clarifying with kieselguhr, and reprecipitating the emulsin with four times its volume of 95% alcohol) is added and the mixture is stirred continually, at room temperature. At the end of two days, polarimetric observations are made until the rotation does not change. One gram of emulsin is then added to insure complete reaction and the mixture is then permitted to stand again until the rotation is constant. The solution is filtered, and then distilled completely in a vacuum. The residue is dissolved in boiling ethyl acetate and the rotation is levorotatory. To further purify, the solution is evaporated to dryness and the residue is dissolved in water. The aqueous solution is exhausted with ether, and the last traces of glucose are destroyed by yeast. The solution is distilled in a vacuum, and the residue dissolved in ethyl acetate. The resulting solution of β cyclopentyl glucoside does not reduce Fehling's solution. A description of the physical and chemical properties of this compound is included. **Synthesis of β Cyclohexyl Glucoside**—This synthesis is effected by saponification of the tetraacetyl derivative of β acetobromoglucose. The cyclohexanol is mixed with water and acetone. Glucose is added and the mixture agitated during 12 hours. The mixture is then filtered and 1 Gm. of emulsin is added. The angle of rotation is observed as before, and a modified extraction of the above compound is given, as well as the physical constants—J. VINTILESCO and C. N. IONESCO *J pharm chim*, 21 (1935), 241 (M M Z)

Dyes—Medicinal An address before the New York Branch of AMERICAN PHARMACEUTICAL ASSOCIATION was restricted to six dyes. The speaker's introductory remarks dealt with the antagonism shown by certain physicians to retail pharmacists. The apparent explanation was a feeling that the pharmacist was "allowing his interests to become so diversified in the field of commercial retailing" that he did not act for the best interest of his physician clients and they felt his information on technical subjects was getting exceedingly thin. The speaker discussed the question of defining dyes, it being nearly impossible to find a definition that is universally applicable. A medicinal dye is one that has been found by practical experience to be of use in the treatment of disease—they are not found by theorizing. One of the first artificial dyes was triphenol prepared in 1771. Commercial development was very rapid between 1890 and 1911. By 1914 Germany was far to the front but since the war, dye manufactures in other countries have excelled. The war brought on great interest in medicinal dyes and antiseptics. In the world dye situation at present there are four important competing groups: Methylene Blue, one of the oldest and most interesting dyes, has had much publicity over its use as an antidote for poisoning.

by cyanide, illuminating gas, carbon monoxide. There are better antidotes for cyanide, nitrites and sodium thiosulphate as well as sodium tetrathionate apparently are better. It is not likely to be useful in carbon monoxide poisoning because it apparently forms methemoglobin. Its surgical uses are in wounds, injuries or diseases of sinuses, mouth, pharynx, gums. Other uses are less well developed. Crystal Violet, hydrochloride of hexamethyl pararosaniline, appears to be especially effective against gram positive bacteria—staphylococci, the diphtheria bacillus. Neutral Acriflavine is the most toxic of the dyes in common use. Its widest use is for acute, subacute and chronic urethral gonorrhea. Scarlet Red Sulphonate is a complex sodium salt related to betanaphthol. Like Scarlet Red Medicinal Biebrich it stimulates growth of epithelial tissues. Brilliant Green has much the same indications as Crystal Violet but is a less efficient bacteriostat and more stimulating to wounds. A rather new use for it is in so called "barber's itch." Medicinal Fuchsin is said to be a mixture of rosaniline and pararosaniline hydrochlorides. The medicinal dye is not that used for staining. Athlete's foot, trichophytosis and similar infections are treated with a preparation containing medicinal Fuchsin. A new use of Fuchsin is for burns. Once Carron Oil was largely used, more recently the tannic acid treatment has had considerable use because of the theory that a burn protein produces the toxicity. This theory may not be completely tenable. Some investigators felt that the abstraction of tissue fluid was the principal underlying cause of the serious effects. Logical outgrowth of this theory was the introduction of large amounts of fluid and this treatment is routine in good hospitals, but this theory is probably not based upon the principal factor. A third theory recently proposed is that intoxication following severe burns is the direct result of infection. Treatment has been designed to eliminate infection. Originally a vaporizing spray of 1 per cent solution of Gentian Violet was used, later Crystal Violet was used, now it is thought a mixture of Crystal Violet, Acriflavine and Brilliant Green or Fuchsin may be best. Dyes are contraindicated about the eye. Dyes in excess of 0.5 Gm. should not be injected in solutions into closed cavities. They should not be used in dirty, crushed wounds until the wounds have been surgically cleaned up. Patients who have been taking large amounts of dyes internally should not be subjected to direct sunlight where it is intense.—
DAVID A. BRICE *J. Am. Pharm. Assoc.*, 24 (1935), 241 (Z. M. C.)

Ethyl Ether, U. S. P.—Stability of. It was found that U. S. P. ether, as supplied at the present time in large metal containers in this country, does not deteriorate rapidly when the container is opened. Using the Nessler reagent for aldehyde determination and potassium iodide for peroxides, results indicated no deterioration products as long as 68 days after the first opening of the large drums of U. S. P. ether. In clinical investigation, the anesthetist was found unable to distinguish the effects of drum ether in small cans labeled "for anesthesia" by the reaction of surgical patients (702), when ignorant of the source of the ether used. The authors conclude that there is no difference between the anesthetic effects of drum or anesthetic ether.—H. GOLD and D. GOLD *Anesthesia and Analgesia* 14 (1935), 92, through *Squibb Abstract Bull.*, 8 (1935), A-505.

Gelatin—Use of, in Medicine. Gelatin possesses properties which are more adapt to intravenous usage than is acacia. Acacia appears to have a viscosity equal to that of the blood and an osmotic pressure equal to that of the colloids in the blood under normal conditions. However, it is simply a mechanical agent rather than one activating body tissues. Gelatin not only possesses the properties of a gum, but also those of a nutrient, hemostatic and stimulant to antibody formation. It is also an animal tissue, with elements of an incomplete protein. The fear that sterilization of gelatin (140° C.) produces an ineffective preparation has been shown to be partially in error, because even though the product is less effective than the unsterilized preparation (possessing a possibility of tetanus spores) an increase in dosage is all that is necessary to obtain the desired results. Gelatin is a valuable adjunct to infant feeding and in adult dietaries. It is of particular importance in preparing special foods for invalids and convalescents. Only absolutely sterile gelatin should be used for medical purposes. Solutions for topical application range from 5 to 12 per cent, for subcutaneous or intramuscular injection not over 6 per cent, for intravenous use not over 2 per cent. Gelatin solutions may be used with dextrose, calcium gluconate or sodium chloride, or all may be used in combination, in hemorrhage. Gelatin is a reliable antibody stimulant.—
W. F. DUTTON *Clin. Med. and Surg.*, 42 (1935), 165 (W. H. H.)

Glycerol—Mixed Esters of, with Aliphatic Acids and Phosphoric Acid. An ester derived from 1 molecule of glycerol and 2 molecules of an aliphatic acid is treated at about atmospheric

temperature with phosphorous oxychloride in the presence of an acid-binding agent, e. g., pyridine and the product is poured into ice water to produce an acid ester of glycerol with phosphoric acid and the aliphatic acid. Examples are given of the manufacture of products from diolein, di-stearolin, dicrotonin and dilaurin. The products and their salts are of therapeutic value.—F. HOFFMANN-LA ROCHE and Co. Ger. Pat. 608 074, Jan. 15 1935 (Cl. 12o 5 04). (S. W. G.)

Hexamethylenetetramine—Production of Medicinal, from Technical Product. The purification of technical hexamethylenetetramine is accomplished by using a solution of 95% alcohol mixed with charcoal and this is finally dissolved in water. For laboratory details see original article. The total yield was from 75–76% U. S. P. product and only 10–12% of the total yield was technical. The total loss during the process was only 12–15%. The quantity of alcohol recovered during the experiment was from 70–75%.—M. WOLPE. *Ssoujet Pharmaz.*, 5 Nr. 3 (1934) 33–34. *Wiss. prakt.-pharmaz. Inst. d. Leningrad Health Clinic*, through *Chem. Zentr.* 106 (1935), 926. (G. B.)

Lac—Constitution of. The composition of lac varies within certain limits depending among other things on the host plant, brood climatic conditions and the method of collection. Lac itself, however much purified, is never a chemical entity. Stick lac, that is the resinous incrustation as removed from the twigs, contains dead insect bodies, the lac dye and wax, as well as the true resin constituents. The lac resin consists of hydroxy acids of the aromatic and aliphatic series, two of these acids, alemtic and shellolic have been isolated and identified.—R. BHATTACHARYA. *J. Soc. Chem. Ind.*, 54 (1935), 82T. (E. G. V.)

Perfumes—Synthesis of. Preparation of Methylene Ester of Pyrocatechol. A study of the preparation of the methylene ester of pyrocatechol by the action of dichloromethane (instead of diiodomethane as generally used) on an alkaline salt of pyrocatechol. A mixture of 3 Gm. pyrocatechol, 2.4 Gm. dichloromethane, 1.6 Gm. caustic soda, 0.7 Gm. of water and 9 Gm. ethanol are heated for 15 to 18 hours on the water bath, yielding a dark liquid containing sodium chloride crystals. The liquid was steam distilled, the distillate extracted with ether, the extract washed with caustic soda solution and with water and then dried and the ether was evaporated. The amount of caustic soda used should be about 72% of that theoretically required to combine with the pyrocatechol, the best medium is 96% ethanol and the optimum temperature is 110° to 115° C. The maximum yield obtained was 23.2% of theoretical.—R. L. BACHRACH. *Maslo bojno Zhirovoe Delo*, 9 (1934), 42, through *Chimie & Industrie*, 33 (1935), 137. (A. P. C.)

Trisodium Periodate and Periodic Acid—Preparation of. Fifty grams of sodium iodate, 660 cc. of soda lye (density, 1.332) and distilled water to make up to 2000 cc. are introduced into a pyrex graduated container. The mixture is heated to 80°, stirred, and 80 cc. of pure bromine is introduced. The product is filtered, washed several times with 200-cc. portions of water and then dried. A crystalline compound of trisodium periodate (97–99% pure) is obtained. The periodic acid is prepared by first dissolving a weighed amount of trisodium periodate in excess normal nitric acid. In another container an equivalent amount of silver nitrate is dissolved in water and then the two solutions are mixed. The resulting periodate of silver is washed, placed in a container with water warmed to 70° and bromine is added until a light yellow precipitate results upon agitation. The precipitate is separated, and washed. The washings and mother liquor are combined and evaporated partly with concentrated sulphuric acid, and finally pieces of soda are added. The periodate is removed and appears as a light yellow solid.—J. LANGE and R. PARIS. *J. pharm. chim.*, 21 (1935) 403. (M. M. Z.)

BIOCHEMISTRY

Anterior Pituitary—Studies on the Thyrotropic Hormone of. Changes in metabolic rate of a group of rats injected with large doses of a purified extract of thyrotropic hormone were followed. A rise in metabolic rate occurred during the first week of injections reaching a peak of plus 28 per cent; the metabolism then dropped to the preinjection value by the second or third week and continued to fall going as low as minus 29 per cent by the fifth week. The microscopic appearance of the thyroid at this stage of treatment resembled that of the untreated hypophysectomized animal. The pituitary gland of the animals injected with thyrotropic hormone for a long period of time gave a negative response when tested for the presence of thyrotropic hormone although they still contained the growth hormone. In studying the nature of this apparent resistance to the thyrotropic hormone it was found that the serum of animals which had been injected for a long period of

tune with thyrotropic hormone contained a substance that is capable of inhibiting the action of thyrotropic hormone. The serum from these rats when given in doses of 0.5 to 1.0 cc twice daily for three days to hypophysectomized rats, prevented a rise in metabolic rate with amounts of thyrotropic hormone equal to 200 times the minimum effective dose. A similar finding was obtained when normal rats and guinea pigs were used as the test animals. The injection of thyrotropic hormone to a horse for a period of four months was found to produce the antithyrotropic substance in the horse's serum after the first month. Extracts of the antithyrotropic serum of the horse were prepared which, when given in doses of 0.4 cc, were capable of inhibiting the action of 100 units of thyrotropic hormone in the normal rat. Larger amounts of the extract, up to 4 cc daily, not only inhibited the action of 100 units of thyrotropic hormone injected into normal rats but at the same time apparently inhibited the thyrotropic hormone of the animal's own pituitary gland, causing a fall in metabolic rate to minus 24 per cent, which is the metabolic rate of the hypophysectomized animal. The antithyrotropic substance appeared to be unstable and boiling at p_H 5 for 3 minutes completely destroyed the inhibitory substance. The extract was also found to lose a considerable degree of its potency when kept in sterile ampuls in a refrigerator for two months. When kept at room temperature, the potency was entirely lost after this time. The discovery of this inhibitory substance is believed by the authors to provide the explanation for the numerous negative reports on the clinical use of the thyrotropic hormone. The nature or mechanism of action is discussed.—J. B. COLLIP and E. M. ANDERSON. *J Am Med Assoc*, 104 (1935), 965 (M. R. T.)

Cow's Milk—Antirachitic. Comparative Study of Antirachitic Value of Irradiated Cow's Milk and of Milk Produced by Cows Fed Irradiated Yeast. Thirteen rachitic infants, after a preliminary treatment-free observation period during which the activity of the rachitic process was established, were divided into groups that were fed 720 cc or 480 cc daily doses of cow's milk made antirachitic either by irradiation or by feeding irradiated yeast to cows. The infants were housed in hospital wards or rooms. Roentgenograms were taken weekly and determinations of the calcium, inorganic phosphate and phosphatase levels in the blood serum were made usually every two weeks and only occasionally at intervals of 1 or 3 weeks. On the basis of the data collected in this study, it is concluded that there is for rachitic infants no practical difference in antirachitic efficacy between cow's milk made antirachitic on the one hand by irradiation and on the other by feeding cows irradiated yeast when the same amount of the antirachitic factor is administered, as represented by an identical number of Steenbock rat units per day. The antirachitic factor in both milks in an amount assayed to equal 40 Steenbock rat units per day was able to produce satisfactory healing in the blood in from 49 to 61.7 days and in the bone in from 10.5 to 11 weeks. The antirachitic factor in the yeast milk in an amount assayed to equal 27.5 Steenbock rat units per day also was able to bring about satisfactory healing in the blood and in the bone. However, the period of time required to bring about this result in the blood was on an average 118 days (from 74 to 155 days) and in the bones on an average 21.2 weeks (from 16 to 24 weeks), indicating, therefore, that for the rachitic infants tested in this study the dose of 27.5 Steenbock rat units per day was very close to the actual minimum amount required for the ultimate healing of the active rickets.—H. J. GERSTENBERGER, *et al*. *J Am Med Assoc*, 104 (1935), 816 (M. R. T.)

Ascorbic Acid—Total, Content of Human Blood. Method of Determination. Mix 5 cc of oxalated blood with 5 cc of 10% trichloroacetic acid, shake and add 5 cc 16.6% mercuric acetate. After 5 minutes add 0.25 Gm calcium carbonate and centrifuge. Treat thoroughly with hydrogen sulphide. After 18 hours, remove the hydrogen sulphide with a stream of nitrogen. Use for titration a solution of 2.6 sodium dichlorophenolindophenol (25 mg in 50 cc) so diluted that 12 cc is equivalent to 1 mg of ascorbic acid as determined by a standard. Add 1 cc 10% acetic acid to 5 cc of the hydrogen sulphide-free filtrate and titrate into 0.1 cc of the indicator solution. The values in normal individuals are between 1.19 and 2.66 mg %.—I. ARTHUR MIRSKY, S. SWADESH and S. SOSKIN. *Proc Soc Exptl Biol Med* 32 (1935), 1130 (A. E. M.)

Dietetics—Some Aspects of Acidosis, diabetes, constipation and infant feeding are dealt with briefly in this article.—*Pharm J*, 134 (1935), 259 (W. B. B.)

Ergosterol. By studying the peroxides of ergosterol and dehydroergosterol obtained by the action of oxygen in the presence of light and a sensitizer as well as their transposition products

it has been ascertained that dehydroergosterol has two double bonds in the same position as in ergosterol

M MULLER *Z physiol Chem*, 231 (1935) 75, through *Squibb Abstract Bull*, 8 (1935), A-362

Etrones—Separation of, from Urine Isolation of α -Folliculin from Urine of the Horse The α -folliculin obtained from the urine of the horse m 262° (corrected), $[\alpha]$ 190 in chloroform = +158.4° The hormone is identical with the international standard of folliculin and that from pregnant women The benzoate m 217.5° and on resolidification m 204–205° The color reactions described by Schwenk and Hildebrandt *S A B* 6 (1933), 445 for β folliculin were also obtained with α folliculin and the international standard Both the latter in doses of 0.3 γ in oil solution produced estrus in 8 of 15 rats—V DEULOFEU and J FERRARI *Compt rend soc biol*, 118 (1935) 588, through *Squibb Abstract Bull* 8 (1935) A-464

Ovarian Follicular Hormone—Crystalline The hormone obtained from hog ovaries seems to be identical with dihydro theelin The *m* brombenzoate has a melting point of 154–155°, as compared with 155–156° found with the analogous compound prepared from pure dihydro theelin The hormones obtained by saponification of the latter compounds have an identical melting point of 170–171°—D W MACCORQUODALE, SIDNEY A THAYER and EDWARD A DOISY *Proc Soc Exptl Biol Med*, 32 (1935) 1182 (A E M)

Gastric Secretions The latest biological theory concerning the gastric secretions is that histamine or a salt of it is formed in the wall of the stomach and causes an outpouring of secretion It is probable that histamine is derived from food in contact with the stomach lining The same result would follow from a persistent salt-free diet The present craze of tablet taking is to be discouraged If a tablet of an anhydrous chemical lay in contact with the moisture laden tissue of the stomach it exerts a severe hygroscopic effect Powders are to be preferred over tablets but neither should be taken on an empty stomach The use of sodium bicarbonate in dyspepsia is popular, but fallacious It is useful not in acidity, but when the acid is already low for it dissolves the mucous and stimulates secretion Magnesium hydroxide and bismuth carbonate given a fair time after food are effective in reducing acidity Acids should also be given a fair time after foods—B R BRAMWELL *Pharm J*, 134 (1935) 268 (W B B)

Gonadotropic Hormones A Szarka (*Orvosi Hetilap* Nov 1934, page 1009) using Evan's technique established that by augmenting the anterior pituitary hormone with a hormone prepared from amnion a still greater gonadotropic activity was secured With a modified technique a combination was finally established (0.45 anterior pituitary lobe 0.5 placenta, 0.05 part hemolyzed pregnant blood) which appears to have properties greatly resembling those of the pituitary hormone yet surpassing this in luteinizing activity and differing somewhat from the urinary hormone—*Brit Med J* 3873 (1935), 54 (W H H)

Hormones Endocrinology A survey of the present knowledge of endocrinology is presented This covers the hormones of the thymus pituitary thyroid pancreas parathyroid and adrenals and the sex hormones their source action and clinical use—R DENISON *Pennsylvania M J* 38 (1935), 313, through *Squibb Abstract Bull*, 8 (1935) A-402

Hormones and Lipoids—Separation of Substances containing complex albumin lipid hormone compounds, e g glands gland extracts, blood and aqueous fruit extracts are treated with an organic solvent capable of decomposing the complex compounds e g, alcohol or acetone and also with an adsorbent e g active aluminum oxide active carbon or silica gel, whereby the albumin is precipitated, the lipid is adsorbed and the hormone remains in solution Further concentration of the lipid and the hormone can then be effected in known manner Special

processes are described —G PERITZ and C BRAHM Ger Pat , 608,414, Jan 23, 1935 (Cl 12p 17 10) (S W G)

Insulin—Purification of Method for Precipitation of A 0.2% aqueous solution of potassium ferrocyanide precipitated insulin quantitatively from acid solution since filtrates from such precipitates were entirely inactive and the precipitates contained all the activity as determined by biological tests. Also, the filtrates treated with picric acid gave inactive precipitates which doubtless represented impurities. This occurred even with insulin containing 20 international units per mg. The potassium ferrocyanide insulin precipitate (Ferrinsulin) (I) when prepared from the purest commercial insulins was light blue in the dry condition, but a deeper blue when prepared from more impure commercial preparations. Thus the blue color was due to impurities. I was insoluble in water and dilute hydrochloric acid but soluble in 2% sodium phosphate or ammonium phosphate. This reaction afforded not only a means of purifying insulin but of determining *in vitro* the purity of a given preparation. For example, a sample equivalent to 100 units of an insulin supposed to contain 20–22 international units per mg. should give approximately 5 mg of I. The amount of potassium ferrocyanide needed to precipitate 100 units was less than 1 cc., but excess of the 0.2% reagent had no effect on precipitation. However, with more concentrated solutions of reagent (10%), excess dissolved some of the precipitated I—I I NITZESCU and S SECAREANU *Bull soc chim biol*, 17 (1935) 118, through *Squibb Abstract Bull*, 8 (1935), A-403

Lecithins—Use of, in Nutrition, Etc This review covers the chemistry of lecithins as well as their use in foods, etc. Twenty two papers most of which have been published since 1930 are quoted from at considerable length. Analytical data is presented mostly in tabular form. The compilation of information is both concisely and logically presented —E I VAN ITALLIE *Pharm Weekblad*, 72 (1935), 238–246, 296–304 (E H W)

Liver—Effect of Autolysis on Potency of, in Treatment of Pernicious Anemia Case evidence is submitted which shows that both experimental and commercial autolysates of liver have less hematopoietic activity against pernicious anemia than amounts of liver from which they were derived. This was contrary to the observations of Herron and McElroy reported in 1932 which suggested that autolysis markedly increased the potency of liver in the treatment of pernicious anemia —W B CASTLE and M B STRAUSS *J Am Med Assoc*, 104 (1935), 798 (M R T)

Liver Extract—Charcoal Adsorption as a Method for the Preparation of Concentrated. A method for the preparation of liver extract based on the property of the hematopoietically active principle of becoming adsorbed by charcoal from an acid solution is described. This allows the concentration of the fluid to a small volume without much loss of potency —JEAN L KYER *Proc Soc Exptl Biol Med*, 32 (1935), 1102 (A E M)

Liver Extract—Preparation of The authors give a rather complete history of the use of liver extract. Analyses show the major constituents of liver to be somewhat as follows: water 72.0%, protein (N \times 6.25) 20.4%, fat 4.5%, carbohydrate 1.7%, ash 1.4%. None of these constituents, as such, is of interest in the manufacture of liver extract, but the finer constituents not indicated in such an analysis contain the active material. Cohn and his collaborators proved that the active principle was water soluble, and could be freed from liver protein by precipitation at the isoelectric point. By extracting the residue with ether they then separated all lipid substances, and finally separated an alcohol precipitable fraction. By treatment with basic lead acetate, all carbohydrates were eliminated, and still the active principle remained in the filtrate. The active principle has been shown to be precipitated by phosphotungstic acid and it is suggested that it is probably a nitrogenous base, though not a purine derivative. Investigation reached this point in 1930 and does not seem to have progressed since. The fresh liver, if to be stored for any length of time has to be frozen immediately upon extraction from the animal and held at 20° F or below to prevent deterioration. It is then minced or finely ground and extracted by prolonged agitation with warm water. From the resultant mass, liver protein and heat coagulable protein are precipitated, and the liquor filtered off. The aqueous extract is then concentrated to a sirupy liquid by evaporation under high vacuum and treated with alcohol, which throws down the alcohol-coagulable nitrogenous matter which is filtered off. The alcohol filtrate is concentrated by vacuum distillation, and the concentration is further dried *in vacuo* until the moisture content has been reduced to below 3% —C P CALLISTER and H G OSBORNE *Australasian J Pharm*, 16 (1935), 32 (T G W)

Pituitary—Diabetogenic, Thyrotropic, Adrenotropic and Parathyrotropic Factors of A review of the literature concerning the several physiologic roles exercised by the pituitary —J B COLLIP *J Am Med Assoc*, 104 (1935), 916 (M R T)

Pituitary—Diabetogenic, Thyrotropic, Adrenotropic and Parathyrotropic Factors of 1 Diabetogenic Substance A review of existing evidence relating to the diabetogenic substance of the pituitary —J B COLLIP *J Am Med Assoc*, 104 (1935), 827 (M R T)

Resorcinol (Fructose) Reaction in Cerebrospinal Fluid Roe's method for determining fructose in blood, applied to spinal fluid, gives an average value of 4.1 mg per 100 cc. The reducing substance has the biological properties of fructose. The quantity found is in proportion with the glucose present. It is supposed that a product of rearrangement of glucose, as occurs under the influence of alkali, is responsible for the reaction —ROGER S HUBBARD and HELEN R GARBUTT *Proc Soc Exptl Biol Med*, 32 (1935) 986 (A E M)

Serum Iron—Method for the Estimation of The total iron in the serum is determined by ashing 2 cc with 2 cc of sulphuric acid and 30% hydrogen peroxide. It is diluted to 15 cc with water, oxidized with permanganate and shaken with 5 cc ethyl acetate and 5 cc of a 20% ammonium thiocyanate solution. The color of the ethyl acetate layer is compared colorimetrically with a standard containing 0.005 mg of iron. A blank test must be run besides. The iron corresponding to the hemoglobin dissolved in the serum is determined by the benzidine method. Mix 2 cc of the benzidine reagent with 0.5 cc serum, add 0.5 cc water and 1 cc 0.6% hydrogen peroxide. Prepare another test using 0.5 cc of a standard blood solution containing 0.05 mg of hemoglobin per cc instead of 0.5 cc of water. Reading is done after development of the color in the usual way. The blood protein present prevents full development of the color. The second test serves to determine the percentage of hemoglobin, and a corresponding correction is applied to the first test. Finally, the mg of hemoglobin per 100 cc are computed as micrograms of iron by multiplying by the factor 3.35 —FRANKLIN C BING and RAMON F HANZAL *Proc Soc Exptl Biol Med* 32 (1935) 1013 (A E M)

Sex Hormones—Female A general review is given. The clinical possibilities of follicular hormone (progynon) and corpus luteum hormone (proluton) are discussed —ANTONIO J SCHIAVO *Semana med (Buenos Aires)*, 42, 1 (1935) 819 (A E M)

Sex Hormones I Hormones of the Anterior Hypophysis A brief historical and chemical review of hormone literature, especially the hormones of the anterior hypophysis —C R ADDINALL *Merck Report*, 44 (1935), 4-6 (S W G)

Sex Hormones—Review of A detailed description of the changes involved in the process of menstruation, and a microscopic study of the development of a mature ovary and the stages in the production of a mature ovum is given. The origin and impulse for the profound changes in the uterus were first sought in the nervous system, but it was soon realized that the ovary was the causal factor. There follows a presentation of the several hormones as to their source, production, chemical constitution as far as is known, effects which they produce, and the units for tests which have been established. The hormones taken up are: the follicular hormone, the corpus luteum hormone, the anterior and posterior lobe pituitary sex hormones, other hormones of the pituitary, and the interrelationship of the various endocrine glands. Some results of clinical use of some of the sex hormones are given —R JOACHIMOVITS *Scientia Pharm*, 6 (1935) 25 (M F W D)

Testicular Hormones Clarification of Constitution of Androsterone Explanatory and critical data on the work of R. *et al*, Cook, *et al*, and Butenandt *et al* regarding the structural formula of androsterone. R. *et al* maintain that their synthesis of androsterone is the first unequivocal proof of the derivation of a sex hormone from a sterol —L RUZICKA, M W GOLDBERG and H WIRZ *Helv Chim Acta* 18 (1935) 61 through *Squirb Abstract Bull*, 8 (1935), A 378

Vitamin A—Effects of Cottonseed Meal on Stability of, in Cod Liver Oil Since cottonseed is known to contain antioxidant substances capable of protecting the oil against rancidity, and common experience shows that this protection applies to the residual oil in cottonseed meal, the latter suggests itself as a possible factor in controlling the keeping quality of cod liver oil and in preserving vitamin A in mixed feeds. This preservative effect is obtained in high degree only by intimate mixing of cod liver oil with the meal. Feeding points are described which illustrate this fact —H G MILLER *Oil and Soap* 12 (1935) 51-52 through *Chem Abstracts*, 29 (1935) 2663

Vitamin B A brief review of literature dealing with vitamin B is given. A probable structure of the vitamin B molecule is pictured —ANON *Merck Report*, 44 (1935), 13-14 (S W G)

Vitamin B—Relation of, in Foodstuffs This work deals with the relationship between the B vitamins and the protein fat and carbohydrate content of the food. The author's investigations, conducted with white mice, led him to the conclusion that vitamin B₁ (+B₄) bears a quantitative relationship to the carbohydrate content of the diet, and that vitamin B₂ bears a similar relationship to the fat content of the diet and probably also to its protein content.—P. VOGT-MÖLLER *Lancet*, 228 (1935), 275 (W. H. H.)

Vitamin B₁—Method for Obtaining Vitamin B₁, which has been adsorbed by an adsorption agent such as fuller's earth, may be removed by the use of hydrochloric or sulphuric acid solution of a concentration of at least 5%. Use of alcohol with the acid facilitates the removal, and the acid solution obtained may be partially neutralized to a p_H of 5 to 7.—ELMER H. STUART (to Eli Lilly and Co.) U. S. Pat. 1,990,961, Feb. 12, 1935 (S. W. G.)

Vitamin Standards—International The Second International Conference on Vitamin Standardization adopted pure β carotene as standard for vitamin A, standards for vitamins B and D remain unchanged. *l*-Ascorbic acid has been adopted as standard for vitamin C, unit activity being defined as the vitamin C activity contained in 0.05 mg. of pure *l* ascorbic acid.—*J. Soc. Chem. Ind.*, 54 (1935), 289 (E. G. V.)

Vitamins—Standardization of Report of Second International Conference. At the second international vitamin conference in London (June 1934) the following standards were adopted: vitamin A, pure β -carotene, the international unit being 0.6 γ ; for vitamin B₁, the adsorption product prepared in the medical laboratory of Batavia, the international unit being 10 mg. of this product; for vitamin C, *l* ascorbic acid, the international unit being 0.05 mg.; and for vitamin D, the standard solution of irradiated ergosterol adopted in 1931, the international unit being 1-mg. solution which is equivalent to 0.025 γ crystals of vitamin D.—L. RANDOIN *Bull. soc. chim. biol.*, 17 (1935), 67, through *Squibb Abstract Bull.*, 8 (1935) A-374.

ANALYTICAL

Alkaloidal Drug Extracts—The Air-Lift Extractor Applied to the Analysis of Since extraction of alkaloids from pharmaceutical preparations consumes much time, automatic devices have been suggested, but most of them are unsuitable because they depend on refluxing of the solvent by heat with possible decomposition of alkaloid and because of the difficulty of knowing when extraction is complete. The air extractor operates at room temperature and is provided with a stop-cock so that samples may be drawn off and tested. Following is the method: "The large tube of the apparatus is filled nearly to the overflow with chloroform; the preparation to be extracted is superimposed upon it and made alkaline with ammonia. A small quantity of chloroform is placed in the smaller tube, 40 cc. of 5% sulphuric acid is added and then chloroform until the top of the acid layer is almost to the inlet. The air (or nitrogen) is allowed to enter and extraction continued until all of the alkaloid is deposited in the acid layer. This point may be determined by removing a small quantity of chloroform solution through the stop cock at the bottom of the tube and testing it in the usual manner with Mayer's reagent. About four hours are required for the complete extraction of the alkaloid. The acid is then removed from the tube, the tube rinsed with water and the final extraction made with chloroform in a separator after making the acid solution alkaline with ammonia." A series of extracts checked against the U. S. P. X shows agreement within limits of experimental error.—L. D. SEIF and T. H. RIDER *J. Am. Pharm. Assoc.* 24 (1935), 267 (Z. M. C.)

Alkaloidal Salts—Titration of Use of Porrier Blue as Indicator. The adoption by certain Pharmacopœias of titrimetric methods for the determination of purity and identity of alkaloidal salts led the authors to determine, by titration with 0.1N sodium hydroxide, the equivalence numbers (D. A. B. VI) of 28 alkaloidal salts. Estimations were conducted in different titration media: viz., water, water-alcohol, water-chloroform, chloroform-alcohol, alcohol and acetone, using phenolphthalein and Porrier blue as indicators. The limitations observed in the determination of equivalence numbers by following different titration techniques are discussed. Porrier blue is, in general, a more satisfactory indicator than phenolphthalein because of its sharp end point, but it cannot be used for the titration of all alkaloidal salts. Porrier blue was shown, by analysis of three specimens, to possess a variable composition. Photometric and light absorption studies indicated decided color instability on the alkaline side but greater stability over the acid p_H range.—E. REIMERS *Arch. Pharm.*, 273 (1935) 140 (L. L. M.)

Alkaloids—Quantitative Determination of, with Bromine Previous workers had shown that small amounts of quinine and some other alkaloids could be estimated quantitatively by means of an aqueous bromine solution, the method depending on the absorption of the bromine the end-point being disappearance of yellow color. These reports indicated the method to be inapplicable to atropine, cocaine, morphine, sparteine and some others. In the present study the investigation has been carried further. The general method of procedure is given in detail and also two modifications. Consideration has been given to a number of factors. Time of reaction varies greatly. Addition of chloroform, which may be useful sometimes, requires only a brief time. Addition of apomorphine gives more satisfactory results in cases of very low concentration and the reaction is very rapid. Sulphuric acid accelerates the reaction in some cases. Concentration of bromine solution and of hydrochloric acid as well as concentration of solution to be tested were studied. Volatilization of bromine is negligible with rapidly acting substances but requires consideration for slowly acting ones and means of minimizing this loss are reported. Nature of light and background were considered. Cloudiness in chloroform occurred sometimes from unknown causes so, little valuation can be put upon it. Results presented were based on thousands of test-tube examinations. A short description is given for each of the following: amidopyrine, antipyrine, apomorphine hydrochloride, brucine sulphate, caffeine, codeine sulphate, cinchonidine and cinchonine, dionine, emetine, morphine sulphate, procaine and tutocaine, quinine and quinine strychnine sulphate, theobromine, picrotoxin, salicin, salicylic acid. Koppeschaar's Solution was used and in general the error was about 0.5% in concentrations of about 1-1000. The error in estimation of substances in solutions of unknown concentration increases with the dilution but some may be determined in concentrations of 1-1,000,000 with 5 to 10% error. Estimations are made with controls in which attention must be paid to concentration, temperature, rate of reaction and other factors discussed in the paper.—ROBERT A. HATCHER and ROBERT L. HATCHER. *J. Am. Pharm. Assoc.*, 24 (1935), 262 (Z. M. C.)

p-Aminobenzoic Acid—Determination of Esters of The author describes a method for the gravimetric determination of p-aminobenzoic acid. The acid as such, or that obtained by saponification is diazotized and coupled with beta-naphthol. The resulting substance (beta-naphthol 1-azo-4-p-aminobenzoic acid) which is soluble in water acidified with hydrochloric acid may be collected, dried at 100° and weighed. When the acid must be obtained by saponification (cycloform and novocaine) one boils with sodium hydroxide and separates the resulting impurities from the acid by shaking with chloroform. The alkaline solution or the acid solution (after acidifying) may be thus shaken out. In both cases the aminobenzoic acid remains in the aqueous portion.—I. FLODERER. *Ber. Ungar. Ph. Ges.* (1935), 314, through *Pharm. Weekblad*, 72 (1935) 397 (E. H. W.)

Analytical Methods—Notes on Some, with Special Reference to Their Teaching Value The paper draws attention to some recent methods of volumetric analysis which should be recommended for teaching purposes. Notes are given on the subject of adsorption indicators, such as soluble fluorescein, eosin and dichlorofluorescein. The volumetric method for the assay of sodium sulphate is discussed. For commercial purposes, the gravimetric method seems to be satisfactory but the method of Rivett (*Chem. News*, 118 (1919) 253) serves better as a teaching method. The procedure is as follows: Weigh out about 4 Gm. sodium sulphate, dissolve and add to an excess of recently precipitated barium ovalate, heat on a water bath for 10 minutes. Transfer to a 250 cc. flask, cool, make up to volume and titrate aliquot portions of the filtered liquid. The author advocates the use of titanous sulphate in place of titanous chloride for teaching purposes, as the chloride oxidizes so rapidly.—A. T. S. Sissons. *Australasian J. Pharm.*, 16 (1935) 180 (T. G. W.)

Ascorbic Acid (Vitamin C)—Sensitive Spot Reaction for The principle of the reaction is the reduction of potassium ferricyanide by an acid solution of ascorbic acid and the conversion of the resulting potassium ferrocyanide to Prussian Blue. **Solutions**—(1) 8% acetic acid, (2) ferric sulphate solution. One gram of C. P. anhydrous ferric sulphate is dissolved by boiling with 80 cc. of distilled water and 18 cc. of 85% phosphoric acid. A 1% solution of potassium permanganate is then added dropwise to the appearance of a weak rose coloration. The solution is boiled for several minutes and diluted, after cooling, to 100 cc., (3) 0.4% potassium ferricyanide solution. The ferricyanide must be chemically pure and free from ferrocyanide. **Test**—Macerate several grams of the plant or organ tissue with a two- or threefold quantity of hot 8% acetic acid

in an Eprouvette with a glass tube having a pointed edge. One drop of the acid extract is placed upon a double filter, the second filter paper being used for the test. One drop of the ferricyanide solution is placed upon the filtered drop and then a drop of the ferric sulphate solution is added. In the presence of not less than 0.003 mg. of ascorbic acid per 0.05 cc., a blue coloration is produced within one half minute. If the coloration does not appear within one minute the test must be regarded as negative. Urea does not interfere, sugar solutions interfere only after boiling with alkalis. Large quantities of cysteine, glutathione and pyrogallol interfere, but usually not in the quantities in which they occur in the tissues. In important cases the chemical test should be confirmed by the biological method. For a quantitative determination, cf. H. Tauber and I. S. Kleiner, *J. Biol. Chem.*, 108 (1935), 563.—H. TAUBER *Mikrochem.*, 17 (1935), 111 (L. L. M.)

Carbon Tetrachloride—Determination of, in Chloroform The Danish and Swiss Pharmacopœias are the only two which aim to eliminate the impurity, carbon tetrachloride from chloroform. The amount of carbon tetrachloride is determined as follows. 20 Gm. of chloroform is fractionally distilled in a round bottom flask until there remains only 1 cc. One gram of this is shaken with 150 Gm. of water until completely dissolved. The assay is based on the difference in boiling points of chloroform (60–62°) and carbon tetrachloride (76–77°) and on the difference of solubility in water. The sensitivity of this assay is given by the Danish Pharmacopœia as 2% of impurity. If 3% or more impurity is present, a cloudy liquid is obtained. This method is rapid and effective.—M. E. H. MADSEN *J. pharm. chim.*, 21 (1935), 246 (M. M. Z.)

Castor Oil—Solubility of Distribution Coefficient between Oil and Water of Substances Completely Miscible in Two Solvents The distribution coefficient of methyl alcohol was determined in the system castor oil and water by determination of the alcohol in the water before and after agitating with the oil and was found to be 0.12, a slightly smaller value than that obtained for ethyl alcohol, 0.15. With acetic acid the technique consisted in determining this alkalimetrically and directly in the water before and after agitation with the oil using a *N*/60 solution of sodium carbonate of which 1 cc. corresponded to 1 cc. of acid, with the indicator phenolphthalein. The coefficient of distribution of acetic acid remained constant for a given concentration and varied little but irregularly with the concentration. At 0.1–0.25%, the value lay between 0.216 and 0.239, and at 10% was equal to about 0.2. Thus the values for the distribution coefficient of acetic acid and methyl alcohol are not similar, though both possess the characteristic of miscibility with water and with castor oil.—A. LINDENBERG *Compt. rend. soc. biol.*, 118 (1935), 441, No. 5, through *Squibb Abstract Bull.*, 8 (1935), A-459.

Chromium Pigment—Micro-reaction of Chromate and bichromate give a violet coloration passing over to red with a 1% solution of strychnine in concentrated sulphuric acid. Tri-valent chromium ion must be oxidized to chromate before the color test is given. Hydrogen peroxide may be used as the oxidant. The reaction is carried out by the spot method. The limit of sensitivity is 0.98 microgram CrO_4^{2-} corresponding to 0.348 microgram of chromium. Interfering ions are manganese, cobalt, ferricyanide and ferrocyanide, although their effects may be removed by suitable precautions.—S. AUGUSTI *Mikrochem.* 17 (1935) 17 (L. L. M.)

Citrus Oils—Value of Ultraviolet Fluorescence as Test for Determination of Substances Producing the Fluorescence An attempt recently made by E. Bottini to determine the substance or substances responsible for the magnificent fluorescences shown by citrus oils exposed to ultraviolet light and examined under suitable conditions. His results are presented in *Annali della Sperimentazione Agraria*, 15 (1934), 61–78, published in Rome. He gives brief descriptions of the colors excited by ultraviolet rays falling upon intact fruits of orange, lemon, mandarin, bergamot, cedrat and grapefruit. His principal interest was to trace the substances responsible for the fluorescence, and for this purpose he used the pure essential oils of mandarin, sweet orange, bergamot and lemon at three concentrations: undiluted, and diluted with absolute alcohol to contents of 0.17 and 0.0034 per cent of oil. Spots on porcelain showing the various colors are listed. The next step was to place drops of the same four oils at the same three concentrations upon filter paper and to examine their fluorescence in that condition. The colors thus obtained were not quite the same as those obtained upon porcelain, owing to the varying diffusibilities of constituents of the oils. He discusses the substances responsible for the intense blue fluorescence of the four oils named when these are examined under ultraviolet light. This report is of special interest to perfumers.—HUGH NICOL *Perf. and Ess. Oil Rec.*, 26 (1935), 85 (A. C. DED.)

Copper—Modified Iodimetric Method of Determining The weighed sample of copper is

dissolved in nitric acid, 5 cc of 6*N* sulphuric acid is added and nitric acid removed by evaporation. After dissolving in 20 cc of water, 2-3 Gm of potassium iodide is added and the titration with sodium thiosulphate carried out as usual till most of the free iodine is exhausted. After adding starch solution, the titration is continued nearly to the end point and approximately 2 Gm of ammonium thiocyanate is added and dissolved by thorough stirring. The blue color deepens. Titration is continued to a sharp end-point, the precipitate turning white.—H W FOOTE and JOHN E VANCE *J Am Chem Soc*, 57 (1935), 845 (E B S)

Copper—Potentiometric Estimation of The estimation of copper in the form of copper sulphate in sodium acetate acetic acid buffers previously described (*J*, 10 (1932), 41) can be carried out without the addition of free acid. This obviates the judging of the proper amount of acid to be added before titrations. The most suitable range for making up the copper sulphate solutions is between p_H 3 and 6. Above p_H 6, the error rises rapidly. The potentials at the end point have been found to rise with the p_H .—C PRASAD and J B JHA *J Indian Chem Soc*, 12 (1935), 1, through *Squibb Abstract Bull*, 8 (1935) A-501

Copper—Use of Potassium Stannous Chloride in the Volumetric Determination of A volumetric method of determining copper is described. The method is based upon the reduction of the copper in hydrochloric acid solution in the presence of sodium bicarbonate (to produce an atmosphere of carbon dioxide) with an excess of potassium chlorostannite and titrating the excess reagent with 0.1*N* iodine solution. The error in the determination of 0.02 Gm of copper as copper sulphate was 0.4%.—EMM VOYATZAKIS *Bull soc chim, mem* (5), 1 (1934) 1356, through *Squibb Abstract Bull*, 8 (1935), A 532

Cupric and Ferric Ions—*p*-Aminophenol Hydrochloride as a Reagent for A 2% alcoholic solution of *p* aminophenol hydrochloride gives with cupric and ferric salts a blue-violet precipitate. The reaction may be applied macro or microchemically (as a spot method). As limits of sensitivity were found: Cupric ion macromethod 0.15 mg, micromethod 0.2γ, Ferric ion macromethod 0.013 mg, micromethod 0.069γ. Other ions do not interfere. The coloration is intensified by acetic acid. The precipitates are apparently complex salts.—S AUGUSTI *Mikrochem*, 17 (1935) 118 (L L M)

Derris Root—Determination of Rotenone Content of A critical study of the polarimetric method of Danckwörtt and a modified Roark method. The former gives the lower values. In the opinion of the author a standard method worthy of adoption has not appeared as yet.—P A ROWAAN *Arch Pharm* 273 (1935), 237 (L L M)

Diothane Solution—Stability of II It was reported previously that prolonged aging or heating of diothane solutions caused slight decomposition, the substance formed being either an aminobenzoate formed by rearrangement or aniline formed by hydrolysis. A detailed study of the hydrolysis of diothane using alcoholic potash has shown that aniline is formed. When diothane solutions are diazotized and coupled with beta-naphthol, the color is concentrated upon the precipitate of diothane free base so that small amounts are detectable but quantitative color comparison is difficult. The standard colorimetric procedure for aniline (use of bleaching powder) proved inapplicable. Color was not sufficient for quantitative comparison when the reaction was potentiated with phenol. A diazotization has been developed using H acid instead of beta

naphthol. Carried out in presence of alcohol it proved very sensitive, concentrations as low as 1/10,000,000 can be detected qualitatively. Details of procedure are given and results of a number of experiments are tabulated and discussed. It was found that maximum concentration produced by sterilization is 1/20,000 in unacidified solution, 1/30,000 in acidified. Ordinary solutions show 1/350,000, too slight a change to affect potency. Addition of acid inhibits formation of aniline. So long as diothane solution is colorless and clear anesthetic potency is unchanged. If cloudy or colored it should not be used.—E S COOK, K BAMBACH and F H RIDER *J Am Pharm Assoc*, 24 (1935) 269 (Z M C)

Drugs—Quality of In a report from the government medical stores at Amsterdam covering the year 1934 the author states that most of the samples examined met the required standards.

About a score were rejected. Some of the samples were as follows: Aniline—too low a boiling point, potato starch—20.2% water (max. allowed 16%), lactic acid—sp. gr. too low (1.197), low grade, sodium acetate—sublimation test gave a precipitate, the permanganate test remaining negative, aqua ammonia (25%)—contained lead, ether for anesthesia—gave a strong Nessler reaction even though the ether was preserved with copper, benzol—sp. gr. too low (0.881), $N_{20}^D = 1.501$, contains carbon disulphide and thiophene, magnesium carbonate—contained too much calcium, reduced iron—contained zinc, powdered iron—contained copper and arsenic, bismuth subgallate—contained too much nitrate, calcium sodium and potassium, gelatine—several samples were refused on positive sulphur dioxide reactions, papaverine hydrochloride—contained morphine, oil chaumoogra—rotation, etc., was satisfactory but the oil was not soluble in two volumes of absolute alcohol, oil gaultheria—was methyl salicylate, zinc oxide—contained lead, pastilles mercury oxycyanate—underweight, mercuric cyanide content 40.7% (req. 41%), tin (powdered) and tin oxide—contained lead, aluminum sulphate—did not meet the solubility requirement in water, talcum—contained 16% hydrochloric acid soluble material. The author also discusses the methods of analysis used.—T. ROSEBOOM *Pharm. Weekblad*, 72 (1935), 392.

(E. H. W.)

Dulcin Sweetening Agents. II—Microchemical Studies of The authors compiled a table of the solubility of dulcin in different liquids from the literature reports and from determinations made by themselves. They determined solubilities in trichloroethylene, tetrachloromethane, dichloroethylene, ethyl ether, petroleum ether and in mixtures of trichloroethylene with methyl alcohol and ethyl alcohol. The Jorissen reaction is inhibited by fats and resins such as exist in beer and is made uncertain by the use of lead peroxide which, in large quantities, masks the color developed and which, in small quantities, is responsible for a violet coloration. Cerium acetate and benzoyl peroxide were found to be superior to lead peroxide as oxidants. For the detection of dulcin, the following procedure was followed: One hundred cc. of the suspected liquid are clarified with 10 cc. of saturated copper sulphate solution and 20 Gm. of dry slaked lime, after which the precipitate is filtered off and washed with about 30 cc. of water. The filtrate is neutralized with acetic acid, made slightly alkaline with excess sodium hydroxide, again filtered, then extracted three times with 50 cc. of ethyl acetate, the aqueous layer having been saturated with sodium chloride before the last extraction to salt out the dissolved ethyl acetate. The ethyl acetate is removed by distillation, the residue dissolved in 2–3 cc. of alcohol and the solution, which has been transferred to a small evaporating dish, is mixed with a knife point of yellow lead oxide. The mixture is taken to dryness on a water-bath, then stirred with a glass rod and finally dried again on the water-bath. The powder thus obtained is extracted with three 5-cc. portions of ether, the combined ether extracts are filtered, the filtrate is collected in a test-tube and evaporated to dryness. The residue is warmed with 1 cc. of water and 3 drops of Jorissen's reagent (4 Gm. yellow mercuric oxide dissolved in diluted nitric acid and to which diluted sodium hydroxide is added to form a distinct precipitate, the filtrate from the mixture being diluted to 25 cc.) are added. The solution is heated 3 minutes on a water-bath and 2 drops of cerium acetate solution are added (the acetate solution is prepared by dissolving 1 Gm. cerium nitrate or sulphate in acidulated water, then precipitating with excess ammonia, infusorial earth is added, the solids filtered off and washed well with water, the precipitate and filter are treated with 2–3 cc. acetic acid, filtered and diluted with the washings to make 50 cc.). In the presence of dulcin, a violet coloration results. Very often a yellow precipitate comes down on heating the test sample with the mercuric nitrate, in such cases it is advantageous to filter hot through a Witt plate and test the filtrate for dulcin. It is helpful also to add a drop of diluted acetic acid, whereby a portion of the precipitate remains dissolved and the reaction is more distinct. Benzoyl peroxide is a somewhat less sensitive reagent for dulcin than is cerium acetate. Heating dulcin in glacial acetic acid saturated with potassium nitrate gives a non-specific yellow coloration.—V. STANEK and P. PAVLAS *Mikrochem.*, 17 (1935), 22.

(L. L. M.)

Elektrargol, Kollargol, Argyrol and Protargol—Identification and Differentiation of Add 1 cc. of a 10% solution of sodium iodide to 2 cc. of the unknown solution, and then add 5 cc. of water and 10 drops of a 10% solution of salt-peter, and then add to this a solution of ammonium molybdate. The following results are noted: in the case of Kollargol, a reddish brown precipitate forms which changes immediately to dark blue; this color can be noticed in the supernatant liquid even after the precipitate has settled. With the same procedure we get a brown flocculent

precipitate with Argyrol which changes after 1 minute to bluish green and the supernatant liquid remains yellowish green. In the case of Protargol, the precipitate is yellow and sets much slower than in the case of Argyrol and the supernatant liquid is orange yellow. If sodium chloride or sodium bromide is used in place of sodium iodide then the colors of the precipitates are different and can be told apart among the samples used. Elektrargol can be told apart from Kollargol in that it does not change on the addition of a few drops of concentrated sulphuric acid while with Kollargol we get a brownish red precipitate. On addition of potassium persulphate to the Kollargol precipitate, we get a violet precipitate which finally dissolves, while the brownish solution of Elektrargol becomes a clear yellow solution. Further identity tests are given in the original article.—G CONSTANTINESCU *Curierul farm*, 4 Nr 9 (Sept 1934), 4-8, *Chem Multarzentralb*, through *Chem Zentr*, 106 (1935) 929 (G B)

Ether—Reaction for Peroxide in If 1-2 cc of ether is allowed to evaporate in a porcelain dish and 1 drop of alcohol, 1 drop of benzaldehyde and 1 drop of strong sulphuric acid added, an eosin red color will be developed if peroxide is present.—A CASTIGLIONI *Ann Chim appl Roma*, 24 (1934), 209, through *Pharm Weekblad*, 72 (1925), 336 (E H W)

Ethereal Oils—Estimation of, in Drugs An apparatus for the rapid approximate determination of ethereal oils in drugs is described. Twenty to 30 Gm of the drug is boiled for one

hour with 200 cc of water. The steam containing the oil is condensed in a reflux condenser the condensate being collected in a measuring cylinder calibrated to $\frac{1}{20}$ cc. The volume of ethereal oil obtained is read off and converted by use of the average density of the oil to percentage by weight. The apparatus was found to give satisfactory results. Several sources of error are retention of droplets of oil in the lower part of the condenser, emulsification of the oil in water, and differences in the shapes of the upper and lower meniscus of the oil layer. If the content of oils determined by the Geyer apparatus is 10% more than the required oil content, the drug may be assumed to be in conformity with the official requirement, otherwise the more accurate D A B VI method must be used.—P HORKHEIMER *Pharm Ztg*, 80 (1935), 148 (G C C)

Ethyl Phthalate—Determination of, in Essential Oils by Potassium Phthalate Method Walbaum and Rosenthal have given a method for the determination of ethyl phthalate, based on saponification with caustic potash, filtering, drying and weighing the insoluble potassium phthalate, but did not specify the conditions of carrying out the determination nor the possibilities of interference by other substances. A plea is made for investigation of the reaction.—SEBASTIEN SABETAY *Ann Fals*, 28 (1935) 100-102 (A P C)

Extract of Malt The British Pharmacopœia directs that Malt Extract be made by extracting malted barley with water at a suitable temperature, and evaporation of the liquid under reduced pressure at a temperature not exceeding 55° C, until a viscous product is obtained. It is evident that an extract is desired in which the activity of the diastase has been preserved, but the Brit Phar does not set any standard for diastatic activity. Malt Extract intended for consumption in Australia, however must comply with the Pure Food Regulations of the various states. The diastatic activity in all the states is to be such that 100 grains of extract will convert 250 grains of potato starch into maltose in 30 minutes at 40° C. The Malt Analysis Section of the Analytical Investigations Committee of the Australian Chemical Institute, has incorporated in the regulations an improved method for this determination of the diastatic activity. The chief points in this method are the use of soluble starch the control of the pH of the solution undergoing digestion by means of ammonium acid phosphate an iodimetric method for estimating the sugars. It is doubtful, however, whether the standard for diastatic activity has any value, as analysis indicates that the action of this enzyme is almost completely inhibited at hydrogen ion concentrations prevailing in the digestive tract.—F ROSENBLUM *Australasian J Pharm* 16 (1935) 173 (T G W)

Gas Analysis—Micro Heat Conductivity Apparatus for Principles and construction of apparatus are explained and illustrated by diagrams.—P GROSS and H STEINER *Mikrochem* 17 (1935), 43 (L L M)

Glycerol—Determination of, in the Presence of Sugars, by Means of Periodic Acid Periodic acid reacts with glycerols oxidizing them to formaldehyde and formic acid, however since

periodic acid attacks sugars as well, it is necessary to first eliminate the sugars. With amounts of sugars such as 1-2% saccharose or 10% glucose, 1 Gm. of barium hydroxide is placed in a 50-cc flask with 5 cc. of the glycerol sugar solution, and the mixture placed in an ice chamber for two hours. This volume is then made up to 50 cc. with 95% alcohol, when a precipitate forms, and the flask again placed in the ice chamber for 15 to 20 hours. The mixture is then centrifuged for 2 or 3 minutes, and 25 cc. of the clear supernatant liquid is then withdrawn. This liquid contains the glycerol and very little sugar. The excess barium hydroxide is removed with 20% sulphuric acid and 25 cc. distilled water. This is heated at 95° until the volume is reduced to 20 or 25 cc. The solution is then neutralized with *N*/10 sodium hydroxide. The glycerol can be determined as follows: 5 cc. of the solution is made acid with 5 cc. of *N*/10 periodic acid. Five to 10 cc. of bicarbonate solution is added, as well as 15 cc. *N*/10 arsenous acid solution and a small amount of potassium iodide solution. The excess of arsenous acid is titrated with *N*/10 iodine. A method of calculation of glycerol, as well as a list of results checking this method are given. Where no sugars are present only the latter procedure is necessary for determining the glycerol.—P. FLEURY and M. FATOME. *J. pharm. chim.*, 21 (1935), 247. (M. M. Z.)

Hexamethylenetetramine—Determination of, in Its Anhydromethylene Citrate. The method is based on the solubility of hexamethylenetetramine in chloroform. Neutralize 0.344 Gm. hexamethylenetetramine anhydromethylene citrate with caustic soda in anhydrous methanol in presence of phenolphthalein. Add chloroform during neutralization, sodium anhydromethylene citrate precipitates, while hexamethylenetetramine remains in solution in the chloroform, after neutralization filter, extract the liquid several times with chloroform to obtain a total of 20 cc. of solution, evaporate the latter to dryness, dissolve the residue in 10 cc. of water, add 50 cc. of decinormal acid, boil 30 minutes, and titrate the excess acidity with decinormal alkali.—M. J. SCHULTE. *Aan P. van der Wielen* (1934), 99-108, through *Chimie & Industrie*, 33 (1935), 677-678. (A. P. C.)

Homeopathic Preparations. VI. Evaluation of Saponin-Containing Tinctures. Saponins are characterized briefly. Homeopathic saponin-containing tinctures are tested qualitatively and quantitatively for saponins. A table of 80 drugs is given, listing for each drug the part official, name of saponin, time for complete hemolysis, hemolytic index and characteristic constituents other than saponin. Frothing, hemolysis and the cholesterol reaction are used to test for saponins qualitatively. The hemolysis test is applied to tinctures as follows: the tincture is evaporated to dryness *in vacuo* and brought to the original volume with physiological salt solution. Defibrinated cattle blood is diluted 1 to 30 with physiological salt solution. Five cc. of this blood solution is mixed in a test-tube with 5 cc. of the alcohol-free tincture. The time for complete hemolysis is measured. A 0.1% solution of pure white saponin (Merck) is used as a control. All hemolysis tests are repeated after shaking out the saponin solution with a 3% acetone solution of cholesterol, these tests should be negative. Primary homeopathic tinctures and triturations of fresh plants with sugar are prepared and their saponin content determined. Results, recorded in a second table, show that the use of diluted alcohol in preparing tinctures increases the saponin content of extracts. The hemolytic index of extracts prepared with 25% alcohol is invariably raised.—A. KUHN and G. SCHAFER. *Pharm. Ztg.*, 80 (1935), 257. (G. E. C.)

Hydrocyanic Acid—Determination of, in Plants. Hydrocyanic acid probably never occurs free in plants, but is combined with a sugar residue and an aldehyde or ketone to form a glycoside. The determination of the acid involves the decomposition of the glycoside and the separation and estimation of the acid. Only about 20% of the total glycoside is thus hydrolyzed. A suggested method is given involving the complete hydrolysis of the glycoside. The method employed has been to supply the deficiency of enzyme by the addition of emulsin taken from the sweet almond. The sweet almond is ground to a fine powder and tested before use for the presence of hydrocyanic acid by means of sodium picrate paper. The plant material is cut up with scissors or ground to a coarse powder. A quantity up to 20 Gm., depending upon the amount of acid thought to be present, is weighed, transferred to a distilling flask, the side tube of which is closed by a short piece of rubber tubing. About 250 cc. of distilled water and 5 Gm. of powdered almonds are added. The flask is stoppered and allowed to remain 24 hours at room temperature, and the contents are steam distilled, the distillate being collected in 100 cc. of 1% sodium hydroxide solution. After two hours, all the hydrocyanic acid is removed, and about 600 cc. of distillate have been collected. This is rendered slightly acid with concentrated hydrochloric, excess of sodium bicarbonate is

added, and the liquid titrated with standard iodine solution—H FINNEMORE and C H WIL
LIAMS *Australasian J Pharm*, 16 (1935) 40 (T G W)

Injections—Hydrogen-Ion Concentration in The disadvantage of colorimetric methods for determination of hydrogen ion concentration or p_H is that one person can match colors more accurately than another, and the presence of coloring matter in the substance of which the p_H value is to be determined causes difficulty, although there is a compensating apparatus for use in such cases. The electrolytic method is much more accurate and gives the correct p_H to two places of decimals. The p_H is of great importance in the preparation of pharmaceutical products. Insulin must be extracted in acid solution—it is destroyed if it comes in contact with pancreatin. If the p_H is kept just below 7 (slightly acid) adrenaline can be boiled and autoclaved, but if the p_H rises above 7 (alkaline) oxidation may set in, a color develop and finally a precipitate. Apomorphine oxidizes if the p_H is higher than 7 and a green color appears. A number of glucosides, such as strophanthin and digitalin are stable at about the point of neutrality, but on either side of this the rate of hydrolysis is increased. In sterilization p_H is important. The factors which affect the well-being of bacteria are food supply of water temperature and p_H . The p_H of the media in which bacteria are to be grown must be carefully adjusted. Some substances are best kept slightly alkaline while others are best kept in the acid condition—H BERRY *Pharm J*, 134 (1935), 214 (W B B)

Iodide Ion—Microchemical Investigation of The iodide ion may be detected by the two following spot reactions. (1) With an ammoniacal solution of mercuric ammonium nitrate (reagent of Cusa and Termi, 10 Gm of mercuric nitrate dissolved in 50 cc of water and 5 cc of nitric acid, with 60 cc of concentrated ammonia water then added to the mixture). A yellow or orange yellow precipitate is produced in the presence of iodide ($Hg_2N I$). The limit of sensitivity is 0.22% of iodine. (2) With a diluted solution of sodium hypochlorite and a 1% solution of magnesium sulphate (reagent of S Augusti) a brown precipitate is produced. The limit of sensitivity is 9% of iodine—S AUGUSTI *Mikrochem*, 17 (1935), 113 (L L M)

Lard—Estimation of the Water Content of Various methods are considered with respect to ease of execution and rapidity. A suitable method for the rapid and approximate determination of the water content of lard is as follows. On solution of a 1.0-Gm sample in 5 cc of benzene at 20° C, lard containing up to 0.5% water gives a clear solution, lard containing 0.6% water gives a slightly turbid solution. Lards containing larger amounts of water give greater turbidity and lard containing 1.0% water gives a heavy milky turbidity—FRIDA GRAF *Scientia Pharm* 6 (1935), 42 (M F W D)

Lead—Identification of, in Pharmaceutical Preparations The weaknesses of several methods of determining lead qualitatively are pointed out. The method suggested by the authors depends upon the oxidation of the lead salt to lead dioxide which will give an intense blue color with an acetic acid solution of benzidine. Procedure. A drop of the solution to be tested is absorbed in filter paper. A drop of 3N sodium hydroxide added, then a drop or two of saturated bromine water, about two drops of ammonia solution (1:1) to destroy the excess oxidizing agent and the excess ammonia expelled by fanning over a flame and finally a drop of acetic acid benzidine solution is added. A deep blue color develops in the presence of lead. The test is sensitive to one microgram of lead or a dilution of 1 to 50,000. For more dilute solutions the test is altered as follows. About 10 cc of the solution to be tested are treated with 3 cc of sodium hydroxide. 2 cc of bromine water, the mixture boiled and filtered through a quantitative filter, the filter washed with ammonia water then with hot water and an acetic acid solution of benzidine is dropped on. In the presence of 10 micrograms of lead in 10 cc or a dilution of 1 to 1,000,000 a definite blue color is obtained. The higher oxides of manganese and cerium would produce the same result, however these ions are not dissolved by the alkaline medium and they will not interfere. Thallium, if present could give the same color reaction. To test for lead in organic compounds the preparation is ashed, the ash dissolved in nitric acid, the solution evaporated to dryness and the residue warmed with water and sodium hydroxide. The solution cooled, dropped on filter paper and the test completed as above. To test for lead in bismuth preparations the residue from ignition is dissolved in nitric acid, the solution evaporated, the residue boiled for two minutes with sodium hydroxide which converts bismuth salts to compounds probably of the formula $BiO(OH)$ then one or two drops of the supernatant liquid are absorbed in filter paper and the test carried out as before—F FEIGLE and A SINGER. *Scientia Pharm*, 6 (1935), 37 (M F W D)

Liquid Preparations—Scheme for the Identification of the Simple, of the British Pharmacopœia. The author gives a detailed description of a scheme, and charts by which many of these preparations can be identified —E M WATSON *Australasian J Pharm*, 18 (1935), 176 (T G W)

Meconic Acid—Colorimetric Determination of, in Opium by Means of Gradual Photometer. Separate meconic anhydride from powdered opium by Haas's method by precipitation as lead meconate which is redissolved in 100 cc of decinormal hydrochloric acid (use 0.75, 0.5 or 0.35 Gm opium so as not to exceed the solubility of meconic acid in dilute hydrochloric acid), to 10 cc of the solution add 10 cc of water and 5 drops of 5% ferric chloride solution, compare the solution in a gradual photometer with a standard solution of meconic acid treated with the same quantity of ferric chloride. The light used is filtered through a green S53 filter. The accuracy of the method is of the order of 0.1% —C G VAN ARKEL *Aan P van der Wielen* (1934), 109-116, through *Chimie & Industrie*, 33 (1935), 675 (A P C)

Medicinal Agents—Standardization of III Particle Size and Degree of Dispersion of Important Medicinal Agents. Many physico-chemical properties of drugs are being more widely adopted as criteria of therapeutic value. Solubility and solution and absorption rates in the organism are dependent upon degree of dispersion. Another important consideration is the rapid increase in total particle surface as degree of dispersion is raised. Surface area determines the therapeutic utility of calomel, mercuric oxide, medicinal charcoals and clays. Cross sections, volumes and masses of individual particles, number of particles per mole and total surface area per mole are tabulated for a number of compounds either from direct measurement or by computation, m_2 , calomel, mercuric oxide, white precipitate and zinc oxide. Degree of dispersion was calculated from particle size (microscopic measurement) and experimentally determined values for specific gravities. Smaller particles of calomel having greater total surface area, are obtained than by the usual methods of production by chilling the vapors of sublimate suddenly. Likewise mercuric oxide is obtained in smaller particles by precipitation than by heating mercuric nitrate in the presence of metallic mercury. In the case of either compound, there is a parallel between particle size and pharmacological activity. Various existing methods for the determination of particle size within the colloidal range are summarized. Protargol (Bayer), silver proteinate (Heyden), Kollargol (Heyden), colloidal silver (Hageda), Lyogen (Byk Guldenwerke), Liquor Aluminii Acetici (D A B VI), Liquor Ferri Aluminati (D A B VI), and Liquor Ferri Oxichlorati dialysati were investigated by the method of Siedentopf and Zsigmondy —R DIETZEL and K SAXHOLM *Arch Pharm* 273 (1935), 170 (L L M)

Methanol—Methods for Detection and Determination of, in Natural Media and Liquids. A critical review and study of existing methods for the oxidation of methanol and determination of the formaldehyde formed proved conclusively that conversion into formaldehyde is not quantitative, nor is it a constant fraction of theoretical yield, and that under certain conditions some formaldehyde is formed from ethanol. All existing methods are therefore unreliable for the quantitative determination of methanol, especially in presence of much larger amounts of ethanol (as most frequently occurs in natural media and liquids), but some of them are satisfactory for its qualitative detection. A new method based on essentially new principles has been developed and will be described in a subsequent publication —MICHAEL FLANZY *Ann Fals*, 28 (1935), 146-158 (A P C)

Microscopic Objects—New Method for Picking, Out of Water. The method devised by Don Ernesto Caballero Bellido for the handling of diatoms under the microscope, which is suitable only for dried particles and therefore unsuitable for protozoa and the like, has been modified to make it applicable to the latter cases. Instead of using a single hair, a pair of microscopic 'tweezers' (called a 'microlab') is constructed by properly attaching two fine hairs to the end of a copper wire so that they project not more than 2 mm beyond the end of the wire. The technique of the preparation and use of the 'microlab' and the auxiliary equipment which has been devised in connection therewith, are described in detail —VENANCE *Naturaliste Canadien*, 62 (1935), 142-147, 153-164 (A P C)

Mineral Pigments—Systematic Method for Microchemical Identification of. The method of differentiation is based upon the differences in behavior of the test samples with diluted nitric acid and upon the usual microchemical reactions for lead, calcium, etc. The following pigments were considered: white lead, chalk, zinc oxide, gypsum, lithopone, lead sulphate and barium sulphate —S AUGUSTI *Mikrochem*, 17 (1935), 1 (L L M)

Morphine—International Method for Its Determination in Opium A criticism of the method proposed by the International Commission of the League of Nations Grinding followed by screening may cause trouble in the case of moist opium In the assay of the extract adsorption of soluble substances by the insoluble residue can cause a loss, on the other hand, the extract, which contains an excess of lime, will absorb carbon dioxide during evaporation, the resultant errors, however, are of little importance No indications are given regarding the purity of the lime, it should be freshly slaked Use of sintered glass filters is unnecessary, as special filter paper is available for vacuum filtration The crystals which adhere to the cork stopper must be taken into consideration The morphine crystals on the filter should be washed with 10 cc of benzene to remove traces of codeine moreover, it is advisable to carry out the reaction in centrifuge tubes, the insoluble matter being separated by centrifuging and the determination carried out on an aliquot of the clear liquid, thus reducing the danger of adsorption —E C M J HOLLMAN Aan P van der Wielen (1934), 117-129, through *Chimie & Industrie*, 33 (1935), 678

(A P C)

Nitrogen—Simple Method for the Determination of The method can be used for various nitrogenous substances As applied to soil the procedure follows 10 Gm of soil are weighed into a flask of about 1 liter capacity Potassium dichromate (about 5 Gm) and mercuric oxide (about 2 Gm) are added and the mixture is treated with 15 cc of water Concentrated sulphuric acid (30 cc) is then added in convenient instalments with frequent shaking A liberal quantity of glass or quartz beads is added to the contents of the flask, which is fitted with an air or water cooled condenser and heated to gentle boiling for 30 minutes The digest is treated with 5 to 7 Gm of pure zinc dust, diluted to about 200 cc and boiled for 10 minutes It is then cooled and distilled with excess of alkali in the usual way —Y V NARAYANAYYA and V SUBRAHMANYAN *J Soc Chem Ind* 54 (1935), 106T

(E G V)

Ointments and Similar Preparations—Qualitative Examination of, by Means of Filtered Ultraviolet Light Rapid and simple qualitative tests could be made The natural colors and colors observed in ultraviolet light of 32 preparations of ointments in the Pharm Hung IV are reported Many commercial samples showed deviations from official prescriptions —ENDRE J Kocsis *Magyar Gyógyszeresstud Társaság Értesítője*, 11 (1935) 99-106, through *Chem Abstracts*, 29 (1935), 2303

Olive Oils—Fluorescence of Influence of Pigments Olive oils, both "virgin" and refined, contain a group or constituent which produces a blue fluorescence under the action of Wood's light (filtered ultraviolet light of λ approximately 3650Å) There are also pigments, either pre-existent (in virgin oils) or added intentionally (in recolored refined oils) which produce an orange or red fluorescence which is superposed to the first-mentioned fluorescence Pigments (chlorophyll, xanthophyll, carotene, etc) have a decided absorbing effect on the fluorescence produced by the oil The fluorescence of any given oil is due to a superposition of the three above phenomena It is concluded that examination by ultraviolet light can be of some use as a rough sorting test, a decided blue fluorescence can be taken as proof that the sample is a refined oil, but otherwise no definite conclusion can be drawn from the test —J GUILLOT *Ann Fals*, 28 (1935), 75-78

(A P C)

Potassium Ion—Detection of, with "Gardinol W" This reagent an alkyl acid sulphate to which is assigned the formula $\text{SO}_3\text{OH C}_n\text{H}_{2n-1}$, gives a positive test for the potassium ion, but is less sensitive than sodium cobaltic nitrite —B REICHERT *Arch Pharm* 273 (1935), 232

(L L M)

Quinaldine Acid as a Micro-reagent. II Estimation of Copper and Its Separation from Cadmium, Manganese, Nickel, Cobalt, Etc Phosphoric, arsenous and arsenic acids do not interfere with the estimation if the washing is carried out as described under the macro method (*Zschr Analyt Chem*, 95 (1933) 400) The micro procedure was as follows The micro beaker and the filter stick, dried at 125° C was weighed in a Kuhlmann's microbalance A tiny crystal of copper sulphate was then introduced into it and the beaker with the stick weighed again The crystal was dissolved in 1-2 cc of water and the solution was acidified with one drop (0.025 cc) of 0.5-0.7N sulphuric acid The beaker was then warmed on the water-bath, and to the hot solution of the reagent (1 per cent solution of recrystallized quinaldine acid) was added one drop at a time in the beginning gently rotating the beaker by the hand after the addition of each drop of reagent, and not adding the second drop till the crystals of quinaldinate settled to the bottom

When the precipitation was complete four drops of the reagent were added in excess, this amount being independent of the amount of copper present. The precipitate was allowed to settle for five to ten minutes by keeping the micro beaker in its stand on the water bath. The supernatant liquid was then drawn off through the filter stick, and the precipitate washed six times by decantation with hot water, keeping the beaker on the water bath all the time. Care should, however, be taken that no precipitate enters the filter-stick before the washing is complete, as the fine precipitate often chokes the filter, delaying filtration. Finally the contents of the beaker were sucked dry through the filter stick, and the beaker with the filter stick was then dried at 125° for 10-12 minutes in a slow current of hot air in the Benedetti Pichler drying apparatus. The beaker with the filter stick was afterward weighed in a microbalance with usual precautions. In an appended table the range of error is shown to be from -0.9 to $+0.75$ per cent.—P. R. RAY and J. GUPTA *Mikrochem.*, 17 (1935), 14 (L. L. M.)

Quinaldinic Acid as a Micro-reagent I Estimation of Zinc, and Its Separation from Manganese. The procedure followed was a micro adaptation of the macro method by the same authors (*Ztschr. Analyt. Chem.* 95 (1934) 400) for the estimation of zinc in the presence of manganese, magnesium, alkaline earths, phosphoric and arsenic acids. *Microestimation*—About 0.6-0.7 mg. of potassium zinc sulphate ($K_2SO_4 \cdot ZnSO_4 \cdot 6H_2O$) were weighed into a micro beaker and dissolved in 1-1.5 cc. of water. The solution was acidified with 1-2 small drops of glacial acetic acid, heated for a minute on a boiling water-bath and the zinc then precipitated hot as quinaldinate by adding dropwise a solution of quinaldinate (1 Gm. of quinaldinic acid per 100 cc.) in excess of the theoretical requirement by 0.2-1 cc. The solution was again heated for a minute, the precipitate allowed to settle and collected on one side of the beaker. The supernatant liquid was then drawn off through an asbestos mat filter stick and the precipitate sucked as dry as possible. It was washed 5-6 times with 0.5-1 cc. of hot water. The beaker, with the precipitate and the filter-stick, was heated by placing it for 1-2 minutes on the boiling water-bath to remove all adhering water, then dried for 10 minutes in a current of air at 125° in a Benedetti-Pichler drying apparatus. The beaker, precipitate and filter stick were weighed in a microbalance after wiping with moist flannel and dry chamois according to prescribed methods. A table of results obtained by both the macro and micro methods is given.—P. R. RAY and M. K. BOSE *Mikrochem.*, 17 (1935), 11 (L. L. M.)

Ricinolein—Solubility of Distribution Coefficient, between Neutral Glycides and Water, of Substances Soluble in All Proportions in Two Solvents. The distribution coefficients of methyl alcohol, ethyl alcohol and acetic acid were determined for the system ricinolein and water and the average value for each found to be 0.23 at 20° .—A. LINDENBERG *Compt. rend. soc. biol.*, 118 (1935), 444, through *Squibb Abstract Bull.* 8 (1935), A-459 and A-477.

Sodium Cholate Preparations—Quantitative Determination of The method is based upon the fact that the bile acids yield cholic acid upon hydrolysis. The bile salts are separated from accompanying mucin and other proteins by extracting the bile salts with hot alcohol, filtering and evaporating the solvent. The bile salts (0.25 Gm.) are heated with 10 cc. of a 10% sodium hydroxide solution for two hours on a water-bath, then cooled, 30 cc. of water added, and 5 cc. of a 5% $BaCl_2$ solution to precipitate the fatty acids. The excess barium in the filtrate is precipitated with sodium sulphate, the solution warmed to enlarge the crystals of the fine precipitate and filtered through a thick filter. The filtrate acidified with sulphuric acid, is extracted with a peroxide free ether. The residue remaining after evaporation of the ethereal solution is dissolved in a few cc. of neutral alcohol and titrated with 0.1N alkali, using phenolphthalein as an indicator. The method can be used for any of the bile products or preparations.—G. VASTAGH *Pharm. Zentralh.*, 76 (1935), 189 (E. V. S.)

Spectroscopic Analysis A fifty page review with bibliography.—F. PAVELKA and H. MOLTERER *Mikrochem.*, 17 (1935), 47 (L. L. M.)

Spot Reactions—VIII Application of, to Detection of Organic Compounds. Tests described for dicarboxylic acids are based upon their conversion to dyes of the fluorescein series by means of concentrated sulphuric acid and resorcinol, tests for keto acids, upon conversion to fluorescent umbelliferone derivatives by means of the same reagents. Color and fluorescence are tabulated for the following compounds: oxalic, malonic, succinic, tartaric, tricarballic, maleic and citric acids, succinic anhydride, succinimide, normal potassium succinate, asparagine, trimellitic

acid trimethyl ester, naphthoic acid anhydride, saccharin and acetoacetic ester Full details of the micro-technique are given —F F V ANGER and O FREHDEN *Mikrochem*, 17 (1935) 29 (L L M)

Strophanthin g- and k- —Identification of, by Microchemical Test The identification of g and k-strophanthin is difficult The method is based on the micro determination of the melting point of the hydrazone or osazone of the monosaccharide split out on hydrolysis About 10 to 20 mg of strophanthin are treated in a narrow tube with 0.4 to 0.5 cc of 2% alcoholic hydrochloric acid The tube is sealed and heated for 10 hours on a water-bath The entire liquid is then transferred to a micro beaker and the alcohol carefully evaporated, the residue dissolved in 1 cc of water neutralized with sodium carbonate and then weakly acidified with 1 drop of acetic acid About 20 mg of medicinal charcoal is then added and the material allowed to stand for 5 minutes with stirring The charcoal is removed by filtration and the colorless filtrate evaporated in a micro beaker on a water-bath until only about 1 drop of liquid remains One to 2 drops of a freshly prepared solution containing 1 Gm phenylhydrazine hydrochloride and 1.5 Gm sodium acetate in 10 cc water is then added The walls of the beaker are rinsed with the liquid so as to bring all of the sugar into solution, the liquid then drawn up into a capillary tube sealed and heated on a water bath for 1 hour In order to obtain good crystals the tube is allowed to cool slowly in the water bath Examine the crystals under a microscope If they look impure or poorly formed, recrystallize them The tube is then opened at one end the crystals loosened by means of a glass thread, centrifuged and the supernatant liquid drawn off Some 30% alcohol is introduced, the tube sealed and heated in a bath until the crystals dissolve The solution is again allowed to cool slowly when well-defined crystals are obtained The crystals are blown onto a slide and then carefully washed between the slide and coverslip with 30% alcohol and then with water After drying in a warm current of air the micro melting point is determined Sufficient material is obtained for several melting point determinations In the case of g strophanthin, a melting point of 182–184° is observed which corresponds to rhamnosephenylosazone With k strophanthin, a melting point of 224° is obtained which corresponds to that of glucosazone —R FISCHER and W PAULUS *Scientia Pharm* 6 (1935) 32 (M F W D)

Tonicum—Determination of Arsenic in The author criticizes the method of van Giffen on the grounds of incomplete destruction of the organic matter affecting the bromine titration and the inaccuracy of the indicator used in the determination of arsenic in Tonicum He offers the following alternative method 5 cc of the 'Tonicum' is digested as suggested by van Giffen the heating being continued until the liquid remains clear for five minutes After cooling, 20 cc of water, 2 cc of N/10 permanganate and a small piece of pumice are added and the mixture boiled exactly five minutes over a low flame The excess permanganate is removed with a few drops of oxalic acid One cc of N potassium iodide and 12 cc of 25% hydrochloric acid are added to the cooled liquid After exactly 5 minutes it is titrated with N/100 sodium thiosulphate, 2 cc of starch solution being added near the end of the titration The last drops are added at one minute intervals with constant agitation A blank titration is subtracted from the result One cc of N/100 thiosulphate = 1.46 mg sodium methylarsenate (—7 mols of water of crystallization) The author claims results of less than 1% —J N VAN'T SPIJKER *Pharm Weekblad*, 72 (1937) 295 (E H W)

Tonicum N M P—Analysis of Tonicum N M P consists of a 125-cc package containing a liquid of the following composition Liquid extract of cola 200 cc, simple syrup 300 cc glycerin 340 cc, aromatic spirit 29 cc tincture cardamon 1 cc alcohol 45 cc, sodium methyl arsenate 1 Gm tincture nux vomica 10 cc, saccharated manganese 2 Gm, sodium bisphosphate 37 Gm water to make 1000 cc Sugar is determined by inverting 20 cc of the liquid with 12 cc of strong HCl in 68 cc of water by heating 10 minutes at 68–70° This is then cooled to 15–20°, transferred to a 500-cc flask together with 28 cc of 4N alkali and filled to the mark with water 5 cc of this is boiled with Fehling's solution and titrated by the method of Lehmann School The alcohol is determined by distilling 50 cc of the liquid diluted with 50 cc of water until the distillate measures exactly 50 cc the alcoholic content being determined by the specific gravity of the distillate Caffeine is determined by treating the distillation residue from the alcohol determination with 4 cc of 4N alkali in a separatory funnel, 50 cc of chloroform are added and the whole shaken for ten minutes This is followed by three successive shakings with 25 cc of chloroform the united chloroformic extracts being dried and weighed Glycerin is determined

by warming the aqueous liquid from the caffeine determination until the chloroform is removed, neutralizing with HCl and determining the glycerin by the method of *Ph Weekblad*, 71 (1934), 692. Phosphate is determined by taking up the ash from a sample in acidulated water, precipitating with magnesia mixture and finally igniting and weighing as magnesium pyrophosphate. Arsenic is determined by digesting 5 cc of the tonic, 5 cc of 30% hydrogen peroxide and 3 cc of H_2SO_4 in a Kjeldahl flask, adding 35 mg of hydrazine sulphate, boiling 10 minutes, adding 35 mg of KBr, cooling, adding 1 cc CCl_4 and two drops of saturated aqueous iodine solution and titrating with $N/100$ potassium bromate. 1 cc of $N/100$ potassium bromate is equivalent to 1.37–1.46 mg of methyl disodium arsenate, depending upon water of crystallization. Several tests for identity and purity are also given. Analysis of *Tonicum*, Roche is made in similar manner.—H J VAN GRIFFEN *Pharm Weekblad*, 72 (1935), 191 (E H W)

Tragacanth—Testing of. Rubrics of the Swedish Pharmacopœia, X, concerning tragacanth are reviewed. Statements regarding neutral reaction of the mucilage are incorrect. In his experience, Karsmark has never seen a neutral tragacanth mucilage. The requirement that a blue coloration shall be produced with $N/10$ iodine is seldom fulfilled by the best quality of tragacanth. Correct viscosity is more likely to go with failure to give the iodine color reaction (i.e., absence of starch grains). There is a relation of drug quality and viscosity of the mucilage, the higher the better. Also there is a parallel relationship between opalescence of the mucilage and viscosity.—K A KARSMARK *Farm Revy*, 34 (1935), 161, 169 (C S L)

Tung Oil—Iodine Value As a result of research on the quantitative relations of time, excess of Wijs reagent, and temperature to the iodine value of tung oil it was found that even after 12 days of contact the iodine value tends to increase. It is proportional to the excess of iodine in centigrams of equivalent iodine per Gm of oil, instead of being proportional to the percentage excess of Wijs solution, as usually stated. If the ratio of Wijs solution added and weight of sample of oil is kept constant almost identical iodine values are obtained when temperature and time are the same. When time of contact and excess of iodine are constant, the iodine value increases with increase in temperature. With the same excess of Wijs solution, almost identical iodine values can be obtained at different temperatures by varying time of contact. Standard conditions for converting iodine value are proposed.—K HO, C S WAN and S H WEN *Ind Eng Chem, Anal Ed*, 7 (1935), 96 (E G V)

Tyrosine—Separation of, from Cystine. A method for the separation of large amounts of tyrosine from cystine has been worked out which permits recovery of 92 to 94% cystine but which fails if very small amounts of cystine are mixed with very large amounts of tyrosine. The point of isolation of a mixture of cystine and large amounts of tyrosine is at a pH of 1.72 to 2.0.—F R GREENBAUM *Am J Pharm*, 107 (1935), 162 (R R F)

Umbelliferone—Content of, in Persian Gum Ammoniac. The Persian gum (*Dorema ammoniacum*) was shown to contain umbelliferone by the fluorescence developed upon alkalinizing a hydrochloric acid alcohol extract of the gum. The fluorescence may be seen in ordinary light, but is intensified in ultraviolet light. These positive findings disprove the literature statements that umbelliferone is not present in this variety.—K SZÄHLENDER *Arch Pharm*, 273 (1935), 234 (L L M)

Vegetable Oils—Absorption of Ultraviolet Light as Function of Commercial Treatment. Using Chevallier and Dubouloz spectrophotometric method (*Bull Soc Chim Biol*, 14 (1932), 1076–1087) on 1% solutions of olive oil in hexane it was found that virgin or "extra" olive oils have an absorption coefficient ($\log I/I_0$, in which I and I_0 are the intensities for the solution and the solvent, respectively) at 2700 Å of less than 0.200, higher values indicate either a refined oil or a mixture of refined and virgin oils.—J GUILLOT *Ann Fals*, 28 (1935), 69–75 (A P-C)

Vitamin A—Determination of, in Oils by the Spectrophotometric Method. While all authors are in accord regarding the selective absorption of vitamin A at 3280 Å, they do not agree as to the method of utilizing this property for the assay of vitamin A in oils. In previous papers Chevallier, *et al* have shown the parallelism that exists between the value of absorption and the biological activity of a product. In the present paper they again show that when working with oils with an absorption maximum at 3280 Å the physical measure corresponds to the biological titer. For highly active fish liver oils in 1% hexane solution in 1-cm cell, an intensity of absorption of 3280 Å = 1 for $\log 1^\circ/1$ was equivalent to 730–750 U S P vitamin A units. For an ordinary common cod liver oil manufactured and preserved under the best conditions, the inten-

sity of absorption of $3280 \text{ \AA} = 2.7$ for $\log 1^\circ/1$ (1° solution) was equivalent to 2025 U S P units of vitamin A. Examination of a large number of common cod liver oils showed a vitamin A activity varying from 150 to 3000 units. Badly prepared or preserved oils show an absorption spectrum displaced toward the shorter wave-lengths due to the decomposition products of vitamin A. In this case it is not possible to utilize the spectrophotometric method. Several advantages of this method are discussed.—A. CHEVALLIER and P. CHABRE. *Bull. soc. chim. biol.*, 16 (1934), 1451, through *Squibb Abstract Bull.*, 8 (1935), A-485.

Vitamin A—Differential Reactions between Carotene and Oils Rich in Antimony tri chloride, trichloroacetic acid and chloral hydrate each yield with carotene and with halibut liver oil a characteristic blue color. The blue color persists when the reaction mixture containing carotene is heated to 100° , whereas the halibut liver oil mixture changes to purple. Cod liver oil and butter fat yield with trichloroacetic acid and chloral hydrate immediately a purple without heating. A reagent containing sulphuric acid and formaldehyde forms with carotene a purple zone, with halibut liver oil a bright red color is developed in the acid layer and a blue to purple in the chloroform layer. The reagents may also be used to differentiate carotene and vitamin A from ergosterol and cholesterol.—VICTOR E. LEVINE and GEORGE E. BIEN. *Proc. Soc. Exptl. Biol. Med.* 32 (1935), 873 (A. E. M.)

Vitamin A—Differentiation of, from Carotene by Means of Antimony Trichloride Vitamin A and carotene develop a blue color when treated with antimony trichloride in chloroform solution. The color produced by carotene persists after heating to 60° whereas that caused by vitamin A changes into red or violet-red. Pyrocatechin which was used by some authors for differentiation, is not only needless, but actually inhibits the development of the blue color.—A. C. ANDERSEN and V. E. LEVINE. *Proc. Soc. Exptl. Biol. Med.* 32 (1935), 737 (A. E. M.)

White Mineral Oil and Petrolatum—Use of, in Pharmaceutical and Cosmetic Practice There is very little in the literature about chemical and physical characteristics of these products. Many topics are considered in the present paper. Theory of the origin of crude oil, its occurrence in Asia, Europe and North America, the classification into three general types according to chemical structure—naphthene base crude, paraffin base crude and mixed base crude—and where they are found. The present process for white oil refining was invented by J. Markovnikov, a Russian chemist, about 1887, and in 1895 another Russian, Grigori Tetroff, perfected it so that it was commercially useful. The principle of refining processes involves removal of the light fractions and then fractionating the residue, the main object being removal of unsaturated hydrocarbons. These hydrocarbons are unstable, give unrefined oil its odor and taste. The oil is treated with sulphuric acid, washed with alkalis and filtered. Removal of unsaturated hydrocarbons or other impurities is necessary if oil is to be used internally or even for cosmetics, because of possible skin irritation. The U S P test for unsaturates is done with sulphuric acid and is satisfactory except for the vague specification of "pale amber." U S P XI has adopted a definite color standard. The U S P has definite specifications for viscosity and for internal use the viscosity should be high, since it is believed that property lowers tendency to leakage. Cloud point is important because it indicates absence of solid paraffins but opalescence might be due to moisture. Moisture is readily absorbed. The British Phar. directs that the oil be dried by heating to 110°C and cooling in a desiccator before determining cloud point. Specific gravity has significance. Action on intestinal tract is not simple lubrication but the oil emulsifies with intestinal contents so the higher the specific gravity, the more readily it will emulsify. The U S P lead oxide test for sulphur or sulphur compounds no doubt gives negative results with all oils offered for medicinal purposes. Sources of crudes for white mineral oils are discussed. Uses of the refined oils are emulsions with various gums, nasal sprays, baby oils, ointments and creams. Essential requirements for cosmetic white oils are correct viscosity and preference is for those of naphthene base type. Oils of low viscosity are generally employed for liquid brillianines along with a mineral oil which is volatile like a completely refined kerosene. Mineral oils are used in the so-called sun tan oils, in vanishing creams to prevent drying out, as softening agents in brushless shaving creams and other softening preparations. Petrolatum is closely related to mineral oil and to paraffin but with important differences. Petrolatum may be considered a colloidal system in which the solid wax is the external phase and the oil the internal phase. The liquid would separate from the solid but for the presence of a gel former called proto-substance. Proto substance is present in satisfactory quantities in natural petrolatum but is often removed in refining.

Petrolatum is obtained only from paraffin base and mixed base crudes. Purification by "adsorption," contact with porous material like bone black, etc., is slow and tedious. More rapid methods with strong chemicals sacrifice quality for very light color. Petrolatum used for pharmaceutical and cosmetic preparations should be of medium fibre. Long fibre makes sticky or stringy product, short fibres give too thin a body. Melting point need only be high enough to preclude liquefying of the product in summer. Consistency is important and can be determined by an instrument similar to the asphalt penetrometer. U S P petrolatum can be classified into three distinct types: (1) medium melting point and medium consistency, (2) low melting point and soft consistency, (3) high melting point and medium consistency. Those of type No 1 are the standard ones of commerce, suited for pharmaceutical and cosmetic purposes. Type No 2 is recommended for resale as petroleum jelly for household use. Type No 3 is used only where addition of liquids would reduce melting point too much. A fourth type which has high melting point and hard consistency is useful in lip and paste rouges. Selection of correct type of petrolatum should depend upon the purpose. The U S P is recognizing progress in refining of petrolatum by proposed changes in official ointment formulas.—ERICH MEYER *J Am Pharm Assoc*, 24 (1935), 319 (Z M C)

TOXICOLOGICAL CHEMISTRY

Apiol—Detection and Determination of, in Viscera Treat a suitable sample of viscera by the Stas Otto method for poisons, apiol, if present, may be contained in the petroleic ether or in the acid ether extract. Partially evaporate the solvent, add sufficient decinormal silver nitrate (10 cc) to precipitate any oxalates that may be present. Let stand 10 minutes, filter, precipitate the excess silver with concentrated hydrochloric acid (avoiding an excess), filter into a round bottom evaporating dish, evaporate slowly on the water bath, add two 2 cc portions of 1 + 1 nitric acid, evaporate 3 times (with intermediate addition of a few cc of water), dissolve the residue in 10 cc of hot water, filter, wash, neutralize with 3 drops of ammonia water, add 1 cc acetic acid, heat, add calcium chloride solution to complete precipitation, let stand 3 hours on the water-bath, filter, wash, dissolve the precipitate in 5 cc of boiling 1 + 9 hydrochloric acid, add 5 cc of 1 + 4 sulphuric acid and titrate hot with decinormal potassium permanganate. The equivalence between the permanganate and apiol should be determined experimentally, as the oxidation with nitric acid does not give 1 molecule of oxalic acid per molecule of apiol.—I PAYEN *Ann Méd Légale Criminel Police Sci*, 15 (1935), 59-61 (A P-C)

Lead Poisoning—Detection of With the introduction of the Feigl "Tupfelreaktion" reagents, the micro detection and in many instances the quantitative estimation of many elements has been made possible. One of the best known and most useful of the spot-test procedures is the dithizone method for detecting lead. This has been applied to biological material by J R Ross and C C Lucas (*Canad Med Assoc J*, 29 (1933), 649) and W Lineweh (*Deut Arch klin Med*, 175 (1933), 157). Their method takes advantage of the fact that a cherry red color is produced in the lower layer when a lead containing fluid is shaken with a carbon tetrachloride or chloroform solution of dithizone. By the use of this dye (diphenyl-thiocarbazonc) as little as 0.1 γ of lead can be detected. Such sensitivity brings the chemical method into the range claimed for the spectrograph, and it is so much easier to apply that it is likely to gain, and for the present to retain, the favor of biochemists concerned with lead estimations.—Lancet, 228 (1935), 501 (W H H)

Organic Solvents—Modern A brief discussion of the difficulties inherent to the identification of organic solvents from the standpoint of toxicology and medico legal work.—H ZANGGER *Ann Méd Légale Criminel Police Sci*, 15 (1935), 13-20 (A P-C)

Trichloroethylene—Intoxication by A detailed description of a fatal case of intoxication by trichloroethylene of a workman who had painted a tank with a paint consisting of asphalt dissolved in trichloroethylene. A 20 Gm portion of the tissues of the corpse was distilled with 60 cc of alcohol and 5 cc of 5% alcoholic solution of tartaric acid, and the distillate was refluxed for 1 hour with a 10% alcoholic caustic potash solution free from chlorides, the solution gave a decidedly positive test for chlorides, but no quantitative determination was made.—C VALLEE and J LECLERCQ *Ann Méd Légale Criminel Police Sci*, 15 (1935), 10-12 (A P-C)

PHARMACOGNOSY

VEGETABLE DRUGS

Drugs and Bugs In general, drugs with abundance of starch, inulin and sugars are most liable to attack of pests. Some knowledge of harmful insects, their life cycle and habits and some of the means of preventing and combating their ravages is essential. Adult insects have well developed mouth parts and can be classified into two groups: mouth parts fitted for chewing, mouth parts fitted for sucking. Pharmacists are chiefly interested in the biting ones though the sucking ones cannot be entirely ignored because some young biting ones later develop into sucking insects. The drug store beetle and the square-necked grain beetle are described and drugs which they infest are listed. Control is by fumigating or by heating to 49° C. Carbon disulphide is recommended. The author makes suggestions for detecting them, evidences of and classification of, preventive measures including sanitation, temperature and moisture means of extermination, heat for eggs, larvæ and insects and fumigation with carbon tetrachloride or chloroform. Ideal pest exterminators must arrest growth or destroy parasite, be more toxic to pest than host, be adherent and maintain active properties for a period of time, enter into intimate contact with parasites or their elements. To prevent vegetable or mold parasites drugs should be kept in dry state. The list of drugs given may be kept satisfactorily by the so called "vacuum method". New supplies are placed in a vacuum chamber for several hours then transferred to air tight containers.—ERNST T. STUHR *J Am Pharm Assoc*, 24 (1935), 285 (Z M C)

Leonurus Cardiaca The herb, whole and powdered, is described botanically, macro and microscopically. Chemically analysis shows volatile matter at 100° C 6.92%, total ash 13.64%, petroleum ether extractive, 1.82%, ether extractive, 4.88%, alcohol extractive, 21%, water extractive, 29.90%, volatile oil 0.05%, and crude fibre, 15.11%. A 2% aqueous acid extract is precipitated by lead acetate; the filtrate is precipitated by basic lead acetate, weakly reduces Fehling's solution, and gives precipitates with the usual alkaloidal reagents. Microsublimation yields a product which reacts slightly with Mayer's or silicotungstic acid reagents. The percentage of alkaloid present (0.05%) is determined by the usual method of extraction using an ammoniacal ether mixture as the initial solvent. The tannin content is tabulated and is determined in the samples by the hide powder method of precipitation and by the method of Schultze. Therapeutically, various workers state its use as a tea for prostate sufferers, climacteric complaints as an expectorant, astringent, sedative and for its heart action. Pharmacologically, no such actions were obtained on either the dog, rat, mouse or frog. The astringent action is due to the tannin present. The direct color and the color under the fluorescence lamp of extracts prepared using various solvents is tabulated.—W. PEYER and H. VOLLMER *Pharm Zentralh*, 76 (1935), 97 (C V S)

PHARMACY

GALENICAL

Cocoa Butter—Use of, as Excipient in Pills Containing Extracts Pills containing vegetable extracts can be made as well with cocoa butter alone as with a mixture of this with chocolate. Preparation is described of pills of *Sagralm* (*Pillulæ Frangulæ Compositæ* Ph. Dan., 1933) and of *valerian* pills under various conditions of mixing and with cocoa butter only. Use of both licorice root powder and yeast powder as excipients is recommended. The disintegration rates of the two sorts of pills are studied by a method of determination of disintegration time which is described. The errors of dosage of hand made pills are considered. If the pills were carefully made these errors were found to be under 2% and due chiefly to the weight variations of the pills. The mean deviation from the mean weight of 1800 pills weighed singly to an accuracy of 1 mg. was 2.36%. The pills were also weighed in groups of 100 and the mean percentage deviation from the mean weight so obtained was found to agree well with that observed for the entire group of 1800.—A. T. DALSGAARD *Dansk Tids Farm* 9 (1935) 73 97 (C S I)

Homogenizer—Hand Type, and Its Use in Making Emulsions A small inexpensive instrument has lately appeared on the market and it has been found very convenient and efficient for manufacturing pharmaceutical emulsions on a small scale. The author's conclusions are: (1) The efficiency, versatility and ease of operation of this apparatus are outstanding. (2) It pro-

vides a saving of materials both in the elimination of waste through cracked emulsions and the reduction in the necessary amount of emulsifying agent (3) An emulsion prepared by its use possesses a high degree of dispersion and a much slower rate of creaming than emulsions prepared by the usual trituration methods—LINWOOD F TICE *Am J Pharm*, 107 (1935), 158

(R R F)

Tolu Coating, U S P X and N F V—Value of A study was made of tolu coated pills to determine percentage of disintegration in the body Pills containing methylene blue and barium sulphate were made The barium sulphate was used so that the X-ray could be used to locate the position of the pills in the digestive tract and the methylene blue by its property of coloring the urine made possible the determination of disintegration where X ray was not used and in determining entirety of coat Coated pills were placed in water to see if the coating was perfect, leakage of methylene blue showing any opening Microscopic examination indicated that the coating was about 0.1 mm thick, no thicker than necessary to protect the pill Tiny depressions did not take as heavy a coat as smoother surfaces The authors believe that if the coating were absolutely uniform the pills would be as impervious to water or digestive fluids as lead shot Old tolu was better than fresher because it had lost most of its volatile oil and there was greater disintegration of pills coated with it Four different samples were used and all coatings were tested in two ways Color of urine was observed for sixty hours When the X-ray was used, the subject was given six pills Radiographs were taken at intervals, a small teaspoonful of Bari o-meal being given before the first Each series of tests is reported in considerable detail, number of subjects, disintegration time, etc Altogether 286 pills were given 112 subjects were used, 102 pills disintegrated The percentage of disintegration was 35.66 most of it taking place in the colon, probably too late for proper absorption It is recommended that gelatin coating be substituted for tolu coating in the forthcoming revisions of the Pharmacopœia—F S BUKEY and MARJORIE BREW *J Am Pharm Assoc*, 24 (1935), 291

(Z M C)

PHARMACOPŒIAS AND FORMULARIES

British Pharmacopœia—Revision Notes on The article consists of a critical review of the following products of the British Pharmacopœia Acidum Hydrocyanicum Dilutum, Amylum, Carboni Dioxidum, Eucalyptol, Liquor Ammoniae Fortis, Liquor Hydrogeni Peroxidi, Liquor Plumbi Subacetatis Fortis, Oleum Eucalypti, Glycyrrhiza, Quassia, and Prunus Serotina—J HENDRY and P A BERRY *Australasian J Pharm* 16 (1935), 37

(T G W)

Swiss Pharmacopœia—Practical Questions on It was decided at the convention at Baden to publish the work of the Zürcher Commission on Pharmacopœial Questions in the *Schweiz Apoth Ztg* Information is given about 57 articles official in the Swiss Phar stating, in some cases, changes which will be made in the new edition of the same There follows a description of specialties, endorsed by the Schweiz Apoth-Verein which have been taken into the new pharmacopœia Because of the numerous changes in the new pharmacopœia, the commission recommends that all formulæ and prescriptions specify whether the ingredients should be those of the 4th or the 5th edition Reference is made to a table in the new edition which shows the differences in the preparations The Pharm Helv V becomes official May 1, 1936—*Schweiz Apoth Ztg*, 73 (1935), 165

(M F W D)

NON OFFICIAL FORMULÆ

Manicure Preparations—Modern The article consists of a number of formulas for manicure preparations which could be made by the pharmacist The formulas listed consist of cuticle removers, nail bleaches nail polishes, nail white and cuticle cream—*Chem and Drug*, 122 (1935), 357

(T G W)

Nail Polishes and Enamels The preparation of nail polishes is carried out in the sifting and mixing machines The different ingredients are weighed out in their respective proportions and simply thoroughly mixed and sifted Ordinary putty powder, or oxide of tin is the principal constituent To this are added the usual powder materials—chalks, pumice powder kaolin osmo kaolin and zinc oxide The tinting of the mass is done by adding a small proportion of selected dye Eosine Bengal red and various organic dye materials are used The coloring matter is added to one constituent, and the latter is then incorporated with the others When liquid polishes are used purely chemical preparations have been substituted The more cus

tomary practice is to suspend the ordinary polishing powder in selected gums and glycerine. The suspension must be perfect, and permit of the liquid being filtered so that the product for the market is represented by a comparatively clear solution. Tragacanth, starch and similar agents are used. **Nail Enamels**—A well-made enamel confers a bright, lustrous and yet natural appearance. Solvents and plasticizers represent the principal components. Nitro cellulose is used to produce the best enamels. The enamels at present on the market are chiefly those of nitro cellulose, celluloid, and benzoin. The preparation used by photographers which consists of celluloid obtained from scrap sources and dissolved in amyl acetate is widely employed. It consists of cutting up the scrap and charging into a comparatively large mixing pan. Amyl acetate and acetone are poured into the pan, and heat gently applied. The consistency of the product can be varied by the amount of scrap added and it should be reduced to a syrupy condition. Some selected perfume is then added in the usual manner, and the charge emptied. Larger manufacturing perfumers employ ester gum and other addition agents to improve the lustre. Selected benzoates, glycols, oxalates, tartrates and camphor are used as plasticizers. The plasticizer used should, where possible, possess a comparatively high boiling point whereby the solvents of the cellulose are thus given the opportunity to evaporate, and leave the enamel in the desired condition. The plant used for systematic production consists of a small specially constructed boiler, in which the ingredients are added. Air is excluded, and the temperature raised by steam heat with the greatest accuracy. When all material has passed into solution the odor of the product is noted. Some of the organic solvents such as the acetones and acetates possess a strong odor, and it would take much perfume to overcome it. Methods such as those employed by deodorizers of oils consist of passing air or even coal gas through the mass, but criticism arose over the possibility of unexpected and uncontrolled reactions occurring. For this reason the work was modified to simply mixing the solvent and plasticizer raising to the desired temperature cooling and adding the selected perfume. It is a good plan to allow the preparation to rest for some time in the air tight vessel before adding the perfume. The final additions are the perfume and the dye.—A. G. AR. **END Perf and Ess Oil Rec** 26 (1935) 122 (A C DrD)

Violet Perfumes A discussion of violet perfumes dealing with the cultivation of the flower, odor, violet leaf, the use of ionone, blenders, aging and soap perfumery is given.—H. SILMAN. **Perf and Ess Oil Rec**, 26 (1935), 119 (A C DrD)

Cherry Gum—Emulsifying and Coating Properties of The author states that cherry gum is slightly soluble in water, most of it swells in water without going into solution. Because of this property of cherry gum, a proper emulsion cannot be obtained. Under these circumstances cherry gum cannot be used as a suitable substitute for gum arabic in the preparation of emulsions.—N. P. KALASCHNIKOW. *Soyuz Pharmaz*, 5 Nr 4 (1934), 35-35. *Pharmakol Aht Leningrad wiss prakt Pharmaz inst*, through *Chem Zentr* 106 (1935), 925 (G B)

Galenic Preparations—Investigation on III Fowler's Solution This preparation has undergone numerous changes in formula and preparation since its introduction in 1786. The Swiss Phar. V directs a solution to be made of 1 part arsenous acid and 1 part potassium bicarbonate in 2 parts water then dilute with 50 parts water and neutralize to litmus paper by the addition of about 9.5 cc. N hydrochloric acid, after which the preparation is completed. This amount of hydrochloric acid is just equivalent to the potassium bicarbonate. Since arsenous acid does not redden blue litmus, it plays no role in the neutralization. It may be concluded that the preparation so made contains no potassium arsenite and is a solution of arsenous acid and potassium chloride. Considering this fact the title of the preparation is false. If instead of 1.0 Gm arsenous acid 1.476 Gm potassium metaarsenite ($KAsO_3$) is used and the solution neutralized to litmus with hydrochloric acid the resulting solution is exactly identical with that of the Swiss Phar. and is most rapidly and easily prepared. A correct title for the preparation would be 'Sol. Acidi arsenicosi cum Kalio chlorato'.—L. ROSENTHALER. *Scientia Pharm*, 6 (1935) 41 (M T W D)

Glycenum Thymolis Ruhrum, A. P. F.—Notes on Coloring of The coloring material used in this preparation have not been satisfactory. The preparation formerly contained 20 minims each of Solution of Carmine and Tincture of Cudbear, and in 1934, 40 minims of each were directed in order to delay a noticeable fading of the color. The author attempted to determine which of the two coloring agents was at fault and to find an alternative coloring matter which would prove more permanent. Solution of Carmine was found to be more stable than the Tinc-

ture of Cudbear, and is moderately satisfactory if the preparation is stored in a dark place. Amaranth 184, in the form of Liquor Ruber, A P F, 80 minims in 20 fluidounces, forms a satisfactory coloring agent and can be stored under ordinary light conditions without decomposition — E E NYE *Australasian J Pharm*, 16 (1935), 41 (T G W)

PHARMACEUTICAL HISTORY

Revolutionary Account Book of Christopher, Jr, and Charles Marshall The Marshall Drug Store, a prominent colonial pharmacy, was founded in 1729 by Christopher Marshall, Sr, a "fighting Quaker" The sons succeeded to the business and Charles, apothecary, botanist and chemist, attained a fine reputation for integrity and skill In his old age he became the first president of the Philadelphia College of Pharmacy In the archives of the College is the book described in the article It is a typical "Day Book" of 32 leaves The upper part of the cover is shown and several facsimile pages Entries show miscellaneous character of the business Though major business was in drugs and medicines there was extensive trade in paints, oils and glass Prices are in pounds, shillings, pence Spelling is poor Dr Abraham Choivet's name appears frequently as does Dr John Morgan's, Christopher Sower, a Germantown printer who published the first Bible in America was a customer Some interesting items are discussed as well as prices of substances that are still in use — CHARLES H LA WALL and MILLICENT R LA WALL *J Am Pharm Assoc*, 24 (1935), 302 (Z M C)

PHARMACEUTICAL EDUCATION

Botany Course—Value of, as a Foundation for the Pharmacognosy of Stem and Bark Drugs It is necessary to distinguish between aerial stems and underground stems The following features need emphasis Location of growing point, manner of branching, origin of branches buds and leaf scars, functions of each internal or microscopic structure of each The outstanding characteristics of the four types of underground stems rhizomes, corms, bulbs and tubers should be pointed out Leaf scars and bud scales on upper surface of rhizomes should be pointed out For bulbs, onion or garlic or squill may be used Outer papery membrane, fleshy scale enclosing buds and roots should be emphasized The corm does not consist of thick fleshy scales but is solid and more flattened from top to bottom The Irish potato is an excellent example of a tuber Buds should be examined, as well as outer corky layer and rows of vascular bundles internally Microscopic structure is more important than gross anatomy A knowledge of tissues present in entire stem enables the student to understand functions Structure, too, can be used to distinguish between types of stems, monocot, dicot and fern Comparisons should be thorough in order that the student will comprehend meaning of all the terms encountered in the official description of the structure of drugs derived from the stem of a plant Types of vascular bundles need detailed study The change in vascular bundles taking place in stems which undergo secondary growth can be shown with *Menispermum Canadense*, *Cascara Sagrada* in transverse section is excellent for detailed study of a bark — C C ALBERS *J Am Pharm Assoc* 24 (1935), 310 (Z M C)

Chemistry—How Should Fundamental Courses in, Be Taught in a College of Pharmacy How these courses are presented and the training of the individuals who present them are of paramount importance Important applications of organic chemistry should be stressed somewhere in the pharmacy course but the three hours a week of classroom work devoted to organic chemistry is hardly enough for adequate foundation for specialized courses Practical application would diversify but would result in weakness rather than strength Interrelationships must be established in order to coordinate organic and inorganic courses If principles of hydrolysis are taught, they only need to be reviewed when studying solution of aluminum subacetate of the National Formulary Also in the preparation of syrup of calcium iodide, iron is oxidized to its higher valence before precipitation with calcium carbonate because study of solubility products of ferrous carbonate and ferric hydroxide show that the syrup will contain less iron if removed after oxidation Evolution of carbon dioxide may be pointed to as evidence of hydrolysis of ferric carbonate and a reason why the precipitation takes place as rapidly and completely as it does in spite of the little difference in solubility products of calcium carbonate and ferric hydroxide There is fundamental chemistry in the preparation of this syrup but it is not essential that it be mentioned when hydrolysis, oxidation and solubility products are discussed in general chemistry It seems more

essential that teachers of professional and technical courses have a profound knowledge of fundamentals upon which their specialties rest than that teachers of fundamental subjects have in mind all the important and useful applications of their subject. Good teaching requires that a course be interesting so judicious use of applications is permissible but this does not change the general principle — ERNEST LITTLE *J Am Pharm Assoc*, 24 (1935) 307 (Z M C)

Homeopathic Pharmacy—Basic Demands of The author stresses the need of physiological and pharmacological studies and assays for homeopathic medicines — H NEUGEBAUER *Pharm Zentralh*, 76 (1935), 192 (E V S)

Homeopathy Homeopathic practice seems to be rather widely developed in Germany. In the *Süddeutsche Apoth-Ztg* (Feb 22, 1935) is the report that 400 pharmacists of southern Germany took a course in homeopathy given by E Bamann. The general outline of the course and its divisions such as "Development of Homeopathy," "Technique of Preparing Dilutions," etc., are described and briefly commented upon — E K *Schweiz Apoth Ztg*, 73 (1935), 172 (M F W D)

Teachers and State Board Examiners—Problems of the Scope of practical pharmacy and dispensing has become more complicated because of the limited amount of practical drug store experience that candidates for registration have and because of the large number of new preparations put on the market for all to learn about. It is necessary for teachers to supply training that once was obtained in drug stores. Teaching processes and procedures of the U S P and N F is not a burden but with hundreds of others and combinations of them added it seems possible to teach no more than basic principles underlying the art of compounding and dispensing. Examiners are confronted with difficult problems like the number and type of prescriptions to be given to an applicant, the number of times an applicant may fill a prescription and how it should be graded. If examiners and teachers were to cooperate, plans might be made for more uniform examinations. Since comprehensive examinations are best the larger the number of preparations the better. It is suggested that 60% consist of U S P and N F preparations with directions given and the remaining 40% prescriptions without directions. Reading original prescriptions is seldom considered but it might be made a part of the test to determine whether the candidate can handle the prescription from the time he receives it until it is turned over to the customer — HARRY W MANTZ *J Am Pharm Assoc*, 24 (1935), 296 (7 M C)

MISCELLANEOUS

Homeopathic Pharmacy in 1934 A review of the work accomplished in homeopathic pharmacy in 1934 — H NEUGEBAUER *Pharm Zentralh*, 76 (1935), 212 (E V S)

Profit—The Way Out of the Depression To protect the public, prices must be at a level that allows adequate pharmaceutical service. A code of fair competition must be a guide for ninety per cent of the stores. Laws of the States demand that highly skilled persons sell drugs and if there is only one employee that one must be a registered pharmacist. In small retail stores minimum code wage is not apt to be maximum drug store wage. All fair trade provisions will control selling power of all items controlled by the code. The public must pay the cost of handling all items. This fundamental importance is shown by specific figures. If recovery is to come to 90 per cent of the retailers under the National Industrial Recovery Administration, sales must represent cost of merchandise overhead and net profit. If sales do not pay cost of merchandise and overhead, bankruptcy will result and lack of adequate drug service will become a consumers' problem. A sale without profit is without honor under any code. Without profitable sale there is no means to pay employee no purchasing power — W BRUCE PHILIP *J Am Pharm Assoc* 24 (1935) 298 (7 M C)

PHARMACOLOGY TOXICOLOGY AND THERAPEUTICS

PHARMACOLOGY

Bile Salts—Influence of, on the Nervous System Following Intraspinal Usage Sodium desoxycholate can be introduced in minute doses intraspinally in cats without injury to the cord. Larger doses produce motor and sensory disturbances and death from respiratory paralysis. Traumatized spinal tissue is highly susceptible to even minute doses of bile salts in alcoholic solution though resistant to the same dose in aqueous solution. Spinal fluid protein and cord tissue

reduce the hemolytic action of bile salts—S S LICHTMAN and E L STERN *Proc Soc Exptl Biol Med*, 32 (1935), 1201 (A E M)

Calcium Compounds—Comparative Study of the Absorbability of Reference is made to two preliminary reports which were concerned with dicalcium phosphate, calcium chloride, lactate, glycerophosphate, gluconate, hexacalcium inositol hexaphosphate and calcium lacto phosphogluconate. The present paper deals with the first six. The literature was reviewed in previous reports. The technique is based on the antagonism between magnesium and calcium earlier experiments having shown that animals narcotized by magnesium are awakened by injections of calcium salts, and conversely, animals which have absorbed increasing quantities of calcium require greater amounts of magnesium for narcosis. Details of procedure are given and results are tabulated. Arranged according to maximum amount absorbed they appear in following order: lactate, gluconate, chloride, hexacalcium inositol hexaphosphate and dicalcium phosphate (the same) and lastly calcium glycerophosphate. There is a constant rise until the fourth hour when the maximum is reached for all except the chloride which requires five hours. That calcium lactate heads the list agrees with the findings of McGowan and Berghem. The lactic acid radical has a significant influence, Rowe and Kahn have shown that alkaline secretions have an inhibitory influence on the rate of calcium absorption. The authors believe it is reasonable to assume that calcium lactate may be the best calcium compound for oral administration in human subjects as it was in the albino mice used as test animals in these investigations.—A RICHARD BLISS JR, and ROBERT W MORRISON *J Am Pharm Assoc* 24 (1935), 280 (Z M C)

Candicine—Contributions to Pharmacology of Intraperitoneal injection of 6 mg of candicine iodide/100 Gm in adult white rats, produced death from respiratory paralysis, 5 mg / 100 Gm killed 60% of the rats. The rats showed muscular incoordination, trembling and sometimes violent convulsions. In dogs, an intravenous dose of 2-6 mg /Kg suppressed the cardio-regulator effect of the vagus, 6 mg /Kg suppressed the effect of the sciatic nerve, 4-6 mg /Kg suppressed the vascular effect of nicotine and the pressor but not the hypotensor or muscarine effect of tetramethylammonium iodide. In sympathetomized dogs candicine produced a lesser hypertension than in normal dogs due in part to a discharge of adrenaline and in part to a peripheral vascular effect since it persisted, though somewhat diminished, after suprarenalectomy.—F P LUDWEN *Compt rend soc biol*, 118 (1935), 593, through *Squibb Abstract Bull*, 8 (1935), A-499

Carbon Tetrachloride—Experimental Investigation on Its Toxic Action by Repeated Inhalation. Exposition of a few minutes in an atmosphere containing carbon tetrachloride is sufficient to produce subacute inflammatory lesions of the liver and kidneys provided exposition is repeated and that the atmosphere is sufficiently rich in carbon tetrachloride. The hepatic lesions seem to be more important than the renal which is characteristic of carbon tetrachloride irrespective of its mode of administration. The lesions are in all respects comparable with those observed following upon the introduction into the organism of small doses of toxic substances. The hepatic lesions, in particular, are constituted by a reactional process of periportal fibrosis, it is a parenchymatous disturbance that is entirely different from that observed in the case of massive intoxication through the digestive tract.—P LANDE and P DERVILLE *Ann Med Legale Criminol Police Sci*, 15 (1935), 25-27 (A P C)

Daphnia—Propagation of, for Experimental Use. The propagation of *Daphnia Magna* for laboratory experiments is assured by extremely simple methods merely adding certain animal or plant products commonly available, without special preparation, to water (tap or distilled) suitable for drinking purposes (practically free of chlorine and heavy metals) alkalinized with an excess of calcium carbonate (coarsely crushed marble stone) or precipitated chalk, preferably aerated and kept at room temperature (21° C) in the diffuse light of northern exposure. The cultivation of consecutive generations of suitable experimental animals (females developing parthenogenetically summer eggs) may be assured with any of the common natural manures of animal excretions, provided (1) the amounts given at one time are not excessive as otherwise putrefaction may occur (2) the applications are frequent enough to prevent starvation (3) the accumulation of toxic substances is prevented through fairly frequent (monthly or bi-monthly) renewal of cultures and artificial aeration if necessary (4) a sufficient number of vigorous animals is used to start the daphnia culture. The following food substances were found satisfactory. Dried shredded sheep manure and dried shredded cow manure, dried and malted milk and dried pig

essential that teachers of professional and technical courses have a profound knowledge of fundamentals upon which their specialties rest than that teachers of fundamental subjects have in mind all the important and useful applications of their subject. Carbon Tetrachloride—Experimental Investigation on Its Toxic Action by Repeated Inhalation Exposition of a few minutes in an atmosphere containing carbon tetrachloride is sufficient to produce subacute inflammatory lesions of the liver and kidneys provided exposition is repeated and that the atmosphere is sufficiently rich in carbon tetrachloride. The hepatic lesions seem to be more important than the renal which is characteristic of carbon tetrachloride irrespective of its mode of administration. The lesions are in all respects comparable with those observed following upon the introduction into the organism of small doses of toxic substances. The hepatic lesions in particular, are constituted by a reactional process of periportal fibrosis, it is a parenchymatous disturbance that is entirely different from that observed in the case of massive intoxication through the digestive tract.—P LANDE and P DERVILLE *Ann Med Legale Criminol Police Sci* 15 (1935), 25-27 (A P-C)

Daphnia—Propagation of, for Experimental Use The propagation of *Daphnia Magna* for laboratory experiments is assured by extremely simple methods, merely adding certain animal or plant products commonly available, without special preparation to water (tap or distilled), suitable for drinking purposes (practically free of chlorine and heavy metals), alkalized with an excess of calcium carbonate (coarsely crushed marble stone), or precipitated chalk preferably aerated and kept at room temperature (21° C) in the diffuse light of northern exposure. The cultivation of consecutive generations of suitable experimental animals (females developing parthenogenetically summer eggs) may be assured with any of the common natural manures of animal excretions provided (1) the amounts given at one time are not excessive as otherwise putrefaction may occur (2) the applications are frequent enough to prevent starvation (3) the accumulation of toxic substances is prevented through fairly frequent (monthly or bi monthly) renewal of cultures and artificial aeration if necessary (4) a sufficient number of vigorous animals is used to start the daphnia culture. The following food substances were found satisfactory. Dried, shredded sheep manure and dried shredded cow manure dried and malted milk and dried pig

blood Plant products such as cotton seed meal and soy bean flour were also found satisfactory, both particularly advantageous with the addition of 0.003% urea. Certain micro organisms such as infusoria, algæ, bacteria and yeast also prove of value. The host of enemies which may destroy daphnia can be rather readily kept out of cultures or, if found present, usually quickly removed. Careful attention to the details of propagation which are given at great length assures unequalled uniformity in age, size and vitality of the daphnia. Over 1000 may be obtained in one month starting with six animals.—*Am J Pharm*, 107 (1935), 103 (R R F)

Digitalis—Studies on the Bioassay of II New Leg-Vein and Intramuscular Guinea Pig Methods Investigation of the value of the guinea pig in the assay of digitalis has had further study. New leg-vein and intramuscular minimum lethal dose methods with simplified technique have been devised and checked against older methods. Relative occurrence of cardiac and respiratory failure was investigated because of the question of primary cause of death. Detailed methods are given. Experimental procedure is described, and a typical protocol of the course of events in the new leg-vein method is given. The symptoms described are identical with those of the subcutaneous and new intramuscular methods, except that they appear a little earlier. One table of typical results indicates that respiratory failure is the primary cause of death. Another table is a summary of minimum lethal and minimum systolic standstill doses obtained on four tinctures by guinea-pig and frog methods. Analysis of the latter table shows that the minimum lethal dose in the leg-vein method is smaller than that in the subcutaneous method. Since heart beats could be felt through chest wall for some time after respiration had ceased the author questions the soundness of Richaud's conclusion that respiratory failure makes the guinea pig valueless as an assay animal for digitalis which is mainly used for its effect on the heart. Dale and Burn have emphasized that a test does not have to be identical with therapeutic effect so long as it measures the active principle. The subcutaneous, new leg-vein and new intramuscular guinea pig methods have the advantage that anesthesia is unnecessary, artificial respiration is not employed, and operative procedure is less severe. All three guinea pig methods give good results but time and technique affect preference.—*JAMES H. DEFANDORF J Am Pharm Assoc* 24 (1935), 276 (Z M C)

Digitalis—U S P Standards for The U S P X standard and the standards of some other pharmacopœias are stated. The present standard for U S P digitalis is about four fifths that of the International Standard and there are serious objections to maintaining it. It furnishes a market for digitalis that does not meet requirements of the European markets. Standards must be attainable and if the International Standard is adopted for U S P XI they can be easily met. The author has produced a dried leaf of twice the activity of the U S P standard and to adopt the International Standard means raising the present standard 25 to 30%. If that were done tincture of digitalis U S P XI would be equal in strength to that official in many leading European countries. The value of a standard powder in bringing together the results of different workers has been emphasized previously. There is no unanimity on the question of biological testing of digitalis. It is well known that tincture of digitalis tested on frogs at intervals of three months or more will show much greater loss in strength than when tested at similar intervals on cats. This has been demonstrated by Wokes, Foster and Van Dyke who studied the effect of aging found losses by both assay methods but much greater in the frog method. The cat method has the advantage also that it affords a means of calculating the physiological dose for a patient. Adoption of the International Standard for digitalis in U S P XI and the recognition of 100 mg of this powder as an International Unit using cats as test animals, would provide physicians with products whose dose would be easily calculated by the method of Eggleston. A national Standard Digitalis Powder for the United States should be prepared from mixed powdered leaves from different sources and it would not be necessary to adjust to the International Standard but simply to determine the ratio between the potencies of the two standard powders. Adoption of the International Standard would simply require a definition for the unit of digitalis as the amount of activity contained in 0.1 Gm of the International Standard Digitalis Powder so that 1 Gm of the International Standard represents 10 units.—*F A UPSHER SMITH J Am Pharm Assoc* 24 (1935) 272 (Z M C)

1-2-4 Dinitrophenol—Blood Sugar Changes after Dinitrophenol causes hyperglucemia in dogs when injected subcutaneously. It also increases the rate at which glucose is removed from

the blood after quantities of the latter have been given intravenously—W F ASHE, JR *Proc Soc Exptl Biol Med*, 32 (1935), 1062 (A E M)

1-2-4 Dinitrophenol—Effect of, on Oxygen Uptake of Rat Tissue Neither treatment of the animals with dinitrophenols while still alive nor action of the substance on the tissue in Ringer's solution caused a definite change in the oxygen uptake—EDWARD MUNTWYLER *Proc Soc Exptl Biol Med*, 32 (1935), 1060 (A E M)

2-4 Dinitrophenol—Effects of, on Respiration of Commercial Cake Yeast Dinitrophenol at a given concentration will either stimulate or inhibit the respiration of yeast depending on the pH level Only the undissociated form is of influence—J FIELD, 2ND, A W MARTIN and S M FIELD *Proc Soc Exptl Biol Med*, 32 (1935), 1043 (A E M)

Insulin—Blood Sugar Curves in Normal and Diabetic Dogs after Intravenous Injections of The minimum of blood sugar in the normal dog is reached after 20-30 minutes Return to normal follows within 90 minutes Doses of 0.3 units per Kg cause in the diabetic dog decreases from 40-80% lasting one hour or more, with prolonged time of return to normal The development of diabetic conditions could be shown already 18 hours after pancreatectomy, but the final curve was obtained only after 138 hours—B N BERG J GROSS, J MCAFEE and T F ZUCKER *Proc Soc Exptl Biol Med*, 32 (1935), 1080 (A E M)

Insulin, Irradiated—Stimulation of the Adrenal Medulla by Insulin irradiated with X-rays has no influence on the blood sugar It causes, however, a pronounced decrease in blood amino acids in normal animals This effect does not appear, when the adrenal medulla is destroyed—J MURRAY LUCK and GORDON M RICHMOND *Proc Soc Exptl Biol Med*, 32 (1935), 1056 (A E M)

Oysters—Food Value and Anti-Anemic Power of Comparative blood tests were carried out on dogs that were fed on diets with and without oysters, respectively The results consistently confirmed Pease's results on the anti anemic value of oysters—LÉON BINET and V STRUMZA *Paris-Medical*, 23 (1933), No 26, 28, through *Bull Soc Sci Hyg Aliment* 23 (1935) 53 (A P-C)

Quinine—Effect of, on Circulatory System. The injection of 2 mg quinine ethanesulphonate in 2 cc physiologic sodium chloride solution into the femoral artery of the paw of a dog anesthetized with chloralose, bivagotomized at the neck and submitted to artificial respiration increased the rate of blood flow approximately 5 fold This vasodilation lasted a rather long time since 2 minutes after the beginning of the action of quinine the rate of blood flow was still about twice as fast as before injection—RAYMOND HAMET *Compt rend soc biol*, 118 (1935) 231, through *Squibb Abstract Bull*, 8 (1935) A 551

Sodium Bromide—Experimental Study of Toxicity of, in Intravenous Injection From experiments on rabbits and clinical observations it is concluded that the toxicity of sodium bromide is relatively small, while the dose that can be supported safely is variable, it would seem that with a dose of less than 1 Gm per Kg body weight (in rabbits) there is no danger of accidents Sodium bromide has a marked anesthetic action, but insufficient to permit of serious operations it must be completed by a general anesthesia, which is however, rendered easier and free from danger High blood pressure or kidney troubles may in some cases contraindicate the use of sodium bromide—A PATOR and G PATOR *Ann Med Legale Criminol Police Sci* 15 (1935) 53-58 (A P-C)

Vitamin E—Vestibular Function Test for, Deficiency in the Rat. The vestibular test consists in at least 3 successive observations of nystagmus duration the direction of rotation being reversed after each observation The durations of nystagmus following clockwise rotations are averaged and similarly the durations following counter clockwise rotations The mean of these two averages is taken as a result of the test Normal animals give a nystagmus duration of 7-10 seconds during the period of rapid growth, diminishing to 5-8 seconds after maturity Vitamin B deficient animals show a progressive increase in the duration of nystagmus following the standardized rotation which becomes significant in the third week and reaches a value of 12-16 seconds before the appearance of any other neurologic symptom—C F CHURCH U S P Pharmacopœial Conference Committee on Vitamin B₁ Standardization Bulletin 7 (3/12/35), 35, through *Squibb Abstract Bull* 8 (1935), A-520

TOXICOLOGY

Cinchophen—Peptic Ulcers Produced by Feeding, to Mammals Other Than the Dog Cats are very susceptible to cinchophen, guinea pigs moderately and rabbits very resistant—S O SCHWARTZ and J P SIMONDS *Proc Soc Exptl Biol Med* 32 (1935), 1133

(A E M)

Poisonings—Common, in General Practice The author reviews cases of poisoning common in general practice including methods of treatment and the symptoms. Specifically he includes poisoning from carbon monoxide bromides iodides arsenic mercury barbituric acid compounds amidopyrine dinitrophenol cinchophen phenolphthalein, lead and benzene in industrial poisoning and poisoning from cosmetics and dyes—V F STOCK *Bull Acad Med Toronto* 8 (1935) 126, through *Squibb Abstract Bull*, 8 (1935), A 549

Tartar Emetic—Effects of, on the Leukocyte Count Following intravenous inoculation with 1% solution of potassium antimonyl tartrate the leukocyte count was reduced in 6 of 9 patients who exhibited leukocytoses of abnormal cells—S P LUCIA *Proc Soc Exptl Biol Med* 32 (1935) 1109

(A E M)

THERAPEUTICS

Amebiasis—Observation on Antigens for Complement Fixation in The mucoid material from the infected intestine of dogs is extracted with absolute alcohol (7 parts) at 45° for 15 days. The filtered solution is diluted with 3 to 5 parts of normal saline and tested for hemolytic anti-complementary and antigenic properties. It is as active as extracts prepared from cultures of *E histolytica*—CHAS F CRAIG and L C SCOTT *Proc Soc Exptl Biol Med* 32 (1935), 958

(A E M)

Calcium—Relation of, to Blood Formation The presence of calcium in the diet deficient in certain other organic elements both cures and prevents the development of the expected polycythemia and concomitant chronic anemia—JAMES M ORTEN, ARTHUR H SMITH and LAFAYETTE B MENDEL *Proc Soc Exptl Biol Med*, 32 (1935), 1093

(A E M)

Diphtheria—Hyperglucemia in Carbohydrate Metabolism and Treatment with Dextrose-Insulin The deviation of glucemia during diphtheria can be either way and is generally of little significance. The glucose tolerance however, shows frequently a disturbance especially in severe cases. The disturbance is of hepatic origin. Insulin is of no value—ISAAC NATIN and CORNELIA DA RIN *Semana med (Buenos Aires)* 42 (1935), 1055

(A E M)

Drugs—Dynamic Action of The author discusses the action of drugs in different dilutions and classifies the different types of symptoms involved in the prescribing of remedies—THOMAS M STEWART *J Am Inst Homeop*, 28 (1935), 208, through *Squibb Abstract Bull*, 8 (1935) A 535

Drugs—Rationale of New Uses for Some Old Considering some of the old drugs for which more extended uses have been found attention may be directed to carbon dioxide. The therapeutic applications of the respiratory functions of carbon dioxide are many and varied. When the depressed respiratory center requires stronger stimulation in cases of narcotic poisoning carbon dioxide is beneficial. It is used in the early stages of anesthesia to increase the respiratory excursion and to stimulate the absorption of the anesthetic and after anesthesia to increase the depth of breathing. Carbon dioxide has been used in cases of asthma and hay fever, in which it is suggested that the increased hydrogen ion concentration of the blood reduces the sensitivity of the tissues to anaphylactic stimulants. Frequently the virtue of a drug depends on some physical phenomenon such as its osmotic tension in solution. The purgative effects of magnesium sulphate depend on this fact. Another physical property that of adsorption is responsible for a restoration to popularity of certain drugs. The virtue of kaolin depends on the large surface exposed by a quantity of the drug in a colloidal state of fineness by means of which it adsorbs bacteria and toxins alkaloids putrefactive amines ptomaines etc thus delaying or preventing absorption from the bowel. A more recent application of its adsorbent qualities is to employ it by insufflation to nose and throat for removing bacteria in diphtheria carriers. Recent research has indicated a new use for copper in the form of the sulphate or other ionizable salt. Such regards copper as a biological catalyst for the utilization of iron in the synthesis of hemoglobin. Many other instances of new uses for old drugs are given in the article—B L STANTON *Australasian J Pharm* 16 (1935) 174

NEW REMEDIES

SYNTHETICS

Analeptin—Preparation and Chemical Composition of Synthetic Description of the most important synthetic stimulants such as adrenaline, caffeine, camphor, hexeton, Cardiazol, Cornin and also of a new synthetic "Analeptin" (tetrahydrocaroyliden 2 menthanonamine) is given. Analeptin in doses of 0.01 Gm. exercises a stimulating action on respiration, heart and blood circulation systems. According to the chemical structures, it is composed from some 25 chemical substances and its first analytical reaction is due to its iso or heterocyclic benzene ring and then secondly through hydration of the same. A ring with a carbonyl group has a weak cardiac action, and a ring with alkyl group has a strong cardiac action.—J. ERDOS, *Magyar Gyógyszeres Tudományi Társaság Értesítője*, 10 (1934), 407-423, through *Chem. Zentr.*, 106 (1935), 926.

(G B)

Dyes—Study of Injectable A study of the dyes, gentian violet and methylene blue was made. The above dyes were free from any poisonous metals such as arsenic, lead and zinc. However, some iron was present which was not objectionable. The above metals may be present due to the method of preparation of the dyes. One per cent solutions of the dyes were injected into the marginal vein of 2.5 Kg. rabbits. Results obtained indicate methylene blue injections may be of value in the treatment of leprosy. The dyes were mixed with solutions of disodium phosphate, sodium acetate, sodium citrate, sodium glycerophosphate, sodium caedylate and sodium chaulmoograte, and test injections made. A mixture of methylene blue and sodium chaulmoograte appeared to be of interest. This mixture was prepared as follows: a solution containing 10 Gm. of methylene blue, 10 cc. N/10 sodium hydroxide and 500-cc. saccharose (94 parts in 1000 cc.) is mixed with a solution containing 250 cc. N/10 sodium chaulmoograte, made up to 500 cc. with a solution of saccharose (94 parts in 1000). The resulting mixture will have a pH of 7.24 and should be injected as rapidly as possible.—J. C. PEIRER, *J. pharm. chim.* 21 (1935), 389.

(M M Z)

Esmodil (Bayer I. G. Farbenindustrie Aktiengesellschaft, Leverkusen) is chemically pure trimethylmethoxypropenylammonium bromide. It is a white, crystalline powder melting at 109° C. and is very soluble in water and in alcohol. It is a specific intestinal peristaltic and is indicated in intestinal atony and in post-operative urine suppression. The usual dose is the intramuscular or subcutaneous injection of 1 cc. of a 3% isotonic solution.—*Pharm. Ztg.*, 80 (1935), 311.

(G E C)

Prontosil (Bayer I. G. Farbenindustrie Aktiengesellschaft, Leverkusen a. Rhein) is the hydrochloride of 4-sulphonamide 2',4'-di-amino azo benzene. $\text{HNO}_2\text{S} \text{---} \text{C}_6\text{H}_4 \text{---} \text{N}=\text{N} \text{---} \text{C}_6\text{H}_4 \text{---} \text{NH}_2$

 NH_2

NH_2HCl . It is moderately soluble in cold water, alcohol and acetone and melts with decomposition at 247° to 251° C. It is dispensed in tablets containing 0.3 Gm. of prontosil mixed with starch and talc and also in solutions containing 0.05 Gm. prontosil and 0.85 Gm. dextrose per 20 cc. The preparation is recommended for use against septic angina, septic scarlet fever, septic diphtheria, erysipelas, polyarthritis rheumatica and postpartum sepsis. Intravenously, it does 10 to 20 cc. daily. Orally 1 to 2 tablets are given daily to supplement injection therapy. A 1% to 2% solution is also used for disinfection of the oral cavity.—*Pharm. Ztg.*, 80 (1935), 276. (G E C)

Redoxon (Hoffmann-La Roche and Co. A. G. Berlin) is synthetic vitamin C. It is marketed in tablet form, each tablet containing 50 mg. of the vitamin.—*Deut. Med. Wochenschr.* 61 (1935), 178. (H R)

SPECIALTIES

Algoln Tablets (R. E. Müller & Co., Berlin-Pankow) consist of acetylsalicylic acid, lithium carbonate, quinine hydrochloride and phenylquinoline carbonic acid. They are used for neuralgia, migraine, headache, lumbago, rheumatism and grippe. 1 to 2 tablets are to be taken two to four times a day.—*Pharm. Ztg.*, 80 (1935), 299. (G I C)

Ambinon is an extract prepared from the anterior lobe of the pituitary gland and contains thyroid activating and gonad stimulating hormones, both hormones being standardized by biological tests. Ambinon is indicated in obesity, menstrual disorders, gonad dysfunction and

infantilism The dose recommended is one ampul daily Ambinon is supplied in powder form in ampuls with the corresponding number of ampuls of sterile distilled water to be used as solvent It is issued in boxes containing three ampuls—*Quart J Pharm Pharmacol*, 8 (1935), 157

(S W G)

Amphopulmon Ampuls (Chem Fabrik F L Kwizda, Korneuburg) is a sterile solution of purified basic quinine, camphor, menthol, in a mixture of ethereal and fatty oils—*Pharm Presse*, 40 (1935), 105

(M F W D)

Amphyl is a non corrosive antiseptic which is non irritant, and non staining, and has a low toxicity Its coefficient against *B typhosus* is 12.4 and against *Staph aureus* 5.6 It is claimed to be uniform in action against a wide range of pathogenic organisms, and to be efficient in the presence of organic matter Amphyl has a low surface tension which remains constant for all the recommended dilutions A slight cloudiness is formed with hard water A strength of 0.5 to 1% should be used for lotions, douches and gargles, but for sterilization of instruments and rubber gloves a 2% solution is required The solutions are odorless and do not cause irritation when applied to broken or unbroken skin surfaces Amphyl is supplied in 4 oz., 16 oz. and 32 oz. bottles, and in 1-gallon tins—*Quart J Pharm Pharmacol*, 8 (1935), 157

(S W G)

Animal Charcoal Pills (Dr Kronik and Ph Mr Edels, Vienna, 7 dist.) Each contains 0.25 Gm animal charcoal along with magnesium sulphide, 20 to a package—*Pharm Presse* 40 (1935), 105

(M F W D)

Antrypol is the symmetrical ureide of the sodium salt of *m* aminobenzoyl *m* amino *p* methyl benzoyl 1 naphthyl amino 4.6.8 trisulphate It is recommended for the treatment of trypanosomiasis, and it is claimed that its use does not cause ocular lesions which are often a sequel to the arsenical treatment Antrypol is effective alone if given in the early stages of infection by *T gambiense*, but in infections by *T Rhodesiense*, and in all cases in which the infection has reached the central nervous system combined treatment with an arsenical preparation is recommended Best results are obtained by intravenous injection, one every third day, first injection 1 Gm second injection 2 Gm and four injections of 3 Gm If there is nephritis, smaller doses are suggested but nothing less than 5 to 10 injections of 1 Gm each is likely to be of any permanent value Antrypol is supplied in boxes of 6 tubes containing 1 Gm, 2 Gm or 3 Gm, and in bottles containing 50 Gm—*Quart J Pharm Pharmacol*, 8 (1935), 157

(S W G)

Aquiox tonic tablets are composed of a concentrate prepared from the tips of selected seaweeds It contains in balanced proportions potash, soda, lime, magnesia, iron, chlorine, iodine, sulphur in various forms, phosphates, carbonates, sulphates, nitrogen and carbon compounds Aquiox is recommended as a general tonic The tablets are supplied sugar coated and also talc coated in bottles of three sizes—*Quart J Pharm Pharmacol*, 8 (1935), 158

(S W G)

Bellergal (Sandoz A G Nurnberg) is supplied in the form of coated tablets containing 0.3 mg ergotamine 0.1-mg Bellafofin and 20 mg phenyl-ethyl barbituric acid—*Deut Med Wochschr*, 61 (1935), 176

(H R)

Bronchovydrin Ointment is composed of papvydrin (papaverine cumydrine) small quantities of adrenal hormones, hypophysis extract and nitrates in an ointment base with a slightly acid reaction It is recommended for the treatment of hay fever and other allergic conditions causing nasal catarrh—*Quart J Pharm Pharmacol*, 8 (1935), 158

(S W G)

Calmosine is the trade name given by Kon Pharm Fabrieken Brocades & Steeman and Pharmacia (Netherlands) to amidopyrine diethylbarbiturate—*Pharm Weekblad*, 72 (1935), 867

(E H W)

Calsimil tablets contain in each 10 grain tablet 5 grains of calcium sodium lactate and 500 international units of pure crystalline vitamin D It is claimed that this preparation presents the calcium in a readily assimilable form and the vitamin D ensures that a large proportion of the calcium absorbed is retained in the reserve depots of the system for future utilization Calsimil is suggested for the treatment of chilblains, general debility, certain skin affections, pregnancy and other disorders due to calcium deficiency The dosage is 1 to 6 tablets daily which can be swallowed or dissolved in the mouth Calsimil is supplied in bottles of 60 tablets—*Quart J Pharm Pharmacol*, 8 (1935), 158

(S W G)

Citro-Gold (Pharm Laboratorium K Badenberg, Essen Steele), a preparation of lemon witch hazel, glycerin and boric acid is used for coarse and chapped skins—*Pharm Zentralk* 76 (1935), 180

(E V S)

Crnex is a total extract of ovary, in liquid form for administration by mouth. It is prepared from the ovaries of young animals and is rich in folliculin and contains all the other hormones. It is soluble in water and does not lose its activity in the presence of acid, alkali or alcohol. It is not attacked by pepsin or trypsin. It is indicated in conditions of partial or total lack of ovarian secretion. Crnex is standardized to contain 30 mouse units per cc. The average dose is 12 to 25 drops per day taken in 2 or 3 doses between meals. Crnex is supplied in bottles containing 240 mouse units (approximately 280 drops). —*Quart J Pharm Pharmacol*, 8 (1935) 158 (S W G)

Cysteine Hydrochloride, Buffered (E R Squibb & Sons, New York, N Y) ampuls containing cysteine hydrochloride with sufficient sodium borate so that when diluted they yield a solution of about pH 4. It is used as a wet dressing on varicose ulcers, traumatic ulcers, post-operative wounds, suppurated carbuncles, decubital and trophic ulcers and extensively denuded surfaces upon which skin grafting has been unsuccessful. It is contraindicated in cases of malignant ulcerations or those classed as premalignant lesions and X-ray dermatitis. It is marketed in packages of five 0.5 Gm ampuls and 5 Gm ampuls. —*Drug Circ*, 70 (May 1935), 29 (T G W)

Darmiol (Homöopathische Centralapothek e gegr 1865 von Prof Dr Mauchl, Goppingen) is a pure acid free mineral oil flavored with peppermint. It is useful for intestinal sluggishness and stubborn constipation. —*Pharm Zentrall*, 76 (1935), 180 (E V S)

Diffundol-Salbe (Diffundol G m b H Frankfurt a M, Sud) is a specially prepared soda soap with the addition of ethereal oils, rectified oil of turpentine, sulphur compounds and formaldehyde. It is used for rheumatism, gout, ischias and arthritis deformans. —*Pharm Zentrall*, 76 (1935) 215 (E V S)

Diphtheria-Formol-Toxoid SS Dresden (Sächsisches Serumwerk A G, Dresden) is an albumin free serum, the antigen value of which is unaltered by the addition of formaldehyde. It may be used subcutaneously or intramuscularly. —*Pharm Zentrall*, 76 (1935), 180 (F V S)

Diphtheria-Toxin-Antitoxin-Gemische neutral T A SS Dresden (Sächsisches Serumwerk A G, Dresden) is an active neutral immunizing mixture of diphtheria toxin and antitoxin from cattle or horses used for subcutaneous inoculation. Phenol (0.5%) is used as a preservative. —*Pharm Zentrall*, 76 (1935), 181 (E V S)

Dolosin (Friedrich Apotheke O Gerlach, Berlin O 112) preparations are marketed in capsule form as follows: Dolosin A for headaches (dimethylaminopyrazolone, phenacetin, acetylsalicylic acid), Dolosin G for the grippe (phenacetin, dimethylaminopyrazolone, quinine hydrochloride, acetylsalicylic acid), Dolosin N for neuralgias (caffeine, phenacetin, dimethylaminopyrazolone, acetylsalicylic acid), Dolosin O for toothaches (amidopyrine, acetylsalicylic acid, veramon). —*Pharm Zentrall*, 76 (1935), 181 (E V S)

Draconal (Dr R E Muller & Co, Berlin Pankow) is a sedative tablet containing 0.23 Gm of diethylbarbituric acid, 0.15 Gm of bromisovalerianylurea, and 0.12 Gm of paraacetophenetidin. —*Pharm Zentrall*, 76 (1935) 215 (E V S)

Elixir Alycin (Wm S Merrell Co, Cincinnati, Ohio), an elixir containing 4 1/2 grains of salicylate and 9 grains of alkali in an elixir base. It is used in conditions where salicylates are indicated: colds, tonsillitis, influenza, neuralgic complaints, rheumatism and arthritis. It is supplied in 4- and 16-ounce bottles. —*Drug Circ*, 70 (April 1935) 30 (T G W)

Erinol (Pfau Apotheke Th Thurn Mainz) an inhalant for colds and throat catarrh is composed of refined camphor, menthol, vanilla oil and purified paraffin oil. —*Pharm Zentrall*, 76 (1935) 181 (I V S)

Esmodil (Bayer I G Farbenindustrie A G, Leverkusen a Rh) an injectable intestinal tonic is a 1 cc ampul containing a 3 parts per million aqueous isotonic solution of trimethylmethoxypropylammonium bromide. It is used in intestinal atony after laparotomy or other difficult operative interferences, in infectious diseases with peritoneal irritation after childbirth or septic abortions. —*Pharm Zentrall*, 76 (1935) 215 (I V S)

Eubion is a vitamin A concentrate issued in the form of chocolate tablets. The vitamin A concentrate has an activity of approximately 10,000 Carr Price units and each tablet is equivalent in vitamin A to one tablespoonful (14.2 cc) of best quality cod liver oil with a suitable amount of vitamin D. It is claimed to be not only of considerable value to growing children but also a

useful prophylactic against common cold in adults Eubion does not cause gastric disorder, and can be given where cod liver oil cannot be tolerated One or two tablets daily is recommended for children In severe infections in adults, four or five tablets may be given daily Eubion is issued in tins of 24 tablets—*Quart J Pharm Pharmacol*, 8 (1935), 159 (S W G)

Eupragin (Chem Fabrik Aethyha G m b H, Mainz) ampuls contain sodium sulphate (4.8%) and potassium sodium tartrate (1%) It is indicated for muscular rheumatism and lumbago—*Pharm Zentralh*, 76 (1935), 181 (L V S)

Gadoment (E L Patch Co, Boston, Mass) Gadus Ointment (Patch) is a preparation of cod liver oil for the treatment of burns and other skin lesions It is reported by the manufacturer to contain specially treated cod liver oil 70%, phenol 0.375% in a special wax base Marketed in tubes, one pound and five pound containers (S W G)

Gastro-Lymphon (Bineuco G m b H, Weisbaden) an intestinal regulator, is composed of Ext Colombo, gentian, juniper, condurango, curcuma, chamomile, peppermint, potassium bromide, potassium bicarbonate, arsenic and formaldehyde—*Pharm Zentralh*, 76 (1935), 181 (L V S)

Genitone (Win S Merrell Co Cincinnati, Ohio) The green drugs of *riburnum prunifolium*, *passiflora incarnata* and *pulsatilla*, together with colorless hydrastis, in an aromatic cordial Its action is that of a mild sedative, anti spasmodic and analgesic and it is indicated in the treatment of amenorrhea, dysmenorrhea, menorrhagia and during puberty and the climacteric It is supplied in pint bottles—*Drug Circ*, 79 (May 1935), 28 (T G W)

Glucostrophin (Labopharma Dr Laboschin G m b H Berlin) is marketed in two strengths the weaker containing 20% of glucose and 0.00025 Gm of strophanthin, while the stronger contains 0.0005 Gm of strophanthin—*Pharm Zentralh*, 76 (1935), 105 (E V S)

Glutamuron (Calco Chemical Co Inc, Bound Brook, N J) A combination of glutamic acid, ferrous glutamate and ferrous chloride each tablet containing 75 mg of available iron This material must be given under the care of a physician and continued laboratory work is essential to check the results It is used as a hematinic and gastric stimulant It is supplied in bottles of 100, 500 and 1000 tablets—*Drug Circ*, 79 (April 1935), 30 (T G W)

Goebin (Heinr Adolf Goebel Steinhagen in Westf), a preparation of diluted spirits mucilage of acacia and precipitated sulphur, is used for skin eruptions—*Pharm Zentralh*, 76 (1935), 181 (E V S)

Gonococcus Filtrate, Corbus-Ferry (Parke, Davis & Co, Detroit, Mich) is a standardized bouillon filtrate of the gonococcus, containing the soluble specific extracellular toxin, and designed for intradermal injection It is claimed to develop specific active immunity against the gonococcus It is indicated in both acute and chronic cases of gonorrheal infection It is supplied in packages containing a 2-cc vial of filtrate and a 2-cc vial of diluent—*Drug Circ*, 79 (May 1935), 28 (T G W)

Gynergen (Sandoz Chemical Works, Inc Distributors E Fougere & Co, Inc) Ergotamine tartrate in the pure and stable form The ampul solution produces a prolonged tonic uterine contraction and is painless and non-irritant It is employed in obstetrics and gynecology to prevent or control uterine hemorrhage, in the puerperium to favor involution and prevent puerperal complications, in sympatheticotomies such as migraine headache to relieve acute seizures It is supplied in 0.5-cc and 1 cc ampuls, 0.001-Gm tablets, and 0.1% solution—*Drug Circ*, 79 (April 1935), 31 (T G W)

Halicaps (Norwich Pharmacal Co, Norwich, N Y) Each capsule contains not less than 3 minims of habibut liver oil, vitamin tested to contain not less than 55,100 units of vitamin A and 767 units of vitamin D per Gm Each capsule is the equivalent in vitamin A of at least four teaspoonfuls of standard cod liver oil and contains not less than 9414 units of vitamin A and not less than 131 units of vitamin D It is indicated in rundown conditions due to a deficiency of vitamin A It is supplied in boxes of 50 capsules—*Drug Circ*, 79 (April 1935), 31 (T G W)

Halmagon is a combination of the halogen salts of magnesium It is supplied as tablets for oral administration, as an emulsion for intramuscular injection and as an isotonic solution for rectal injection Each tablet contains magnesium chloride 0.395 Gm, magnesium bromide 0.0133 Gm, magnesium iodide 0.00067 Gm, magnesium fluoride 0.006 Gm, made up to 0.45 Gm with excipient Each ampul of the emulsion contains in 5 cc approximately 34 grains of halogen salts consisting of chloride 2.137 Gm, bromide 0.58 Gm, iodide 0.00039 Gm, fluoride 0.00028 Gm

Crinex is a total extract of ovary, in liquid form for administration by mouth. It is prepared from the ovaries of young animals and is rich in folliculin and contains all the other hormones. It is soluble in water, and does not lose its activity in the presence of acid, alkali or alcohol. It is not attacked by pepsin or trypsin. It is indicated in conditions of partial or total lack of ovarian secretion. Crinex is standardized to contain 30 mouse units per cc. The average dose is 12 to 25 drops per day taken in 2 or 3 doses between meals. Crinex is supplied in bottles containing 240 mouse units (approximately 280 drops)—*Quart J Pharm Pharmacol*, 8 (1935) 158 (S W G)

Cysteine Hydrochloride, Buffered (E R Squibb & Sons, New York, N Y) Ampuls containing cysteine hydrochloride with sufficient sodium borate so that when diluted they yield a solution of about pH 4. It is used as a wet dressing on varicose ulcers, traumatic ulcers, post-operative wounds, suppurated carbuncles, decubital and trophic ulcers and extensively denuded surfaces upon which skin grafting has been unsuccessful. It is contraindicated in cases of malignant ulcerations or those classed as premalignant lesions, and X-ray dermatitis. It is marketed in packages of five 0.5 Gm ampuls and 5 Gm ampuls—*Drug Circ*, 79 (May 1935) 29 (T G W)

Darmiol (Homoopathische Centralapotheke, gegr. 1865 von Prof. Dr. Mauch, Goppingen) is a pure acid-free mineral oil flavored with peppermint. It is useful for intestinal sluggishness and stubborn constipation—*Pharm Zentralk*, 76 (1935) 180 (E V S)

Diffundol-Salbe (Diffundol G.m.b.H. Frankfurt a.M. Sud.) is a specially prepared soda soap with the addition of ethereal oils, rectified oil of turpentine, sulphur compounds and formaldehyde. It is used for rheumatism, gout, ischias and arthritis deformans—*Pharm Zentralk*, 76 (1935) 215 (E V S)

Diphtheria-Formol-Toxoid SS Dresden (Sächsisches Serumwerk A.G. Dresden) is an albumin-free serum, the antigen value of which is unaltered by the addition of formaldehyde. It may be used subcutaneously or intramuscularly—*Pharm Zentralk*, 76 (1935) 180 (E V S)

Diphtheria-Toxin-Antitoxin-Gemische neutral T A SS Dresden (Sächsisches Serumwerk A.G., Dresden) is an active neutral immunizing mixture of diphtheria toxin and antitoxin from cattle or horses used for subcutaneous inoculation. Phenol (0.5%) is used as a preservative—*Pharm Zentralk*, 76 (1935) 181 (E V S)

Dolosin (Friedrich Apotheke, O. Gerlach, Berlin O 112) preparations are marketed in capsule form as follows: Dolosin A for headaches (dimethylaminopyrazolone, phenacetin, acetyl salicylic acid), Dolosin G for the grippe (phenacetin, dimethylaminopyrazolone, quinine hydrochloride, acetylsalicylic acid), Dolosin N for neuralgias (caffeine, phenacetin, dimethylaminopyrazolone, acetylsalicylic acid), Dolosin O for toothaches (amidopyrine, acetylsalicylic acid, veramon)—*Pharm Zentralk*, 76 (1935), 181 (E V S)

Draconal (Dr. R. E. Müller & Co., Berlin Pankow) is a sedative tablet containing 0.23 Gm of diethylbarbituric acid, 0.15 Gm of bromisovalerianylurea, and 0.12 Gm of paraacetphenetidin—*Pharm Zentralk*, 76 (1935) 215 (E V S)

Elixir Alycin (Wm. S. Merrell Co., Cincinnati, Ohio) an elixir containing $4\frac{1}{2}$ grains of salicylate and 9 grains of alkali in an elixir base. It is used in conditions where salicylates are indicated, colds, tonsillitis, influenza, neuralgic complaints, rheumatism and arthritis. It is supplied in 4- and 16-ounce bottles—*Drug Circ*, 79 (April 1935) 30 (T G W)

Erinol (Pfau Apotheke, Th. Thurn, Mainz) an inhalant for colds and throat catarrh, is composed of refined camphor, mentho, vanilla oil and purified paraffin oil—*Pharm Zentralk*, 76 (1935), 181 (E V S)

Esmodil (Bayer, I. G. Farbenindustrie A.G., Leverkusen a. Rh.) an injectable intestinal tonic is a 1 cc ampul containing a 3 parts per million aqueous isotonic solution of trimethylmethoxypropenylammonium bromide. It is used in intestinal atony after laparotomy or other difficult operative interferences, in infectious diseases with peritoneal irritation after childbirth or septic abortions—*Pharm Zentralk*, 76 (1935) 215 (E V S)

Eubion is a vitamin A concentrate issued in the form of chocolate tablets. The vitamin A concentrate has an activity of approximately 10,000 Carr-Price units, and each tablet is equivalent in vitamin A to one tablespoonful (14.2 cc) of best quality cod liver oil, with a suitable amount of vitamin D. It is claimed to be not only of considerable value to growing children but also a

useful prophylactic against common cold in adults Eubion does not cause gastric disorder, and can be given where cod liver oil cannot be tolerated One or two tablets daily is recommended for children In severe infections in adults, four or five tablets may be given daily Eubion is issued in tins of 24 tablets—*Quart J Pharm Pharmacol*, 8 (1935), 159 (S W G)

Eupragin (Chem Fabrik Acthylia G m b H, Mainz) ampuls contain sodium sulphate (4.8%) and potassium sodium tartrate (1%) It is indicated for muscular rheumatism and lumbago—*Pharm Zentralh*, 76 (1935), 181 (E V S)

Gadoment (L L Patch Co, Boston, Mass) Gadus Ointment (Patch) is a preparation of cod liver oil for the treatment of burns and other skin lesions It is reported by the manufacturer to contain specially treated cod liver oil 70%, phenol 0.375% in a special wax base Marketed in tubes, one pound and five pound containers (S W G)

Gastro-Lymphon (Bineuco G m b H, Weisbaden), an intestinal regulator, is composed of Ext Colombo, gentian, juniper, condurango, eucema, chamomile, peppermint, potassium bromide, potassium bicarbonate, arsenic and formaldehyde—*Pharm Zentralh*, 76 (1935), 181 (E V S)

Gentone (Win S Merrell Co, Cincinnati, Ohio) The green drugs of *virburnum prunifolium*, *passiflora incarnata* and *pulsatilla*, together with colorless hydrastis, in an aromatic cordial Its action is that of a mild sedative, anti spasmodic and analgesic and it is indicated in the treatment of amenorrhea, dysmenorrhea, menorrhagia and during puberty and the climacteric It is supplied in pint bottles—*Drug Circ*, 79 (May 1935), 28 (T G W)

Glucostrophin (Labopharma Dr Laboschin G m b H, Berlin) is marketed in two strengths the weaker containing 20% of glucose and 0.00025 Gm of strophanthin, while the stronger contains 0.0005 Gm of strophanthin—*Pharm Zentralh*, 76 (1935), 105 (E V S)

Glutamiron (Calco Chemical Co Inc, Bound Brook, N J) A combination of glutamic acid, ferrous glutamate and ferrous chloride, each tablet containing 75 mg of available iron This material must be given under the care of a physician and continued laboratory work is essential to check the results It is used as a hematinic and gastric stimulant It is supplied in bottles of 100, 500 and 1000 tablets—*Drug Circ*, 79 (April 1935), 30 (T G W)

Goebin (Heinr Adolf Goebel Steinhagen in Westf), a preparation of diluted spirits, mucilage of acacia and precipitated sulphur is used for skin eruptions—*Pharm Zentralh*, 76 (1935), 181 (E V S)

Gonococcus Filtrate, Corbus-Ferry (Parke, Davis & Co, Detroit, Mich) is a standardized bouillon filtrate of the gonococcus, containing the soluble specific extracellular toxin, and designed for intradermal injection It is claimed to develop specific active immunity against the gonococcus It is indicated in both acute and chronic cases of gonorrheal infection It is supplied in packages containing a 2 cc vial of filtrate and a 2 cc vial of diluent—*Drug Circ*, 79 (May 1935), 28 (T G W)

Gynergen (Sandoz Chemical Works, Inc Distributors E Fougere & Co, Inc) Ergotamine tartrate in the pure and stable form The ampul solution produces a prolonged tonic uterine contraction and is painless and non-irritant It is employed in obstetrics and gynecology to prevent or control uterine hemorrhage, in the puerperium to favor involution and prevent puerperal complications, in sympathicotomies such as migraine headache to relieve acute seizures It is supplied in 0.5 cc and 1-cc ampuls, 0.001-Gm tablets, and 0.1% solution—*Drug Circ*, 79 (April 1935), 31 (T G W)

Halicaps (Norwich Pharmacal Co, Norwich, N Y) Each capsule contains not less than 3 minims of halibut liver oil, vitamin tested to contain not less than 55,100 units of vitamin A and 767 units of vitamin D per Gm Each capsule is the equivalent in vitamin A of at least four teaspoonfuls of standard cod liver oil and contains not less than 9414 units of vitamin A and not less than 131 units of vitamin D It is indicated in rundown conditions due to a deficiency of vitamin A It is supplied in boxes of 50 capsules—*Drug Circ*, 79 (April 1935), 31 (T G W)

Halmagon is a combination of the halogen salts of magnesium It is supplied as tablets for oral administration, as an emulsion for intramuscular injection and as an isotonic solution for rectal injection Each tablet contains magnesium chloride 0.395 Gm, magnesium bromide 0.0133 Gm, magnesium iodide 0.00067 Gm, magnesium fluoride 0.006 Gm, made up to 0.45 Gm with excipient Each ampul of the emulsion contains in 5 cc approximately 34 grams of halogen salts consisting of chloride 2.137 Gm, bromide 0.58 Gm, iodide 0.00039 Gm, fluoride 0.00028 Gm

The isotonic solution contains in each 100 cc approximately 29 grains of the halogen salts. The formula is magnesium chloride 1.82%, bromide 0.04% and fluoride 0.0018% in sterile distilled water. Halmagon preparations are suggested for the correction of general and specific conditions due to a deficient magnesium supply in the diet. They are recommended for the treatment of asthenia, lack of tone, hypothyroidism, hypoadrenia and insomnia. One to three tablets dissolved in cold or tepid water are to be taken without food on arising in the morning. A course extending over 2 months is suggested. Intensive dosage can be given by intramuscular injection of the emulsion. It should be injected deeply, and causes no local irritation. For post operative cases and patients confined to bed large doses may be given as halmagon isotonic rectal solution. This is supplied in containers which only need to be attached to a rectal tube. Halmagon tablets are issued in boxes of 4 tubes each containing 15 tablets of 7 grains sufficient for 4 weeks' administration. The emulsion is issued in boxes of six 5 cc ampuls. Halmagon isotonic solution is supplied in 100 cc, 250-cc and 500 cc containers—*Quart J Pharm Pharmacol*, 8 (1935), 159

(S W G)

Herbitten (Apotheker Wagner and Goedike Pharm Fabrik, Salzwedel) are tablets containing caffeine (0.05 Gm), phenacetin (0.15 Gm), amidopyrazolone (0.15 Gm) and antipyrine (0.15 Gm). It is used for grippe, headache, migraine and rheumatism—*Pharm Zentralh* 76 (1935), 181

(E V S)

Hepatrat Ampuls (Nordmark Werke Hamburg) A liver extract, put up in packages of 3 and 10 ampuls containing 3.30 cc—*Pharm Presse* 40 (1935), 104

(M F W D)

Hepatrat Liquid, Sweetened (Nordmark Werke Hamburg) is a liver extract in combination with a sugar solution, put up in 60-, 100 and 500 cc containers—*Pharm Presse*, 40 (1935), 104

(M F W D)

Hovaletten, forte (Chemische Fabrik J. Blaes and Co. A. G. Munchen) is a white tablet exhibiting a sedative and mild hypnotic action similar to Hovaletten Hops and Valerian. The action is intensified due to the addition of 0.01 Gm of phenylethylbarbituric acid and 0.05 Gm of phenacetin per tablet—*Pharm Zentralh* 76 (1935) 105

(E V S)

Hydronal (Bayer, I. G. Farbenindustrie A. G. Leverkusen a. Rh.) a specially prepared aluminum hydroxide in tablet form is used as an antacid against hyperacidity, for gastritis, heartburn, gastric ulcers and gastric pains—*Pharm Zentralh* 76 (1935) 215

(E V S)

Iscapral (Bayer I. G. Farbenindustrie A. G., Leverkusen a. Rh.) are tablets containing in each 0.06 Gm of prominal, 0.5 Gm of theobromine and 0.075 Gm of potassium iodide triethanolamine. It is used as a spasmolytic and vasoregulator for heart and vascular pains of angina pectoris, arteriosclerosis, etc—*Pharm Zentralh*, 76 (1935) 215

(E V S)

Jocapral (I. G. Bayer, Elberfeld) is a combination of 0.5 Gm theobromine, 0.06 Gm prominal and 0.075 Gm iodocalciumtriethanolamine in tablet form. It is an antispasmodic and vasoregulator in heart disease and diseases of the blood vessels. It gradually reduces the blood pressure and is therefore employed in angina pectoris, arteriosclerosis, vasoneurosis, etc. It is given in doses of $\frac{1}{2}$ to 1 tablet three times a day—*Pharm Weekblad*, 72 (1935), 568

(E H W)

Katamenol-Dragees (Apogepha Fabrik chem.-pharm. Preparate Dr. Starke and Max Bering G. m. b. H., Dresden A. 19) a tablet containing thyroid, ovarian substance and theobromine, is used for neurasthenia and disturbances of the menopause—*Pharm Zentralh* 76 (1935), 215

(E V S)

Larostidin is a 4% sterile isotonic solution of L-histidine monohydrochloride. It is suggested as reliable and safe for the treatment of gastric and duodenal ulcers. The treatment consists of a daily injection either intramuscular or subcutaneous of one 5 cc ampul of Larostidin for a period of 3 weeks. After 4 to 5 injections, pain disappears, nausea, vomiting and hyperacidity are relieved and after 10 days a normal diet becomes permissible. It is claimed that 70% to 80% of the cases treated gave good results. Larostidin is supplied in boxes of 6 and 25 ampuls of 5 cc—*Quart J Pharm Pharmacol*, 8 (1935), 160

(S W G)

Leciminz (C. G. Stettner, München) pastilles are composed of refined sugar (97 parts) lecithin (2.5 parts), peppermint oil, spearmint oil, ginger oil, starch and tragacanth. They are used to strengthen the nervous system—*Pharm Zentralh* 76 (1935) 181

(E V S)

Ludozan (Schering Corporation, Bloomfield, N. J.) is synthetic aluminum sodium silicate containing about 12% of sodium silicate. The product is also made under the name of "Ludozan with Belladonna" and contains 0.5% extract of belladonna. It is used as an antacid and in gastric

or duodenal ulceration It is supplied in cans containing 21 individual prescription envelopes of $\frac{1}{10}$ of an ounce each —*Drug Circ*, 79 (May 1935), 29 (T G W)

Luemed-Tablets (Dr R C Müller & Co, Berlin Pankow), an antisyphilitic, are effervescent tablets containing potassium dichromate (0.06 Gm), potassium nitrate and magnesium superoxide —*Pharm Zentralh*, 76 (1935), 215 (E V S)

Maltine with Spleenmarrow and Iron (Maltine Co, New York, N Y) Each fluidounce contains spleenmarrow concentrate, 10 minims, iron and ammonium citrate, 10 grains, copper, trace, maltine (fortified with a cod liver oil concentrate), *q s*, containing vitamins A, B, D and G It is indicated in the treatment of anemia and general debility It is supplied in 12 ounce bottles —*Drug Circ*, 79 (May 1935), 29 (T G W)

Neiso-Lysate (Eli Lilly & Co, Indianapolis, Ind) is a solution of gonococcus proteins which have been put into solution by the action of bacteriophage It is used for the treatment of gonorrheal infections and is supplied in 5 cc and 20 cc rubber stoppered vials —*Drug Circ*, 79 (May 1935), 28 (T G W)

New Remedies A review of new remedies for 1934 in which the important factors discussed are chemical structure, physiological properties and recent changes in nomenclature The following are the items reviewed

Isalon (Wiernik u Co, Berlin) is 1-phenyl-2 (methyl [diethyl aminoethyl]—aminopropane

1-ol It is said to be one-half as toxic as ephedrine and free from side actions

Dermarodol (Rosenberg, Freiburg Br) is a depressor drug, supposedly the sulphocyanate derivative of acetyl trimethylcolamine or a mixture of some sulphocyanate with acetylcholine

Dyocid (Schumann, Berlin Neuköln) is a mixture of theobromine calcium salicylate and digitalis leaves, containing also rubidium iodide It is to be used in cardiac and vascular conditions

Eurocan (Interpharma G m b H, Prag) is a 25 per cent solution of pyridine β carboxylic acid diethylamide,

recommended for respiratory and circulatory disorders

Spascul and Astmocut (Dr Lutze u Co, Berlin) are ointments of pituitary extract made from a base of wool fat into which has been incorporated 10 per cent of alcohol

Emphysemon (Ysatfabrik, Wernigerode) is a protein-free extract of kidney parenchyma, to be given intra muscularly or subcutaneously in bronchial asthma and emphysema To it is attributed a specific action on the reticulo endothelium of the lungs and bronchi

Pelein (Schering-Kahlbaum) is a bacterial vaccine originating from 60 different organisms and used against whooping cough

Hellisen (I G) is a mixed pollen extract representing 16 common European plants, used for the treatment of hay fever

Expectal (Koln Mulheim) is an expectorant, containing potassium sulphoguanicolate, extract of thyme and dipropylbarbituric acid codeine

Larostidin (Hoffman-La Roche) is an isotonic solution of 1-bistidine hydrochloride for intramuscular or subcutaneous injection in the treatment of gastro intestinal ulcers

Citro pepsin (Promonta-Werke, Hamburg) is a combination of pepsin and citric acid in the form of tablets One tablet converts 10 Gm of albumin to peptones and albumoses within three hours

Mucilekt (Nordmark-Werken, Hamburg) is a mixture of mucin, vegetable proteins and protein constituents of the blood, used in the treatment of hyperacidity, heartburn and ulcers

Euzynorm (Nordmark Werken, Hamburg) is a biological preparation, stabilized with hydrochloric acid, said to represent the total stomach enzymes

Enterofagos (Laboratoriums für medizinische Chemie und angewandte Biologie Berlin Greenwald) is presumably a mixture of polyvalent bacteriophages. It is intended for use against intestinal infections

Alloton (J. D. Riedel de Haen, Berlin) is a combination of volatile oil from garlic with desoxycholic acid, in crystalline form, which is stable in the stomach, but decomposed by the alkaline intestinal juice. It is recommended for the treatment of arterio sclerosis and as an anthelmintic and intestinal antispasmodic

Oxyaskarin (Dr. Brandt u. Co., Halle) is an anthelmintic, the active constituent of which is aluminum santoninate

Varicacid (Gehe u. Co., Dresden) is an aqueous solution of the sodium salts of certain highly unsaturated fatty acids found in cod liver oil, intended for hypodermic use in the treatment of hemangiomas and hemorrhoids

Proviron and *Androfort* (Schering) are preparations containing the male sex hormone, isolated recently by Butenandt

Proluton (Schering-Kahlbaum), *Lutren* (I. G.) and *Progestin* (Degewop) are preparations of the corpus luteum hormone

Uterstonon (Promonta) is a glandular product made from the uterus of mature cattle

Oestrurazol (Deutsche Gesellschaft für Pharmazie und Kosmetik, Berlin) is a form of combined ovarian and follicular hormones, said to be active when given orally

Profecundin (A. Richter, Budapest) is a preparation of vitamin E for the prevention of habitual abortion

Nafisal Ovula (Zimmer u. Co., Frankfurt a. M.) The ovula contain octylhydrocupreic acid hydrochloride and are used to combat the ichor of uterine cancer

Flavadin (Curta, Berlin-Brandenburg) is designated as a mixture of 3,6-diamino-10-methylacridinium glycolyl-aminophenylarsinic acid

and Trypaflavine. It is used in the treatment of cervical gonorrhea of women

Sigmagan (Max. Queisner, Charlottenburg) is a urological remedy alleged to have the formula $C_{228}H_{227}O_{117}Na_{76}Ag$ with a molecular weight of 8969, corresponding to a silver content of 1.2 per cent. The formula appears to be in error

Profundol (Promonta) is described as a three phase hypnotic, employing for the first phase bromdiethylacetylcarbamide citrate, for the second phase allyl sec-butyl barbituric acid, for the third phase, the same barbiturate mixed with designated fatty acids to inhibit absorption in the stomach

Eunarcon (J. D. Riedel de Haen) is a 10 per cent solution of the sodium salt of isopropyl β -bromo allyl-N-methyl barbituric acid, having the formula

In structure, this hypnotic is closely related to Evipan sodium. It is said to offer a wide margin of therapeutic safety and to induce sleep lasting from twenty-five minutes to two hours.

Rectidon (J. D. Riedel de Haen) is the sodium salt of β bromo allyl sec amyl barbituric acid, intended for rectal administration as a hypnotic.

Alloform (Curta, Berlin) is a preparation of aluminum containing 45 per cent of water-soluble aluminum oxide. With water it affords a stable colloidal dispersion which may be used in place of aluminum acetate solutions. It is prepared by the action of ethylene oxide on a solution of aluminum chloride.

Katalyn Silber (Schering Kahlbaum) is a colloidal form of silver, adsorbed on a ceramic powder, recommended for angina.

Simant (Verbandstoffindustrie A. G., Berlin) is said to contain silver manganite to which is assigned the formula $\text{Ag}_2\text{O} \cdot 2\text{MnO}_2$. It is supposedly unaffected by albumin and hydrogen sulphide and is marketed in the form of solution ointments and bandages.

Argoflavin (I. G.) is a complex silver salt of 3,6 diamino 10 methylacridinium lactate, containing 20 per cent of silver. It is usually given intravenously for different forms of septic infection. The argoflavin component has the formula

Dulcargan (Dr. Wüster, Walldorf bei Frankfurt) is silver tetraborate $\text{Ag}_2\text{B}_4\text{O}_6$ containing 58.1 per cent silver. Being non irritant it is recommended for infections of the eye.

Neo Olesan (I. G.) is a 10 per cent solution in oil of the bismuth salt of dimethyl endo methylene hexahydrobenzoic acid $(\text{C}_{10}\text{H}_{16}\text{O})\text{Bi}$. It may be injected without pain in all stages of syphilis.

Lecibis (Dr. R. und Dr. O. Weil, Frankfurt) is the oil soluble bismuth salt of tricamphocarboxylic acid, stabilized by means of lecithin. Its formula is given as

It is intended for intramuscular administration.

Bismutrol (Nordmarkwerke) is described as a bismuth salt stabilized by means of liver colloids. It is said to be effective as an antiluetic when given orally.

Omnival (Ifah, Hamburg) is a polyvalent vaccine, representing coli streptococci, staphylococci and gonococci, suitable for intravenous injection against gonorrhea, syphilis, etc.

Citrosulf (Nordmarkwerke, Hamburg) is a molecular compound of pyramidon and quinethiosulphate, containing also calcium, phosphorus and pentose nucleotide. It is to be used as an antipyretic.

Saridon (Hoffman La Roche) is an antipyretic containing phenacetin, allylisopropylurea, sedormid, caffeine and isopropylantipyrene.

Calmurat Salbe (Dr. Truttwein, Dresden) is a dermatological ointment containing 9 per cent of uranium and 7 per cent of bromine.

Dermazym (J. Blaas and Co., München) is a form of freshly prepared brewer's yeast without added preservative. It combines with water-soluble medicinal agents and may be emulsified with 50 per cent of fats and with tar or balsam.

Vulnovitan (Gedeon Richter, Budapest) is a solution of vitamin A in sterile paraffin oil or an ointment thereof for application to infected and post operative wounds or other purulent skin disorders.

Antipiol-Salbe (Laboratorium für medizinische Chemie und angewandte Biologie, Berlin) is a sterile, polyvalent, immunizing bacterial filtrate representing staphylococci, streptococci and pyocyaneus

Aldifen (Biochemischen Laboratoriums, Locarno) is dinitrophenol in the form of dragees

Pernaemyl and *Pernaemyl forte* (Degewop) are protein free liver extracts intended for parenteral injection

Cabion (Merck) Cantantabletten (I G) and Redoxantabletten (Hoffmann-La Roche) are tablets of ascorbic acid (vitamin C)

Chromoson (Curta Berlin) is a solution of methylene blue-glucose, to be given intravenously in doses of 10 to 20 cc in cases of carbon monoxide and cyanide poisoning—*C A ROJAHN Arch Pharm* 273 (1935), 177 (L L M)

Noctusan (Homoopathische Centralapotheke gegr von Prof Dr Mauch, Goppingen) is prepared from tinctures and homeopathic dilutions of oats passiflora, chamomile coffee pulsatilla nux vomica, ignatia and cypripedium It is used as a soporific and nerve anodyne—*Pharm Zentralh* 76 (1935) 215 (E V S)

Octinum-Suppositories (Fa Knoll A G, Ludwigshafen) contains in each 0.25 Gm *Octinum oleumicum* and cocoa butter, put up in packages of 5—*Pharm Presse*, 40 (1935) 105 (M F W D)

Pankresaletten (Dr Richard Weiss, Berlin) contain the hormone found in the pancreas with the carbonic acid salt of dekamethylenediguanidine The carbonic acid salt is soluble with difficulty in the gastric juice but is easily soluble in the intestinal fluid This condition prevents digestive disturbances Pankresaletten serve in the oral treatment of diabetes—*Pharm Weekblad*, 72 (1935), 568 (E H W)

Paradies-Salbe (Hof Apotheke Baumer & Lang, Erlangen) is an ointment containing menthol methyl salicylate salicylic acid, chloroform arnica *Rhus toxicodendron*, belladonna and hyoscyamus It is used for muscular and articular aches, gout and rheumatism—*Pharm Zentralh* 76 (1935) 216 (E V S)

Paverrysatum-Burger (J Burger Wernigerode) is prepared from *Fruct Papaveris immaturum*, sold in 15-cc vials—*Pharm Presse*, 40 (1935) 105 (M F W D)

Pentnucleotide (formerly known as nucleotide K 96) is a solution of the sodium salts of pentose nucleotides prepared for intramuscular use It is apparently a stable material, but should be stored away from light at room temperature The preparation should not be used if it shows a precipitate or turbidity It is recommended for treatment of agranulocytic angina infections with leucopenia benzol poisoning and infectious conditions such as pneumonia which are rendered more grave by a complicating leucopenia The dose is one vial (10 cc) injected intramuscularly twice a day until the white blood cell count has been normal for at least 3 days In desperate cases 20 cc may be injected twice daily for 4 days If reactions occur it may be administered in divided doses intramuscularly the site being previously anesthetized with novocaine and adrenaline—*Quart J Pharm Pharmacol*, 8 (1935) 160 (S W G)

Peroxaan (Naarden Chemical Factory) is a 10% (by volume) solution of hydrogen peroxide appearing on the market under this name in bottles of 55 cc capacity—*Pharm Weekblad*, 72 (1935), 568 (E H W)

Phenochan Salve (Pharma G m b H Aussig) contains 10% glycerinate phenylethylchonic, phenyl salicylate menthol etc, packaged in tins and tubes containing 30 Gm—*Pharm Presse*, 40 (1935), 104 (M F W D)

Proliferol (Ulmer Pharmacal Co Minneapolis Minn) A solution of tannic acid thy mol and benzyl alcohol in an alcoholic distillate produced from a combination of tinctures of organic drugs It stimulates the development of fibrous tissue cells and is used in the injection treatment of hernia It is supplied in 60 cc rubber capped vials—*Drug Circ* 79 (April 1935) 30 (T G W)

Proplasmin-Hautsalbe (Chem pharm Institut Schuren, Berlin Friedenau) contains in an easily absorbable ointment base, precipitated sulphur camphor bismuth subnitrate zinc oxide lanolin glycerin, liquid paraffin—*Pharm Zentralh*, 76 (1935) 216 (E V S)

Psorimed (Chem Fabrik Dr Aug Wolff Bielefeld) an amber colored liniment, contains in a fat free mixture coal tar, elementary sulphur, salicylic acid and dioxyanthranol It occurs in two strengths, and is used for scaly skin eruptions—*Pharm Zentralh*, 76 (1935) 106 (E V S)

Pyrethrum Ointment (Upshur Smith Co, Minneapolis, Minn) is prepared from *Pyrethrum* (*chrysanthemum*) *cinerariæfolium* or other species and an absorbent fatty base. One hundred Gm of ointment contains 0.75% pyrethrins. Its use in scabies has proved to be as effective as sulphur without causing irritation or dermatitis. It is supplied in amber jars containing 100 Gm—*Drug Circ*, 79 (May 1935), 28 (T G W)

Resyl (Ciba Company, Inc, New York, N Y) A glyceco guaiaecol preparation in syrupy form containing 0.08 Gm of guaiaecol per dram. It is used as a non irritating expectorant and antiseptic, in cases of laryngitis, bronchitis and other pulmonary affections. It is supplied in 4-oz bottles—*Drug Circ*, 79 (April 1935), 30 (T G W)

Rogerma (Laboratoires du Rogerma, M. Mahieu, Lens) is an antiseptic liquid for wound treatment containing 20 Gm of sodium tetraborate, 4 Gm of dioxybenzol, 20 Gm of boric acid, 1 Gm of salicylic acid, 0.1 Gm para isopropenylmetacresol, 0.33 Gm *Erythroxylon Coca* and 5 Gm of plant extractive—*Pharm Weekblad*, 72 (1935), 568 (E H W)

Sagradol contains mineral oil and caseara sagrada in the form of a fine emulsion. It also contains aromatics but no sugar, alcohol, narcotics or phenolphthalein. Sagradol is offered as a regulative tonic laxative suitable for the treatment of chronic constipation and associated disorders. For adults the dose is a dessertspoonful twice to four times daily, the dose for children is smaller according to age. Sagradol is supplied in bottles of 7 and 15 fluidounces—*Quart J Pharm Pharmacol*, 8 (1935), 160 (S W G)

Sedozym (Chem Fabrik J. Blaes and Co. A G, München) is a dried granular yeast preparation containing 50% of bromides as the sodium and potassium salts. It is used as a sedative—*Pharm Zentralh*, 76 (1935), 106 (E V S)

Sodium Formaldehyde Sulphoxylate (Winthrop Chemical Co, Inc, New York, N Y) A powerful reducing agent and is indicated in the treatment of mercurial poisoning. It is supplied in boxes of two 10 Gm ampuls—*Drug Circ*, 79 (May 1935), 28 (T G W)

Specialties—Newly Registered There are listed 85 pharmaceutical specialties registered in the months of March and April 1935, giving the manufacturer and agent, forms in which they are sold and a brief statement of their composition—*Pharm Presse*, 40 (1935), 175 (M F W D)

Staphylococcus Toxoid Immunization with staphylococcus toxoid has been used recently as a combined method of prophylaxis against and treatment of, chronic infections. Two preparations are issued: staphylococcus toxoid A—for active immunization (1/10 dilution) and staphylococcus B—for active immunization (undiluted toxoid) each in 1 cc containers—*Quart J Pharm Pharmacol*, 8 (1935), 160 (S W G)

Stomachysatum-Bürger (J. Bürger, Wernigerode) is a preparation made from *Artemisia absinthii*, *Achillea millefol*, *Guaphal aren*, *Rheum palmat*, sold in 15 cc vials—*Pharm Presse*, 40 (1935), 105 (M F W D)

Syncor-Suppositories (Ta Syngala, G m b H, Vienna, 16th dist) contain Syncor fluid (equivalent to 0.10 Gm digitalis leaves) and cocoa butter, put up in packages of 5 and 10—*Pharm Presse*, 40 (1935), 105 (M F W D)

Theobromine-Calcium Calcium Salicylate Pills (Dr. Kronik and Ph. Mr. Edels, Vienna, 7th dist) Each contains 0.50 Gm theobromine calcium calcium salicylate, 10 to a package—*Pharm Presse*, 40 (1935), 105 (M F W D)

Tussedat Drops are prepared in two strengths. The simple cough-drops contain extract of *Cassanea vesca*, *drosera*, *primula* and *thyme*, benzoic acid, bromides and ephedrine (0.35%). The stronger form contains the same ingredients except that the ephedrine is substituted by 0.8% ethylmorphine. The indications are all cough causing afflictions of the respiratory organs and the dose is 25 drops 3 or 4 times a day in water—*Pharm Ztg*, 80 (1935), 381 (G E C)

Typhoral, Lilly (Eli Lilly & Co, Indianapolis Ind) Each pulvule contains 10 billion heat-killed typhoid bacilli, triturated with a matrix of starch. It is used as an oral immunization against typhoid fever. Three pulvules constitute a complete immunization, a pulvule containing 1 1/2 gr of ox bile is given with the first dose. The time for the appearance of antibodies is 4 to 6 weeks after the completion of the course. The treatment should be repeated in the spring of each year. It is supplied in a single immunization package containing 3 red pulvules and 1 green pulvule (ox bile) and in boxes of 10 immunization packages—*Drug Circ*, 79 (April 1935), 31 (T G W)

Uroselectan-B-Ampuls (Schering-Kahlbaum A G, Berlin) contain 1.75 Gm of the sodium salt of *N*-methyliduochoelidan acid in 5 cc, one 5 cc ampul to the package—*Pharm Presse*, 40 (1935), 105 (M F W D)

Vaginal Catarrh Powder-Twega (Twega, G m b H, Vienna, 3rd dist) contains boric acid zinc sulphate, lycopodium and pyoktanin, put up in packages of 10 Gm—*Pharm Presse* 40 (1935), 105 (M F W D)

Vionase tablets contain in each, dried yeast 2.5 grains, exsiccated ferrous sulphate 2.73 grains, manganese hypophosphite, 0.03 grains, copper sulphate 0.03 grains, with excipient. It is indicated for the treatment of anemia, neurasthenia, debility in pregnancy and lactation and as an adjuvant to liver therapy. The dose is one tablet three times a day. Vionase tablets are supplied in bottles of 30, 100 and 500—*Quart J Pharm Pharmacol*, 8 (1935) 160 (S W G)

Vitamin Capsules, "Maltine" (The Maltine Co, New York, N Y) are capsules containing halibut liver oil standardized with other fish liver oil, with added natural vitamin D and dicalcium phosphate. The latter is an efficient reinforcement of halibut liver oil. Each capsule contains not less than 9414 vitamin A units—942 vitamin D units and is equivalent in vitamin A and D content to not less than three teaspoonfuls of cod liver oil. Each capsule contains 2 grains of dicalcium phosphate. It is indicated in dietary deficiency, particularly as regards vitamins A and D and calcium and phosphorus. It is supplied in boxes of 30 four-minum capsules—*Drug Circ*, 79 (April 1935) 31 (T G W)

Weiche Wiener Eisenpillen (Hof Apotheke Baumer & Lang Erlangen) are pills containing a reduced iron activated with organic copper. It is used for anemias—*Pharm Zentralh*, 76 (1935) 181 (E V S)

BACTERIOLOGY

Antumeningococcal Serum—A Method for Titrating the Protective Action of Mice were infected by the use of a 6% mucin suspension buffered at pH 7.4. Cultures grown on 10% rabbit's blood pneumococcus agar for 14 to 18 hours were made up to a standard of 2 billions per cc. Dilutions with mucin were injected intraperitoneally into suitable strains. For test of antibodies a dilution of the serum was injected 30 minutes previously. Tests on unselected mice are not satisfactory—GEOFFREY RAKE *Proc Soc Exptl Biol Med*, 32 (1935) 1175 (A E M)

Antistreptococcal Serum. The evidence obtained in puerperal fever causes suggests that such administration may sometimes have an unfavorable effect upon puerperal infections by hemolytic streptococci, and this impression is to some extent supported by the evidence of animal experiments. Although sera have been produced which would protect animals against infection by streptococci of artificially enhanced virulence, there is no satisfactory evidence that a serum has ever been produced which would afford more than very slight protection against hemolytic streptococci freshly isolated from acute human infections. Similarly there is no evidence that any antistreptococcal serum has ever exerted a curative effect in animals infected by such hemolytic streptococci freshly isolated from human infections. Until our knowledge of immunization against the hemolytic streptococci has progressed further it would seem desirable to discontinue the use of antistreptococcal sera in the treatment of puerperal fever and "surgical sepsis"—L COLEBROOK *Lancet* 228 (1935), 1085 (W H H)

Antityphoid Sera—Virulence Tests for Typhoid Bacilli and Antibody Relationships in Intracerebral injection of mice with typhoid bacilli combined with intraperitoneal injection of antisera is suggested for measuring the protective value of sera against typhoid bacilli and also for testing the relative virulence of typhoid bacilli strains—J NORTON and J DINGLE *Am J Pub Health* 25 (1935), 609 (A H B)

Bacteria in Water Samples—Effect of Temperature of Storage on The number of viable organisms present in water after storage for 48 hours at 0–7° changes only slightly. The ability to ferment lactose is not inhibited at low temperatures—FRED W TANNER and DORIS L SCHNEIDER *Proc Soc Exptl Biol Med* 32 (1935) 960 (A E M)

Bacteriophage—Nature of Formalin Inactivation of A staphylococcus bacteriophage was inactivated by 0.018% of formaldehyde. Diluting with 20–100 parts of water releases the bacteriophage again at a pH of 6 to 6.6 and 37°. The reactivation is completed only after 10 to 15 days—E W SCHULTZ and L P GEBHARDT *Proc Soc Exptl Biol Med* 32 (1935) 1111 (A E M)

Brilliant Green Value of, as a Local Antiseptic Even in dilutions of 1-200 000, brilliant green inhibits the growth of *Streptococcus viridans* and pneumococci. A 1% solution is used on the external skin and a 0.5% solution on the mucous membranes and for infants—J K NARAT *Zentralbl. Chir.* (1934), 49, through *Deut. Med. Wochenschr.*, 61 (1935), 72 (H R)

Brucellosis—Studies of Correlated Human and Bovine Investigation indicates that the ingestion of raw milk obtained from cows infected with contagious abortion and showing positive tests for agglutinins to *Br. abortus* in their blood is responsible for the development of similar agglutinins in the blood of some consumers. The disease manifestations are comparatively mild—R STONE and EMIL BOGEN *Am. J. Pub. Health* 25 (1935) 580 (A H B)

C Diphtheria—Isolation of Virulent and Highly Toxic Strain of A virulent strain was recently isolated by the authors which is highly toxic even in semi-synthetic medium, and which was comparable in all respects to Park Williams No. 8 strain—GEORGE F LEONARD and AUGUST HOLM *Am. J. Pharm.* 107 (1935), 174 (R F F)

Calcium Chloride Solutions—Effect of Sterilization on Solutions were prepared using calcium chloride crystals of reagent purity and calcium chloride B P which only just complied with the Pharmacopoeia limit of free alkali test. The results indicate that both Tyndallization and heating in an autoclave are suitable methods of sterilizing calcium chloride solutions, but the calcium chloride used must be of a high degree of purity to avoid the formation of deposits of calcium carbonate and other impurities such as compounds of iron and aluminum which may be present in calcium chloride meeting the specifications of the Brit. Phar.—C E COULTHARD and G F HALL *Quart. J. Pharm. Pharmacol.*, 8 (1935), 96-97 (S W G)

Cinchona Alkaloids—Pneumococcal Value of III Apocupreines (Apoquinine) The authors, on demethylation of quinine, have obtained two products (possibly geometric isomers) which they have named α - and β -apocupreines. Their dihydrochlorides are said to possess fairly high pneumococcal power *in vitro*, very low toxicity toward mice when compared with quinine, optochine or ethylapocuprine, and have a protective power similar to optochine and ethylapocuprine. The method of preparation and physical constants are given—C L BUTLER and LEONARD H CRETCHER *J. Am. Chem. Soc.*, 57 (1935), 1083 (E B S)

Diphtheria Use of Intradermal Injections of Toxin-Toxoid Mixtures Toxin-toxoid mixture seems to give promise of being a usable Schick test preparation and consists of mixtures containing diphtheria toxin diluted to Schick strength in a diluent containing purified toxoid in various concentrations studied—W E BUNNEY *Am. J. Pub. Health*, 25 (1935), 623 (A H B)

Diphtheria Toxin—Inactivation of, in vivo and in vitro by Crystalline Vitamin C (Ascorbic Acid) Vitamin C inactivates diphtheria toxin and helps to protect guinea pigs against the fatal outcome of diphtheria intoxication. Animals injected with vitamin C are temporarily rendered negative to small doses of the toxin—CLAUS W JUNGBLUT and RAYMUND L ZWEMER *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 1229 (A E M)

Germicidal Substances IV Hexylresorcinol Comparison of Resistance of Bacteria and Embryonic Tissue The highest dilution inhibiting tissue growth of phenol is 1-840, of hexylresorcinol 1-21,000. The dilutions for inhibition of *Staphylococcus aureus* are 1-65 and 1-7000 respectively. This gives for resorcinol the very favorable toxicity index 3—A J SALLE and A S LAZARUS *Proc. Soc. Exptl. Biol. Med.*, 32 (1935) 1119 (A E M)

Germicidal Substances III Mercurochrome Comparison of the Resistance of Bacteria and Embryonic Tissue to The highest dilution preventing tissue growth was found for phenol 1-840, for mercurochrome 1-10 500. The dilutions for inhibition of bacteria growth were 1-65 and 1-40. This gives a toxicity index of 12.9 for phenol and 262 for mercurochrome. Conclusion: mercurochrome rates low with reference to toxicity and germicidal power—A J SALLE and A S LAZARUS *Proc. Soc. Exptl. Biol. Med.* 32 (1935), 1057 (A E M)

Hemolytic Streptococci in Erysipelas From 52 erysipelas cases sixteen strains of hemolytic streptococci of the beta type were isolated. The results are indicative of a low protective value of erysipelas serum as it is now being prepared. Anti-scarlatinal heterogeneous serum gave greater protection than our erysipelas antiserum against the post-scarlet erysipelas strain E 111 and the strain E 109, a primary erysipelas strain—S SPICER, M F GONSHOREK and E L SPICER *J. Immunol.*, 28 (1935) 410 (A H B)

Injection of Bismuth B P—Note on the Sterilization of The author finds that injection of

bismuth can be sterilized by the autoclave process without previous sterilization of the various components of the preparation Tyndallization is not as reliable —C E COULTHARD *Quart J Pharm Pharmacol*, 8 (1935), 98-99 (S W G)

Insecticides and Fungicides The menace to public health of spray residues of lead, arsenic, fluorine and other inorganic materials on fruits and vegetables demands that insecticides of the future be organic materials, which are more toxic to insects and less toxic to mammals than are inorganic materials Such insecticides will be extracted from plants or synthesized from compounds derived from natural gas petroleum, shale oil, coal or plant products These synthetic compounds need not be so complex in structure as nicotine, rotenone and the pyrethrins for many easily made products of relatively simple constitution possess high insecticidal value Pharmacological testing of new products must accompany their insecticidal testing in order that the use of those poisonous to man and domestic animals may be avoided The field for research is immense and largely untouched —R C ROARK *Ind Eng Chem*, 27 (1935), 530 (E G V)

Measles Serum—Use of Convalescent, to Control Measles in Preparatory School In threatened outbreaks of measles convalescent measles serum in 10 cc doses with a passive immunity of from 2-5 weeks is considered a satisfactory prophylaxis —J GALLAGHER *Am J Pub Health*, 25 (1935), 595 (A H B)

Meningococcus Cultures—Viability and Virulence of Frozen and Dried Frozen and dried strains of meningococci retain their viability for many months Virulence is preserved for at least 6 weeks —GEOFFREY RAKE *Proc Soc Exptl Biol Med* 32 (1935), 975 (A E M)

Mercurials—Some Organic The authors have studied the bacteriostatic action of 21 organic mercurials in which the mercury is linked to carbon They found the mercury derivatives of more complex structure to be less effective than the mercury derivatives of hydrocarbons and phenols The four most effective in order of decreasing activity were *o* hydroxyphenylmercuric chloride, phenylmercuric nitrate, phenylmercuric acetate and phenylmercuric lactate *Staph aureus* was used The methods of preparation of mercurials are given or referred to —MERRILL C HART and HANS P ANDERSON *J Am Chem Soc*, 57 (1935) 1059 (E B S)

Poliomyelitis—Convalescent Serum in The pathogenesis of poliomyelitis, as a disease transmitted by nerve fibres and entirely neurotropic suggests the ineffectiveness of serum therapy because the antibody can never reach the virus in the central nervous system, therefore the likelihood of success with a serum is slight —M BRODIE *J Immunol* 28 (1935) 360 (A H B)

Preservatives—Notes on Some New, used in Pharmacy The author had occasion to try the methyl and propyl esters of parahydroxy benzoic acid as preservatives for a solution of tartaric acid and an infusion of Calumba The author concluded that a 1% W/V solution of tartaric acid in water may be preserved by the addition of 0.05% methylparahydroxybenzoate, or 0.01% of propylparahydroxybenzoate The Fresh Infusion of Calumba is preserved for four days by 0.15% methylparahydroxybenzoate, the propyl ester having practically no preservative effect The addition of 10% v/v of alcohol (90%) efficiently preserved Fresh Infusion of Calumba —E E NYE *Australasian J Pharm*, 16 (1935) 183 (T G W)

Prontosil—Bactericidal Value of Prontosil displayed streptococcicidal action in infected mice when given subcutaneously or perorally in concentrations up to 4% As a rule 0.02-0.1 of the tolerated dose sufficed to cure the infection while in some cases 0.002-0.01 of the tolerated dose prolonged life A good effect was also observed in chronic streptococcal infections in rabbits with swelling of the joints While not as regular and sure in its effect on staphylococci as on streptococci, this dye was capable of curing rabbits with staphylococcal infections when given intravenously, subcutaneously and orally every day There was no effect on pneumococcal or other bacterial infections The non toxicity of the drug was indicated by the fact that perorally, mice tolerated at least 500 mg per Kg without any symptoms, rabbits at least 500 mg per Kg and cats at least 200 mg per Kg Subcutaneously mice tolerated 1-2 cc of 0.25% solution or 1-2 cc of a 4% suspension of the dye per 20 Gm Rabbits could be given at least 10 cc of a 0.25% solution intravenously or subcutaneously daily for at least 14 days without any deleterious changes in the blood or urine The dye is excreted in the urine which is colored red or reddish yellow about ½ hour after peroral administration —GERHARD DOMAGK *Deut Med Wochschr*, 61 (1935), 250-253 (H R)

Psittacosis—Recent Studies on The intraperitoneal injection of mice with the suspected

material constitutes the best and safest procedure to demonstrate the presence of the virus. Material from 6 human cases showed that the lungs invariably contained the infective agent in such concentrations that the mice succumbed in from 6 to 8 days with typical lesions. The majority of psittacosis infections have occurred in people of middle age. The lower susceptibility of children is well known. California will restrict the sale and distribution to lots of parakeets which have been sampled and tested in the laboratory—K. F. MEYER, B. EDDIE and I. M. STEVENS. *Am J Pub Health*, 25 (1935), 571 (A. H. B.)

Psittacosis Virus—Growth and Development of, in Tissue Cultures In these experiments the virus was obtained from 1930 infected parrots, and the virulence maintained by passage through mice. Tissue cultures in mice spleens and tissues from chicken embryos were used successfully, and also a fluid medium containing two parts of chicken plasma, three parts of chicken embryo extract and the fluid expressed from the broken clot diluted with an equal amount of saline solution. Stained by Giemsa's stain, the virus colonies were photographed and seen to undergo five cyclogenic phases: (1) The unidentifiable, (2) Homogeneous plaques, (3) Phase of large forms, (4) Phase of intermediate forms, (5) Phase of elementary bodies. This development phase cycle of variants starts in eight hour cultures and ends at forty eight hours of growth. Occasionally motile colonies of the virus have been observed. The virus infects both epithelial cells and fibroblasts—J. O. W. BLAND and R. G. CANTI. *J Path Bact (Brit)*, 40 (1935), 231 (A. H. B.)

Staphylococcus Toxins and Antitoxins By hemolytic titrations and intracutaneous testing it was determined that certain strains of staphylococcus produce two toxins for which there are corresponding antibodies, namely, Alpha Beta antitoxins demonstrable in immunized horse serum—A. T. GLENN and MURIEL F. STEVENS. *J Path Bact (Brit)*, 40 (1935), 201 (A. H. B.)

Sterilization by Dry Heat at 150° C with Special Reference to Oils The work reported confirms the bactericidal efficiency of the Brit. Phar. process for dry heat sterilization. The necessity of taking the temperature of oils by immersion of the thermometer in oil is stressed. The heating caused loss of color in the oils, but no significant deterioration was noted—C. E. COULTHARD. *Quart J Pharm Pharmacol*, 8 (1935), 90-93 (S. W. G.)

Sterilization of Oils—Note on Results of experiments are noted. The following conclusions have been stated: 1. Even grossly contaminated oils are sterilized by heating at 150° C for one hour, it is probable that heating at 140° C for one hour under reasonable clean conditions of working in a pharmacy, would ensure sterility. 2. The prescribed method of Tyndallization may fail to sterilize contaminated oils—R. A. O'BRIEN and H. J. PARISH. *Quart J Pharm Pharmacol*, 8 (1935), 94-95 (S. W. G.)

Vitamin C and Diphtheria Toxin Vitamin C increased the resistance of guinea pigs to injections of diphtheria toxin. Mixtures of vitamin C and toxin kept in contact for one hour showed decreased toxicity. Such injections do not cause immunization—CHARLES K. GREENWALD and E. HARDE. *Proc Soc Exptl Biol Med*, 32 (1935), 1157 (A. E. M.)

BOTANY

Camphor—Maximum Yield of, Obtained from *Laurus Camphora* Autumn is the most favorable season to collect leaves of *Laurus Camphora* because they contain at this time the most camphor—A. ONISCHTCHENKO and A. CHOMENKO. *Soujet-Pharmaz. Russ. Savjetskaja Pharmacia*, 5 Nr. 6 (1934), 39-42. *Abchas. Zonale station Wilar*, through Chem. Zentr. 106 (1935), 923 (G. B.)

Eucalyptus—Physiological Forms of, as Determined by the Chemical Composition of Essential Oils and Their Influence on Botanical Nomenclature The occurrence of physiological forms in the Eucalypts is of considerable economic importance. *Eucalyptus dives*, the broad leaf peppermint, contains from 40% to 50% piperitone. In some cases the piperitone content fell far below this value, some yielding only 8% and 10% of the ketone. An observation was made of two trees growing together indistinguishable by a botanist, but each containing a different essential oil. A peppermint odor typical of *Eucalyptus dives*, was yielded by one, while in the other, an odor of cineol and terpinol was detected. It was therefore apparent that several varieties or forms of *Eucalyptus dives* existed distinguishable only by chemical means. About the same time a similar case was noticed with *Cinnamomum camphora*. The same behavior was noticed with

Eucalyptus radiata and *Eucalyptus micrantha* It is evident that the discovery of these physiological forms is going to bring about a revolutionary change in the botanical nomenclature of the Eucalypts. Over 400 species have been recorded and in view of the physiological forms which have already been observed the question arises whether the actual number of species is likely to exceed 100.—A. R. PENFOLD *Australasian J. Pharm.* 16 (1935), 168 (T. G. W.)

Nicotiana Rustica—Harvesting Time for The highest nicotine content (up to 4.93%) was found in overripe *Nicotiana rustica*, in spite of the infection frequently observed with this kind of tobacco on ripening.—S. KAMSKII *Tabachnaya Prom.* (1934), 26, through *Chem. Abstr.*, 29 (1935) 3109

Plants—The Growth-Promoting and Growth-Arresting Action of Pigments on Certain pigments exercise a great influence on the vegetative growth of plants. Given pigments especially if fluorescent may either retard or promote growth, depending upon the concentrations at which they are applied. The cause of this phenomenon is related to the photodynamic action of the pigment, and is independent of the soil salts.—J. SELLEI *Arch. Pharm.* 273 (1935), 285 (L. L. M.)

Polypodiaceæ of Pharmaceutical Interest—Anatomical Investigation of the Leaves of The following are the drugs considered: *Aspidium filix mas* (L.) Sw., *A. lobatum* Sw. or *A. aculeatum* Doll, *A. spinulosum* subsp. *dilatatum* Lam., *Athyrium filix femina* Roth, *Scolopendrium Sm.*, *Blechnum spicant* With, *Polypodium vulgare* L., *Pteridium aquilinum* Kuhn, *Asplenium ruta muraria* L., *Asplenium trichomanes* L., *Asplenium ceterach* L., and *Adiantum capillus veneris* L. Photographs and illustrations together with a key for differentiating the species are given.—E. BRAUN *Arch. Pharm.*, 273 (1935) 201 (L. L. M.)

CHEMISTRY

GENERAL AND PHYSICAL

Acacia Solutions—Physicochemical Studies on III Osmotic Pressures of Solutions of Arabic Acid and Sodium Arabate A method is outlined by which accurate osmotic pressure-concentration relationships may be obtained for systems containing a colloid as the non-diffusible component. In the case of solutions containing arabic acid and sodium arabate the equilibrium distribution of water and diffusible ions across the membrane was found independent of the size of pore and of the material of the membrane. The calculated osmotic pressure was consistently greater than the observed equilibrium pressure; the difference bearing a definite relationship to certain other variables in the system.—D. R. BRIGGS *J. Phys. Chem.* 38 (1935) 1145, through *Squibb Abstract Bull.* 8 (1935) A-494

Atomic Weights—Committee on—Fifth Report of, of the International Union of Chemistry The report covers the period September 30 1933 to September 30 1934. Reports on the following atomic weight determinations are given: carbon, nitrogen, sodium, calcium, krypton, columbium, molybdenum, iodine, cesium, tantalum, lead, radium, protactinium and the rare earths. The only change made in the table of atomic weights was columbium (niobium) from 93.3 to 92.91.—G. P. BAXTER, O. HONIGSCHMID, P. LE BEAU and R. J. MEYER *J. Am. Chem. Soc.*, 57 (1935) 787 (E. B. S.)

Denatured Salts—Contribution to the Knowledge and Determination of Denaturants of salts (rock, foundry or sea) allowable by law are mineral oil, iron oxide, powdered soap, sodium sulphate, sodium carbonate, uranin, crystal ponceau R₆, gut or rennet, brine, alum and petroleum. The choice of the denaturant is dependent upon the purpose of the salt, such as sodium carbonate for bath salts, sodium sulphate for saponification salts, and alum or petroleum for tanning of hides. Typical formulæ for the various types of denatured salts are given. The detection and determination of the denaturants are carried out according to the usual analytical methods.—JOHANNES PRESCHER *Pharm. Zentralh.* 76 (1935) 157 (E. V. S.)

INORGANIC

Hydrogen Peroxide Hydrogen peroxide was discovered by Thenard in 1818. Many attempts to combine oxygen and hydrogen directly to form hydrogen peroxide have been made using catalysts such as high pressure, electrical methods, ultraviolet light, etc., but none have given results which are of value commercially. A recent development was the use of sodium

peroxide, from sodium made by the electrolysis of common salt, and decomposed by hydrofluoric acid. The persulphuric acid process was the first successful commercial process. The potassium persulphate process consists of electrolyzing an acid solution of ammonium sulphate until it contains from 10 to 15 grains of active oxygen per liter. It is then mixed with potassium bisulphate, and potassium persulphate crystallizes out. This is mixed with a solution of sulphuric acid and heated by steam in a still. Hydrogen peroxide and water distil, condensing as 100 volume peroxide. The ammonium persulphate process is the most recent. An acid solution of ammonium sulphate is electrolyzed, with the formation of ammonium persulphate, which when distilled reacts as $(\text{NH}_4)\text{S O}_8 + \text{H SO}_4 + 2\text{H O} = (\text{NH}_4)\text{SO}_4 + 2\text{H SO}_4 + \text{H}_2\text{O}$. A small addition of phosphoric acid is made to assure the greatest stability. —E I ROSENBLUM *Australasian J Pharm*, 16 (1935), 35 (T G W)

Selenium—Distribution of, in Nature. The author has analyzed a large variety of geological materials for their selenium content and points out the economic importance of the distribution of selenium in nature, particularly in the fields of biology and agriculture. In spite of the fact that this is a rather rare element, its occurrence in amounts as small as 1 to 10 parts per million may constitute a great danger to agriculture as a toxic substance to plants and animals. Selenium is definitely poisonous and the gravity of this menace to mankind cannot be minimized. —LESTER W STROCK *Am J Pharm*, 107 (1935) 144 (R R F)

Kaolin—Pharmaceutical. The standards prescribed for kaolin are critically reviewed. Results of tests are given. Paragraph four in the monograph on Kaolin in the Belg Phar should be changed as follows: Mix intimately 3 Gm of kaolin with 30 Gm of water and 1 Gm of hydrochloric acid. Shake the mixture frequently and after 2 minutes, filter. The filtrate should not be altered by hydrogen sulphide nor colored blue immediately on addition of potassium ferrocyanide. Alkalinize with ammonia water and filter. The filtrate should not form a precipitate with ammonium oxalate or with sodium phosphate. Treat 1 Gm of kaolin with a mixture of 5 cc diluted hydrochloric acid and 5 cc of water, shake and filter. Five cc of the filtrate evaporated and dried, should give only 4 mg of residue. —MAURICE TRAMASURE *J pharm Belg*, 17 (1935) 225-228 (S W G)

ORGANIC

Alkaloids

Alkaloids—Synthesis of New Medicinal. Most benzoyl and *p* aminobenzoyl esters of alcohol bases act as local anesthetics and some basic ethers and amides have the same property, a molecular weight of about 250 appearing to give the optimum action. The tropic and mandelic esters of amino alcohols exert a mydriatic and antispasmodic action, in some the mydriatic action and in others the intestinal action predominates. Methylcarbamate esters of basic phenols exert a myotic and intestinal stimulating action. Aminoalkoxy quinoline and -acrine derivatives in which the amino group carries a basic side chain exert a toxic action on the malaria parasite. Derivatives of isoquinoline with alkoxy groups and heavy substituents have an antispasmodic effect. In many cases it is possible to deduce through which nerves, organs or tissues the action takes place and thence that the solubility relationships of the compound must result in its having an affinity for certain parts of the body. The evidence shows that papaverine acts directly on smooth muscles whereas atropine produces its effects through the parasympathetic nervous system. Usually it is not possible to explain why an alkaloid exerts a particular action rather than any other. Pharmacology and medical chemistry have produced many useful drugs if they have not succeeded in explaining their action. —J A AESCHLIMANN *J Soc Chem Ind*, 54 (1935), 135T (E G V)

Cereus Coryne—Alkaloids of. The cactus *Cereus coryne*, abundant in Cordoba (Argentina) was extracted with 96% warm alcohol acidified with acetic acid. The extract was concentrated *in vacuo*, diluted with water and again concentrated to remove the alcohol. Resins precipitated in aqueous solution. Intravenous injection of the purified extract, into chloralosed dogs, immediately increased the amplitude of respiration and produced an initial decrease in pressure followed by an increase. Section of the vagus suppressed the initial hypotension. The hypertensive activity of this 1% alkaloid extract was similar to 0.8% nicotine or 1.25% canidine iodide solution. In toads, a subcutaneous injection of 0.5 cc of the cactus extract produced marked secretion by the cutaneous glands, muscular incoordination, paralysis and cessation of respiration.

in 6 minutes From the chemical and pharmacological behavior of the extract, the active principle was believed to be a dihydroxyphenyltrimethyl ammonium derivative This base was synthesized and found to have a similar action —L RETI, R I ARNOLD and F P LUDUENA *Compt rend soc biol*, 118 (1935), 591, through *Squibb Abstract Bull*, 8 (1935), A-499

Curare Several species of *Strychnos* were tested for curare content only *S. toxifera* contained significant amount of curarine (0.2%) Chemical examination of tubocurarine yielded crystalline tubocurarine, dextrorotatory and with the empirical formula $C_{19}H_{27}O_3NCl$ an allied substance *d* bebeerine which is less potent was also obtained If the formula for tubocurarine is doubled, a product is suggested isomeric with bebeerine methochloride —H KING *Nature* 135 (1935), 469, through *Chem Abstracts*, 29 (1935), 3464

Ephedrine—Sources of During the year investigations of a number of important indigenous drugs were completed A powerful sympathomimetic alkaloid resembling ephedrine in action was discovered in *Moringa pterygosperma*, a plant commonly grown in the sub Himalayan tracts in northern India A readily available source of ephedrine has also been found in another plant, *Sida cardifolia* which not only grows wild but is cultivated in many parts of India The finding of ephedrine in these plants is significant and opens up the possibility of another source of ephedrine —J TROP *Med Hyg*, 38 (1935), 17, No 5, through *Squibb Abstract Bull*, 8 (1935), A-462

Ergometrine A brief review of the work of Moir and Dudley, and of Karasch and co workers on new ergot alkaloids —K O MOELLER *Dansk Tids Farm*, 9 (1935), 121

(C S L)

Ergot Alkaloids Ergot alkaloids may be obtained in a pure form by shaking ergot alkaloids with an aqueous solution of caustic alkali acidified with lactic acid and then with an organic solvent The two layers are separated and the alkaloids recovered from the organic solvent by evaporation and crystallization The product may be further purified by recrystallization —FIRMA E MERCK (Willi Kussner) Ger Pat 606 778, Dec 11, 1934 (Cl 12p 11 01)

(S W G)

Ergotocin Active Principle of Ergot Responsible for the Oral Effectiveness of Some Ergot Preparations on Human Uteri (A communication) The authors claim to have isolated a pure crystalline principle from ergot A yield of 0.3 mg is roughly equal to 3–4 Gm of the crude defatted ergot It is uniformly effective in oral doses of 0.3 mg and intravenous doses of 0.1 mg Its action is instantaneous and its effect lasts for three to four hours It possesses low toxicity Chemically it is a base melting with decomposition at 155° C It forms well defined salts and is not precipitated by Meyers' reagent in dilutions greater than 1 part in 7500 The method and analysis are not given —M S KHARASCH and R R LEGAULT *J Am Chem Soc*, 57 (1935) 956

(E B S)

Ipecac Root—Localization of the Alkaloids in Some textbooks state that the alkaloids are localized just outside the cambium ring in ipecac root which may be demonstrated by the use of picric acid or potassium dichromate The author however, has applied a new method and finds the alkaloids to be localized in the cortical cells near the cork The cross sections are placed in a 10% solution of potassium ferrocyanide for several minutes the alkaloids being precipitated by this reagent The excess is then washed out and the ferrocyanide combined with the alkaloids made visible by treatment with ferric chloride The alkaloidal cells become an intensive greenish blue The reaction is sharp and the cells stand out in contrast to the other cells in the tissue If the section is not too thin and is subsequently cleared with chloral hydrate a beautiful reaction results, always showing the alkaloids to be localized peripherally This microchemical result was checked by removing consecutive layers from the root with a file dialyzing the resultant powders in dilute hydrochloric acid and testing the dialyzed solutions with such alkaloidal reagents as iodine potassium iodide potassium mercuric iodide, potassium cadmium iodide potassium bismuth iodide, picric acid and potassium dichromate The author suggests that the precipitates obtained by treating sections with picric acid and potassium dichromate which were found by previous workers to occur just outside the cambium ring were due to albumin This albumin does not combine with the ferrocyanide —M WAGENAAR *Pharm Weekblad*, 72 (1935), 513

(E H W)

P'an-shua—Chemical Composition of The Chinese drug p'an shua (*Pinellia tuberifera* Ten or *P. ternata* Breit) has an anesthetic action and gives an ether extract having alkaloidal reactions

—TEN-HAN TANG and TSEI-YING TSENG *Natl Shanglung Univ Chem Lab Repts*, 3 (1934), 63, through *Chem Abstr*, 29 (1935), 3115

Phenyl Procaine—Local Anesthetics Report is made of a study of the phenyl derivatives of procaine and its analogues. Because of the comparatively greater activity and lesser toxicity of *o*-phenyl phenol over phenol it was thought that substitution of a phenyl group on the benzene nucleus of procaine would yield a product of greater potency and less toxicity. The synthesis used was the preparation of 2-carboxy 5-amino diphenyl and subsequent reaction of the sodium salt with β -diethylamino ethyl chloride. Phenyl-procaine is an active anesthetic but it precipitates upon the addition of buffers and in corneal and intradermal tests it caused irritation. Analogues of phenyl procaine were synthesized for the purpose of determining effect of increasing the size of the dialkyl amino alkyl group (III), ascertaining the effect of alkylating the amino group (IV), investigating the effect of halogenation (V), observing effect of elimination of amino group (VI). The hydrochlorides of IV and VI are too acid for testing and III and V were too inactive to warrant further investigation. A compound (VII) was found to be rather inactive and the amino group was shifted from the 5- to the 4'-position and an aqueous solution of the hydrochloride of this substance (VIII) was also inactive. Biological tests indicated that phenyl procaine is more active than cocaine hydrochloride and novocaine. Tabulation of comparative tests on guinea pigs shows this. It was also more active on the rabbits cornea but slightly irritating. The most active of the compounds is the hydrochloride of β -diethylamino ethyl 2-phenyl 4-amino benzoate.—W. BRAKER and W. G. CHRISTIANSEN *J Am Pharm Assoc*, 24 (1935), 358 (Z M C)

Strychnine Benzoates—Solubility of Some The solubilities in water at 20°, 30°, 40°, 50°, 60°, 75° and 95° have been determined for the following strychnine salts: benzoate, *o*-, *m*- and *p*-chloro-, -bromo-, -iodo-, -nitro-, hydroxy-, methyl- and -aminobenzoates, 3,5- and 2,4-dinitrobenzoates, 2,4,6-trinitrobenzoate, and 5-iodo-, 3,5-dinitro- and diiodosalicylates. A table lists the results.—CHARLES POE, JOHN F. SUCHY and GEORGE L. BAKER *J Phys Chem*, 39 (1935), 239, through *Squibb Abstract Bull*, 8 (1935), A 557

Valerian Alkaloids Presence of α -Pyrrol Methyl Ketone in Stabilized Official Valerian. α -Pyrrol methyl ketone is reported for the first time to be present in plants, having been found to constitute an active principle of valerian. Experiments were performed on industrial residues obtained from fresh rhizomes and roots of valerian stabilized by alcohol. The filtrate obtained after the distillation of the alcohol was washed with ether and the resulting acid residue neutralized by a 25% aqueous solution of sodium carbonate. The uncombined material was extracted with ether, the ether evaporated off and the crude semi liquid mass left saponified with 10% alcoholic potassium hydroxide. The solution obtained was concentrated, taken up with water and extracted with ether. The above ketone was isolated from this extract by distillation, the distillate going over between 60° and 125° under 0.75 mm pressure, being rectified to a slightly yellow-colored liquid, b_D^{25} 68–73°, which crystallized after standing for 13 hours on ice. Fractional crystallization from boiling petroleum ether yielded white, silky needles, m 90°, soluble in water and the usual organic solvents.—E. CRONGA *Compt rend soc biol*, 200 (1935), 780, through *Squibb Abstract Bull*, 8 (1935), A-482

Veratrine Alkaloids Parts I and II. Veratridine (I) isolated from commercial veratrine by the formation of the nitrate salt, and purified by reprecipitation as the nitrate and precipitation as the sulphate, softened, when heated, over the range 160–180° and had $[\alpha]_D^{25} +8.0^\circ$ (4% solution in 96% alcohol). After drying at 110° in a high vacuum, I lost its adsorbed water and in addition decomposed slightly, giving off water. I was obtained in a 21% yield. Cevadine, m p 199–201°, was obtained from the filtrate after precipitation of I as the nitrate. Alkaline hydrolysis of I yielded slightly less than the theoretical amount of cevine (II) and the mother liquor yielded veratric acid, m p 179°. Dehydrogenation of II with selenium gave cevanthridine (III), m p 208° in a yield of 100 mg from 5 Gm of II. The hydrochloride of III melted at 245° and the picrate decomposed at 230–240°. The methiodide melted at 254–256° with decomposition. At higher temperature the yield of III is diminished and a crystalline hydrocarbon isolated.—B. K. BLOUNT *J Chem Soc* (Feb 1935), 122, through *Squibb Abstract Bull*, 8 (1935), A 559

Wei-ling-sein—Studies on The Chinese drug wei ling sein, identified as *Clematis angustifolia* Jacq, functions as an anesthetic and contains an unidentified alkaloid.—TEN-HAN TANG and CU HSIANG CHAO *Natl Shanglung Univ Chem Lab Repts*, 3 (1934), 19, through *Chem Abstr*, 29 (1935), 3115

Essential Oils and Related Products

Achillea Millefolium Linnè—Volatile Oil of Although L. F. Bley has been given credit for first producing this volatile oil in 1828 it now appears that one or several prior workers undoubtedly obtained this volatile oil more than a century before the publication of Bley's work. Work carried on by the author indicates that the optical rotation value given by Haensel (*Berichte*, 4 (1901), 25) is in error. The true value, as well as figures for specific gravity and refractive index are given.—R. L. McMURRAY *Am J Pharm* 107 (1935), 33 (R. R. F.)

Artemisia Rigida (Nutt.) Gray—Oils of The authors found that the blooming tops of this plant yielded 0.56% of a volatile oil, of which 27.92% were stereoptene and 72.08% were oleoptene at 15° C. The oleoptene was amber to yellowish in color, becoming deeper colored with age, odor pungent and somewhat camphoraceous, taste warm, persistent and aromatic, feel turpentine like. It was acid to litmus paper. It was miscible with absolute alcohol, 95% alcohol, acetone, glacial acetic acid, chloroform, ether and petroleum ether, immiscible with carbon disulphide. The following constants were obtained on the oleoptene: Specific Gravity, 25°/25° C 0.9367, Optical Rotation 100 mm tube 25° C, -15.68°, Specific Rotation 25° C -16.75° Refractive Index 25° C 1.4674, Acid Value 3.63, Ester Value, 19.46, Saponification Value 23.09. After the removal of the volatile oil by steam distillation, the material was further treated and a fatty oil amounting to 1.88% was obtained. The fatty oil was viscous and very dark green in color. The following constants were determined for this fatty oil of *Artemisia Rigida* (Nutt.) Gray: Specific Gravity 40°/40° C 0.9945, Refractive Index 40° C, 1.4968, Acid Value 36.68, Ester Value 91.64, Saponification Value 128.32, Iodine Value, 58.71.—G. NORRIN and R. L. McMURRAY *Am J Pharm* 107 (1935), 177 (R. R. F.)

Camphor—Production of, from *Ocimum Canum* The Japanese *Cinnamomum camphora* from Formosa and the German synthetic camphor have been the only sources of supply of camphor for Russia. *Ocimum canum* was first successfully cultivated by the French under the direction of E. Scharabots in 1930. *O. canum* exists in two forms which cannot be differentiated morphologically, but which yield two differently constituted oils. One variety contains methyl cinnamyl ether ($C_{10}H_{16}O_2$) while the other contains camphor ($C_{10}H_{16}O$). Yields of from 35 to 50% of camphor have been obtained from the camphor containing oil of *O. canum*. In Krasnodar, Russia, *O. canum* can be cultivated as an annual plant. This Krasnodar variety contains on an average 2.48% of ethereal oil from which 44.34% of camphor can be obtained by freezing. The plant requires no particular care under cultivation and yields camphor the very first year. A detailed macro and microscopic description of the plant is given. The technique of planting and cultivation is described minutely. The procedure for the extraction of the camphor is as follows: The plant is distilled with water in a still having a wide but short head. The distillate is shaken with 5% of its volume of benzene to dissolve out the camphor. The camphor is extracted from the benzene with alcohol. Since the ethereal oil solidifies very easily and stops the condenser, the distillation can be carried out without the use of a condenser. The alcoholic solution is imbedded in ice and the camphor which congeals is separated from the liquid portion by compression. The pressed material is redissolved in alcohol, filtered and the solution concentrated at 80° to 100° C. At 100° C camphor is fluid and is poured into forms from which is obtained on cooling a transparent mass. The physical properties of camphor obtained by this process are listed.—A. ROTER MEL *Pharm Ztg*, 80 (1935) 337 (G. E. C.)

Citronella Oil—Java A graph is given which presents a clear picture of the particularly unsatisfactory situation which the oil has developed, especially in the last two years. In 1933 the export expanded by about 53.5% as compared with the preceding year, while in 1934 the increase as compared with 1932 amounted to about 79.5%. The larger production results from the increased acreage under sereh grass. In this connection three tables are included which give a survey of the last five years. Other graphs and tables are given which show the countries of destinations of the shipments in the last five years.—A. F. HACCOW *Perf and Ess Oil Rec*, 26 (1935) 165 (A. C. DeD.)

Eucalyptus Oils—Development of Our Knowledge Concerning Eucalyptus oil was one of the first products exported from Australia in 1788. Joseph Bosisto, a Victorian pharmacist, played an important part in the establishment of the eucalyptus oil industry in 1852. Eucalyptus trees are mostly Australian, although some species are found in New Guinea, Timor and the Philippine Islands. Essential oils from Eucalyptus are useful commercial products and are ex-

ported from Australia to the extent of 100,000 gallons a year. There are over 350 species of this genus but less than 20 yield an oil of commercial value. The first investigation of Eucalyptus oils was made by M. Cloez in 1870 upon the oil of *Eucalyptus globulus*. This oil, known as cineol, distills at 175° C. Several other constituents, such as acetic and formic acids, butyric and isovaleric aldehydes were isolated by M. R. Voiry in 1888. R. T. Baker and H. G. Smith later showed an obtuse "feather" venation was indicative of a low yield of oil, with pinene as the principal constituent, a lateral venation with a marginal vein represented a slightly higher oil yield with cineol and pinene as constituents, while "butterfly wing" venation gave a high yield of oil with a composition of plicaudrene and piperitone.—A. R. PENFOLD *Australasian J. Pharm.*, 16 (1935), 29 (T. G. W.)

Hyptis Mutabilis—Volatile Oil of. Material for this investigation was collected in Florida and was of two types, green stemmed and red stemmed. These were studied separately. The yield of volatile oil from the above ground portion of the plant was from 0.012% to 0.02% and seemed to be identical in the two varieties. The oil has a high hydrocarbon content and the presence of sabinene and caryophyllene is indicated.—HAROLD W. WERNER *J. Am. Pharm. Assoc.*, 24 (1935), 289 (Z. M. C.)

Patchouli Oil of the Seychelles. A discussion of patchouli oil including the propagation of the plant, the harvesting, the preparation of leaves prior to distillation, the distillation and the controlling ordinances.—W. H. HODSWORTH HAINES *Perf. and Ess. Oil Rec.*, 26 (1935), 171 (A. C. DeD.)

Peppermint Oil—from Black Mint Cultivated in Southern Sweden. *Mentha piperita* var. *officinalis* forma *rubicens*, Camus plants grown under favorable conditions in southern Sweden yielded peppermint oil of satisfactory quality.—R. FORNET *Seifensieder-Ztg.* 62 (1935), 223, through *Chem. Abstracts*, 29 (1935), 3465

Violet Odor—Natural. A review of the more recent research concerning violet oil, orris oil, violet-leaf oil and violet root oil is discussed.—F. K. DONOVAN *Perf. and Ess. Oil Rec.*, 26 (1935), 93 (A. C. DeD.)

Fired Oils, Fats and Waxes

Piqui-A Fats—Component Glycerides of. The yield of fats from the whole fruits of the piqui A (*Caryocar villosum*) is about 6 to 7% mesocarp and less than 1% kernel fat. The component glycerides (weight percentages) of the original fat are given as follows (leaving out of account the very small amounts of myristic, stearic and linoleic glycerides present, or, rather, grouping the 1.8% of myristic with palmitic acid, and the similar amounts of stearic and linoleic acids with oleic acid): tripalmitin 2%, dipalmitoleins, 42%, palmitodiolens, 56%. Both α and β palmitodiolens and α and β oleodipalmitins are probably present in quantity.—T. P. HALDITCH and J. G. RIGG *J. Soc. Chem. Ind.*, 54 (1935), 109T (E. G. V.)

Glycosides, Ferments and Carbohydrates

Glycyrrhizin. The dilute alkali extracts of liquorice is treated with a magnesium or calcium salt until there is no further precipitation. Glycyrrhizin separates from the filtrate upon the addition of acid.—KANEGAHUCHI BOSEKI K. K. (Toyo Ito) *Japan Pat.*, 109,401 (Jan. 29, 1935) (S. W. G.)

Strophanthin of Strophanthus Eminii. E-strophanthin was obtained from the crushed seeds of *S. Eminii* by extraction with 90% alcohol at room temperature after previous defatting with light petroleum. The percolate was concentrated and treated with a slight excess of basic lead acetate, then filtered and the filtrate was freed from lead with hydrogen sulphide. The solution was saturated with ammonium sulphate and the sticky precipitate was extracted with alcohol. The alcoholic solution was either neutralized with sodium hydroxide and precipitated with ether or precipitated without neutralization. The product was dried at 100° C. *in vacuo*. The yield was 5-7% of the fat free seeds and was similar to that obtained from *S. kombe*. E-strophanthin is a yellowish white powder consisting of vitreous particles, and it is readily soluble in water and in 90% alcohol or dehydrated alcohol. It is almost insoluble in ether, chloroform, benzene or light petroleum. E-strophanthin may be differentiated from L-strophanthin by the color reactions given by Smelt (*Quart. J. Pharm. Pharmacol.* 6 (1935), 467). E-strophanthin contains "water of hydration" in addition to 'hygroscopic moisture' determinations giving 5.9, 3.5% of "water of

hydration" and 19.10% of 'hygroscopic moisture' A 2% aqueous solution had a pH 4.2, but was neutral on dilution to 0.1% It complies with the U S Phar test for reducing sugars in strophanthin, and was found to have a specific rotation $[\alpha]_D =$ about $+10^\circ$ (c in dehydrated alcohol = 2) E-strophanthin was examined chemically by Jacobs and Bigelow (*J Biol Chem* 99 (1933) 521, 101 (1933), 697) and was found to be similar in type to that of the official L-strophanthin, but the two are not identical E strophanthin has a cardiotonic activity equal to that of the British Standard Strophanthin—I D LAMB and S SMITH *Quart J Pharm Pharma col*, 8 (1935), 71-74 (S W G)

Other Plant Principles

Cimicifuga Racemosa—Constituents of the Rhizome of From the rhizome were isolated a very soluble acid saponin, a glucoside tannin containing a phlobaphene, another water soluble glucoside and a glucoside insoluble in water but soluble in alcohol Only the last named has a cardiotoxic action in dogs The lethal dose is 20-30 mg/Kg when given intravenously—F MERCIER and J BALANSAND *Compt rend soc biol*, 118 (1935), 79, through *Chem Abstr*, 29 (1935), 3111

Digger Pine (Pinus Sabinana)—Non-Heptane Constituents of The chief constituent of Jeffrey Pine oil heptane has been studied previously Investigation of non heptane constituents revealed *n* octylic, *n* nonylic and *n* decylic aldehydes In the present study, that portion of the oil of digger pine which boils above 110° was studied Aldehydes were removed by shaking with a 30% solution of sodium acid sulphite The solid addition product was separated, washed, the aldehydes regenerated with sodium carbonate and separated by steam distillation Ten fractions were obtained but melting points of derivatives were inconsistent so individual fractions were refracted Constants were determined and these are tabulated with those of previous workers *n* Octylic, *n* nonylic, *n* decylic and *n* myristic aldehydes were identified *n* Lauric aldehyde is indicated and there are indications of the presence of other aldehydes but it was not possible to obtain derivatives pure enough to characterize the compounds—ARTHUR H UHL *J Am Pharm Assoc*, 24 (1935), 390 (Z M C)

I-mao-tsao—Composition of Purple-Flowered A complete examination of i mao tsao (*Leonurus sibiricus* L.) is given but no positive evidence of alkaloids is found—TENG HAN TANG and CHI-WO HSÜ *Natl Shanglung Univ Chem Lab Repts*, 3 (1934), 93 through *Chem Abstr*, 29 (1935) 3115

Picrotoxin—Preparation of One kilogram of ground fish berries, *Anamirta cocculus* (L) Wight and Arn., is heated to boiling for 45 minutes with 2 liters of 95% ethanol filtered and the residue washed three times with 750 cc portions of hot alcohol The combined extract and washings are concentrated to 1 liter Two volumes of water at 75° are added with stirring to the hot concentrate, after which ice is added to make a volume of 5 liters When the ice is melted the liquid is separated from insoluble fatty material by filtration through folded filter paper The residue is washed with a liter of water and the combined filtrates are passed through a thin layer of norit in a small Buchner funnel The filtrate is concentrated under reduced pressure to 600 cc Crystals of picrotoxin are removed from the flasks from time to time After standing over night the crystals are removed from the mother liquor, washed with a little cold water, and dried A second crop of crystals is obtained upon further concentration The yield is about 1.4% of the drug and is quite pure except for a little coloring matter The analytically and optically pure product is obtained as follows 10 Gm of picrotoxin in 30 cc of hot acetone is filtered through a thin layer of norit upon a small Hirsch funnel and the adhering substance is washed from the apparatus with 15 cc of hot acetone The combined filtrate and washings are heated to boiling and three volumes of hot water are added Upon cooling well formed crystals having a melting point of $203-204^\circ$ separate—E P CLARK *J Am Chem Soc*, 57 (1935) 1111 (E B S)

Unclassified

Alkoxy-Cumarins—Relation between Odor and Constitution in the Case of Fifteen coumarin derivatives are discussed including the new compound 4 methyl umbelliferon ethyl ether which has a celery like odor and taste and appears to have some application as a seasoning agent—A ST PFAU *Rieckstoff-Ind*, 10 (1935), 57-58 (H M B)

Arsphenamine Aminohydroxybenzene-arsonic acid is electrolytically reduced in a

sulphuric acid medium, using lead electrodes with an iodide present as a catalyst —G A KIRKHOFF and O I KORZINA Russ Pat, 34,538 (Feb 28, 1934) (S W G)

Mercury Compounds—Study of Germicidal and Antiseptic Activity of Some The three compounds studied were 3,3'-dibromo-4,4'-dihydroxy-5-5'-diacetoxymercuri diphenyl dimethyl methane (I), 3,3 dinitro-4-4'-dihydroxy-5-5'-diacetoxy-mercuri diphenyl dimethyl-methane (II), and a mono acetoxy-mercuri derivative of 5',5'-dibromo resorcinol diphenol (III) A fourth product obtained from the last-named compound in which the position of the mercury was not determined was studied also Compounds I, II, IV showed useful germicidal activity Compounds I and IV were tested on tissues, I was non-irritating to shaved abraded skin, showed slight swelling in subcutaneous tissue on repeated injection autopsy showed no degenerative change Compound IV was slightly irritating to shaved abraded skin and caused slight swelling on subcutaneous injection and a scab at site of intradermal injection Details of experimental procedure are given Preparation of the compounds was along familiar lines, mercuration of suitable intermediates being effected in boiling alcohol solution —E MONESS, S E HARRIS and W G CHRISTIANSEN *J Am Pharm Assoc*, 24 (1935), 386 (Z M C)

Ortho-Aminophenol—Acyl Derivatives of When diacyl derivatives of *o* aminophenol were prepared by the usual methods it was found that the order of introduction of the two different acyl groups gave identical rather than isomeric products indicating that a rearrangement must have occurred in one case Positions of the acyl groups were determined by removing the group attached to the oxygen by saponification and determining from physical constants of the mono-acylated product the group attached to the nitrogen Formation of isomeric diacyls and production of the same saponification products indicates rearrangement occurred during saponification Experimental evidence indicates that certain acyl groups have more influence than others The present investigation was a further study of the factors of rearrangement The acylating agent was *o* *n* heptanoyl chloride, this group being heavy and less acidic than any group against which it was introduced This group was introduced against the *n* butyryl, *n*-valeryl, *n*-caproyl, phenyl-acetyl and hydrocinnamyl groups The authors reached the following conclusion "Apparently relative weight and acidity are not the controlling factors in this type of rearrangement When complete rearrangement did occur, the nitrogen atom was shown after saponification to be attached to the heavier and less acidic group in three cases and to the lighter and less acidic group in one case One case showed only partial rearrangement In this case, saponification products showed part of the nitrogen to be attached to the heavier and more acid group while the remainder of the nitrogen was attached to the lighter and less acidic group" Experimental details are reported Properties of the two monoacyls prepared are given The ten diacyl derivatives prepared are named, formulas given, analyses given Saponification products are also given Some of the compounds are being studied for antiseptic and physiological effects and the results of this study will be published later —C B POLLARD and W T FORSEE, JR *J Am Pharm Assoc*, 24 (1935), 363 (Z M C)

BIOCHEMISTRY

Chemistry—Some Recent Contributions of, to Medicine Among the contributions discussed are vitamins hormones choline and related compounds, and anesthetics —R T MAJOR *J Soc Chem Ind* 54 (1935), 447 (E G V)

2-4 Dinitrophenol—Effect of Repeated Washing on Stimulation of Yeast Respiration by Washing has no influence It is concluded that dinitrophenol acts directly on systems within the cell and that extracellular catalysts are not essential for such action —J FIELD, 2ND and A W MARTIN *Proc Soc Exptl Biol Med*, 32 (1935), 1285 (A E M)

Estrin—Extraction of, from Female Urine after Acidification with Various Acids Urine acidified with tartaric acid produced the greatest yield of estrin —W KENNETH CUYLER *Proc Soc Exptl Biol Med* 32 (1935) 1352 (A E M)

Food Chemistry—Twenty-Five Years of A review covering fundamental advances made in the study of the ingredients of foods —L H LAMPITT *J Soc Chem Ind*, 54 (1935), 426 (E G V)

Gonad-Stimulating Product Blood is taken from pregnant mares which are between the 37th and 130th day of gestation, and the serum is obtained from the blood —H H COLE and G H HART U S Pat, 1, 994,853 (Mar 19, 1935) (S W G)

Insulin—New Method for Precipitation of Insulin is removed quantitatively from aqueous solutions as a bluish precipitate by the addition of 0.2% potassium ferrocyanide solution. For very pure insulin about 0.1 mg potassium ferrocyanide is required to precipitate 100 units, commercial products require 0.6–2.0 mg since other substances present are also precipitated. The filtrate in all cases contains inactive protein derivatives which precipitate with picric acid. Good commercial insulins containing 20–22 units per mg dry substance yield a dried ferrocyanide precipitate, weighing 4–6 mg per 100 units. Less refined products yield precipitates weighing 7–10 mg per 100 units, and hence the quality can be judged by the weight of the precipitate. The insulin ferrocyanide precipitate (Ferrinsulin) can be dissolved in 2% sodium acid phosphate solution and injected. In rabbits its action is less marked but more prolonged than that of ordinary insulin.—I. I. NITZESCU and S. SECAREANU *Bull soc chim biol*, 17 (1935), 118, through *Chem Abstracts* 29 (1935) 3463

Phenol—Partition of, between Olive Oil and Serum in Ascitic Fluid. Quantitative determinations are reported of the content of phenol in serum or ascitic fluid after reaching equilibrium of partition with phenol solutions in olive oil. The phenol is determined by Wilkie's iodine method (*J Soc Chem Ind*, 30 (1911), 398). The partition coefficient of phenol between the olive oil and the serum or ascitic fluid is found to be of the same order as the partition of phenol between olive oil and water. Hence it is concluded that the proteins of the serum do not bind significant amount of phenol. The relationship is shown in a graph.—A. HEEDE and S. STENSIG *Dansk Tids Farm* 9 (1935) 86 (C S L)

Pregnancy Diagnosis. A review of the different methods is given. The procedure of Joel and Andreani-Constantin using male guinea pigs of one month of age was investigated. The injection of 2 cc of urine was made into the heart and the hypertrophy of the sexual organs was observed after 48 hours. The results were reliable.—LUIS S. GISMONDI and BENIGNO S. ACEVEDO *Semana med* (Buenos Aires) 42 (1935), 1194 (A E M)

Vitamin Synthesis—A comprehensive review of the properties leading to and the methods of synthesis of the vitamins. The syntheses of vitamins A, B₂ and C are described in detail with the aid of structural formulae. A graphic formula of ergosterin is given.—OSKAR BAUER *Pharm Zentralh*, 76 (1935) 129 (E V S)

Vitamin B₁—Studies of Crystalline VIII Sulphite Cleavage. II. Chemistry of the Acidic Product. The chemistry of the acidic product, C₆H₅N₃SO₃ (I), obtained by the sulphite cleavage of vitamin B₁ is given. It has the properties of a sulphonic acid. Heating with moist sodium hydroxide at 185° eliminated the sulphur as alkali sulphite and water at 200° yielded sulphuric acid. Refluxing with strong hydrochloric acid removed 1 mole of ammonia yielding C₆H₅N₃SO₄ (II). Further study showed a similarity between (I) and 6-aminopyrimidine, and between (II) and 6-oxypyrimidine.—ROBERT J. WILLIAMS, EDWIN R. BUCHMAN and A. E. RUEHLE *J Am Chem Soc*, 57 (1935), 1093 (E B S)

Vitamins. A review of the progress made in the isolation, synthesis and determination of the constitution of these bodies.—P. KARRER *Pharm Monatsh* 16 (1935) 48–50 (H M B)

Vitamins—History of the Discovery of. A brief historical review of the discovery and the physiological and therapeutic actions of the known vitamins.—G. ROLAND *J pharm Belg*, 17 (1935) 111–115 (S W G)

Urine—Simple Method for Determination of Glucose in. The author describes the determination of glucose in urine with the aid of a trade preparation "Glucocord" whose precise composition is not given but which consists of a pulverized alkali hydroxide mixed with a reducible metal compound and a physical activator. The unfiltered urine is dropped onto a small quantity of the powder placed on a white glass or porcelain plate, and if sugar is present the powder blackens to a degree dependent on the sugar content.—E. KARLING *Farm Revy*, 34 (1935), 249 (C S L)

ANALYTICAL

Ammonium Molybdate—Use of, as a Microchemical Reagent. The author suggests ammonium molybdate as a microchemical reagent for the detection of the salts of various metals. Crystalline ammonium molybdate is added to the drop in which the metallic salt is dissolved. **Aluminum**.—While the reagent is not specific for aluminum it has several advantages over the two customary microchemical reactions. The crystals are square or rectangular. **Manganese**.—Reactions with the sulphate and chloride were investigated. The reaction proceeds slowly. Upon

evaporation orange-brown prismatic plates are formed near the edge of the drop, ending in a pyramid (vertical angle 104°) or obliquely (angle 54°). The reaction gives good results even in the presence of aluminum and zinc. *Zinc, Nickel, Cobalt, Iron, Copper* and *Mercury* give similar forms to those obtained with Aluminum. *Zinc*—Reaction not sensitive, in the presence of manganese negative. *Nickel*—An amorphous precipitate slowly becoming crystalline. *Cobalt*—Crystallizes slowly after evaporating and moistening with water. *Copper*—Squares with rounded corners. *Mercury*—Many square plates and right angled prisms. The reaction is very sensitive. *Thallium*—Long needles, reaction sensitive. *Silver Nitrate*—Diamond and octahedral shapes. *Uranyl, Lead, Cadmium* and *Bismuth* salts gave no useful reactions. *Ferrous Sulphate*—Wine red coloration but no precipitate or crystals. *Lithium, Magnesium* and *Calcium* salts (except in large concentration) give no reaction. *Strontium* and *Barium* acetate show little tendency to form crystals. *Cerium Nitrate*—Droplets which upon scratching give orange parallelograms, diamond shapes and long needles. The author concludes that next to its use in demonstrating phosphoric acid, ammonium molybdate is a useful reagent in identifying aluminum, manganese and cerium salts.—C. VAN ZIJP *Pharm Weekblad*, 72 (1935), 414 (E. H. W.)

Arsenobenzene Derivatives—Assay of Several. Twenty four preparations of arsenobenzene derivatives were tested for toxicity and therapeutic value. A preparation was non toxic if a dilute solution did not exceed 40% mortality in mice and a stronger solution did not exceed 50% mortality in mice and 40% mortality in rats. Mice infected with trypanosomes were used to test therapeutic value. A standard was used and the preparation had to be as active as the standard. None of the preparations compared favorably with the standard requirements, all being either deficient in therapeutic value or too toxic. Tables of results are given.—M. ROTHERMUND *Deut Med Wochschr* 61 (1935), 92-95 (H. R.)

Caffeine—Micro-Determination of, by Colorimetry. The modified Weidel method (*Bull soc pharm Bordeaux*, 72 (1934), 345) is used to obtain an alcoholic solution of the caffeine. The sample should contain 0.1-2.0 mg of the ureide. Evaporate the alcoholic solution to dryness by gentle heating in a porcelain dish, with a handle about 5 cm in diameter. Add 6 drops of saturated bromine water and 9 drops of *N* hydrochloric acid. Mix, then evaporate to dryness by moving the container around below the top of a Bunsen flame, then continue heating in the same manner until the entire surface of the residue becomes orange red without traces of yellow and without evident calcination. Add 1 drop of 5% mercuric acetate in water acidified with 2% acetic acid, mix with a glass rod to dissolve the residue and introduce the colored liquid into a tube with a diameter of 12-15 mm. Compare the color with a series of standards prepared as above containing from 0.1 to 1.2 mg of caffeine. Two drops of a 5% solution of zinc acetate plus 1 drop of glacial acetic acid may be substituted for the mercuric acetate. The orange red residue obtained as above may be dissolved in water to give a rose colored liquid which may be compared colorimetrically, but this is not as good as the other procedures.—GEORGES DENIGES *Bull soc pharm Bordeaux*, 73 (1935), 5-7 (S. W. G.)

Cantharidin—New Microchemical Reaction of. The following procedure is given. Place several particles of the sample on a slide and cover with a drop of concentrated ammonia water. Heat over a small alcohol lamp flame to evaporate the ammonia water, removing the flame while a small moist surface remains to be evaporated by the heat retained by the slide. Examine the dried product under a magnification of 400-500 \times . This product may be sublimed with gentle heat, collecting the sublimate on a superimposed slide and after moistening with a droplet of C_6H_6 and evaporation of the solvent microscopic crystals of cantharidin are formed.—GEORGES DENIGES *Bull soc pharm Bordeaux*, 73 (1935), 7-9 (S. W. G.)

Cholesterol—Fixed Color Standard for, Determination of. A fixed color standard for use with Schoenheimer's and Sperry's micro method for serum cholesterol is described. The use of a mixture of acetic anhydride and sulphuric acid is suggested.—ARTHUR SHAPIRO, HENRY LERNER and EDNA POSEN *Proc Soc Exptl Biol Med*, 32 (1935), 1300 (A. E. M.)

Cinchona—Identification of Preparations of, by the Erythroquinine and Thalleoquinine Reactions. The drug or preparation is extracted several times with chloroform and acidulated water and finally with chloroform. To 2 cc of the chloroform extract add 3 cc of acetic acid (1%) and note the appearance of a blue fluorescence. Then add bromine water (1:10) drop by drop until a persistent yellow color is obtained. Add a 1:10 solution of potassium ferrocyanide using 1 drop of the solution for every 5 drops of bromine water added, then make alkaline with

ammonia (1 10) A rose to red color is obtained depending on the amount of quinine present The thalleoquinine reaction a modification of the above erythroquinine reaction, is not as specific nor as sensitive —M R MONNET *J pharm chim*, 21 (1935), 450 (M M Z)

Citral—Reaction for the Identification and Determination of Alcoholic solutions of methylene blue react with sodium hydroxide to change from blue to rose and this reaction is hastened by citral in addition to other substances Five cc of a mixture containing 1 drop of a 1% solution of methylene blue in methyl alcohol and 20 cc of *N*/10 sodium hydroxide is mixed with 1 cc of a dilute solution of citral in methyl alcohol When mixed at 15° an immediate change from blue to red is apparent if 1 mg of citral is present If a smaller amount of citral is present the color change occurs slowly The reaction may be used quantitatively by comparing the color developed with standards Many other substances give similar reactions, but a longer time is required if 1 mg or less is present —J BOUGAULT and E CATTELAINE *J pharm chim*, 21 (1935), 437 (M M Z)

Colloidal Silver—Determination of, in Organic Medicinals Application to Ointments The different methods used for the destruction of organic compounds containing silver are discussed, and the determination of silver is criticized The use of nitroperchloric acid or nitro sulphoperchloric acid is recommended for decomposing silver organic compounds This can be carried out as follows especially in the case of ointments A weighed sample of about 0.1 Gm to 0.3 Gm is introduced into a 100 cc Erlenmeyer flask followed by 3 cc of sulphuric acid ($d = 1.84$) and 5 cc nitric acid ($d = 1.38$) The mixture is warmed until brown fumes are no longer apparent, and a mixture of 3 parts of perchloric acid ($d = 1.61$) and 1 part of nitric acid ($d = 1.38$) is then added drop by drop until the liquid is decolorized The mixture is then boiled for 1 or 2 minutes to expel the excess hydrochloric acid generated It is then cooled, 20 cc of distilled water and 2 cc saturated iron alum solution are added and the silver determined by titration with 0.1*N* potassium sulphocyanate This method gives maximum accuracy in minimum time according to the author —GEORGES ANTOINE *J pharm chim* 21 (1935) 457 (M M Z)

Copper—Quantitative Microdetermination of A comparative study was made of three methods of evaluation (a) precipitation by means of 5,7 dibrom 8 oxyquinoline (5,7 dibrom oxime") according to R Berg and H Kustenmacher, (b) precipitation as copper benzoin oxime according to F Feigl and to R Strebinger (c) precipitation as copper salicylaldoxime according to F Ephraim and to W Reif Suitable techniques were devised in all three cases for the microdetermination of copper Of the three methods, (a) was found to be the most precise, since the conversion factor is lowest in this instance —F HECHT and R REISSNER *Mikrochem* 17 (1935), 127 (L L M)

Copper—Determination of Small Quantities of The following method was proposed A dithizone (diphenylthiocarbazon) solution (0.1 Gm in 50 cc of carbon tetrachloride) is shaken with two 50 cc portions of dilute ammonium hydroxide (1 + 99) The combined ammoniacal extracts are slightly acidified with hydrochloric acid the precipitated dithiazone filtered off, washed with water and dried A 100 cc portion of a 0.01% solution of the dithizone in carbon tetrachloride is shaken with an equal volume of water containing 0.5 cc of ammonium hydroxide The carbon tetrachloride layer is discarded This is repeated until only a trace of pink color is seen in the carbon tetrachloride layer The dithizone is precipitated with hydrochloric acid and extracted with carbon tetrachloride, and the solution is made up to the desired strength Two hundred cc of a solution containing 12 Gm of sodium pyrophosphate and 0.5 Gm of sodium carbonate is shaken with 50 cc of a 0.01% solution of dithizone in carbon tetrachloride The carbon tetrachloride layer is discarded This is repeated until only a trace of pink color remains The dithizone remaining is extracted from the solution with amyl alcohol the amyl alcohol removed with carbon tetrachloride The solution should be re tested before using The sample is ashed in a silica dish at about 500° C The ash is dissolved in water and made up to volume A 10-cc portion of the solution containing not over 0.005 mg of copper is made neutral to methyl orange with ammonium hydroxide acidified with a 2 cc excess of concentrated nitric acid and extracted with 3 cc of 0.003% dithizone in carbon tetrachloride The carbon tetrachloride extract is washed with water, acidified with a few drops of hydrochloric acid The washed carbon tetrachloride solution is then shaken with a solution containing 5 cc of water and 5 cc of the pyrophosphate-carbonate solution and the resulting solution compared in a Nessler tube with standards

containing 0.0005 and 0.001–0.005 mg of copper in increments of 0.001 mg. A blank is also used.—R. M. MEHURIN *J. Assoc. Official Agr. Chem.*, 18 (1935), 192 (G. S. W.)

Digitalis—Baljet Color Reaction of Compounds of The Baljet colorimetric method for the determination of glucosides is also suitable for the determination of genins. It consists in treating the compound with sodium picrate and comparing the color maximum developed with a standard solution of potassium dichromate. Determinations were compared for digitoxin, digitoxigenin, gitoxin, gitoxigenin, g- and k-strophanthin, strophanthidin and digiland A. The reaction was more intense for the aglucones, genins, than for the glucosides and more intense for the lower molecular weight compounds. The development of the color seems to be associated with the unsaturated hydroxylactone group. Scillaren A did not give the Baljet reaction nor other reactions characteristic for the unsaturated lactone group of the glucoside. The test is not specific for the unsaturated lactone group of the glucoside. The test is not specific for the genins since dextrose also gives the color reaction, however, comparison of the sensitivity and the time required for the development of the color indicates that small amounts of dextrose will not interfere with the determination of the glucosides.—L. LENDLE and W. SCHMELZER *Arch. exp. Path. Pharmacol.*, 177 (1935), 622, through *Squibb Abstr. Bull.*, 8 (1935), A 694.

Drinking Waters—Determination of Lead in Methods sufficiently accurate to determine 0.0001–0.0300 mg of lead per liter are necessary. Water that has been freshly drawn from the tap should be used since it has been found that lead in colloidal forms as lead hydroxide, basic carbonate and hydrocarbonate are present, and these after a time become attached to the walls of the vessel and cannot be removed by shaking, thereby giving low results. The sample should be treated as follows: "Transfer all of the sample to a flask, retaining about 10 cc. to which add dilute acetic acid (5 cc. per liter), shake vigorously to dissolve the lead on the walls of the vessel. Return the portion of the sample that was removed, allow to stand until the bubbles of carbon dioxide have subsided." Turbid waters or those in which iron has separated should not be filtered since such suspensions retain the lead to such an extent that all of it may be removed and these should be treated as under "Turbid Waters." Methods are given for clear and colorless waters, turbid and slightly colored waters, and strongly colored (humous) waters. Special treatments to eliminate errors due to the presence of copper, nitrite, iron and aluminum are given.—K. HOLL *Apoth. Ztg.*, 50 (1935), 126–128 (H. M. B.)

Fluorine—Determination of, in Foods In the use of lime as a fixative for fluorine during ashing of samples it was found necessary to employ a large excess of the lime. For determination of very small amounts of fluorine, the lime must be treated to remove fluorine present as an impurity. Suggested methods for purification are distillation with perchloric acid followed by recovery of the calcium as the carbonate, or precipitation of calcium as the oxalate. In either case the precipitates are converted to the oxides by incineration.—D. DAHLE *J. Assoc. Official Agr. Chem.*, 18 (1935), 194 (G. S. W.)

Iodine Number—Rapid Method for the Determination of The method of B. M. Margosches was adapted to a micro technique. One cc. of solvent, 2 cc. of *N*/5 alcoholic iodine solution and 20 cc. of water were used in the micro method. The iodine was titrated with *N*/20 sodium thiosulphate.—W. RUZICKA *Mikrochem.*, 17 (1935), 215 (L. L. M.)

Iron—Determination of Metallic, in Presence of Iron Oxides Reduced Iron The copper sulphate method for the determination of metallic iron in reduced iron has been shown to yield inaccurate and variable results. The following modification of the Wilner-Merck process is recommended. To about 0.5 Gm. of sample, accurately weighed, in a clean, dry 100-cc. graduated flask, add 2.5 Gm. of mercuric chloride (sulphide free) and about 50 cc. of recently boiled and cooled distilled water. Boil gently for 20 minutes (avoiding excessive frothing) with frequent shaking, make the volume up to 100 cc. with recently boiled and cooled distilled water, stopper the flask and cool. When cold, adjust the volume to 100 cc., shake well, allow the precipitate to settle, filter rapidly into a clean, dry conical flask, pipette 50 cc. of the filtrate into 100 cc. of dilute sulphuric acid in which 2 Gm. of manganese sulphate has been dissolved and titrate with 0.1*N* potassium permanganate solution. The experimental work reported is tabulated.—F. HARTLEY, W. H. LINNELL, F. E. READ and H. G. ROLFE *Quart. J. Pharm. Pharmacol.*, 8 (1935), 100–112.

(S. W. G.)

Lime and Bleaching Powder—Presence of Manganese in Commercial All the samples of commercial lime and bleaching powder examined showed the presence of small amounts of manganese. The manganese was determined colorimetrically by an application of the periodate method as follows. In the case of samples of bleaching powder, quantities of 1 Gm. were treated with 7 cc. of water and 30 cc. of concentrated nitric acid, evaporated to small hulk, treated with a further 7 cc. of nitric acid, and again partially evaporated. The hot solution, which was now free from chloride, was treated with 5 cc. of nitric acid and 0.4 Gm. of potassium periodate, boiled for one minute, kept hot for 10 minutes, cooled, diluted to 100 cc. and compared colorimetrically with standards prepared from varying quantities of manganese sulphate by oxidation with periodate. In the case of samples of lime the double evaporation with nitric acid is unnecessary. Seventy-seven to 137 parts of manganese per million were found. The authors prove that the pink coloration of preparations from bleaching powder especially those containing sodium bicarbonate is due to the presence of manganese and not iron as has been claimed.—JOHN E. DRIVER and HUBERT A. TURNER *Quart. J. Pharm. Pharmacol.*, 8 (1935), 113-115 (S. W. G.)

Luminescence Analysis—Advances in Progress in the use of ultraviolet light in qualitative and quantitative analysis is reviewed and a new portable analytical lamp is described.—A. KARSTIN *Pharm. Monatsh.*, 16 (1935), 45-47 (H. M. B.)

Magnesium and Aluminum—Microchemical Detection of, with Alkannin and Naphthazarin
A Detection of Magnesium with Alkannin and Naphthazarin in Sodium Hydroxide Solution—Add to 5 cc. of the test solution 5 drops of a 0.05% alcoholic solution of alkannin or a 0.03% solution of naphthazarin and then dropwise a slight excess of 2.5N sodium hydroxide. Depending upon the magnesium content a blue precipitate appears at once or upon warming.
B Detection of Magnesium with Naphthazarin in Ethylenediamine Solution—In a micro test tube add several drops each of the solution to be tested and of the reagent. The latter consists of a mixture of 5 cc. of 0.03% naphthazarin solution and 1 cc. of 10% ethylenediamine solution. In the presence of magnesium a blue coloration is formed. The limit of sensitivity is 0.35% magnesium, corresponding to a concentration of 1/66,000.
C Detection of Aluminum with Alkannin and Naphthazarin—Add to the test solution 2 cc. of alkannin or naphthazarin reagent, then with constant agitation enough ammonia water to change the dark red color to blue, and finally an additional 3 cc. of ammonia water. A dark violet precipitate results. With alkannin, 0.1 mg. of aluminum is detected in the cold; 0.05 mg. upon warming, with naphthazarin, 0.05 mg. of aluminum in the cold in 15 minutes. In the presence of a five fold quantity of zinc, there may be detected only 0.5 mg. of aluminum in the cold; 0.1 mg. by heating with alkannin and 0.5 mg. in the cold with naphthazarin.—J. V. DUBSKÝ and E. WAGNER *Mikrochem.*, 17 (1935), 186 (L. L. M.)

Mardulean—Determination of Iron in The iron is present as colloidal ferric hydroxide mixed with sugar and alkali. The preparation is required to contain 0.21% iron but no assay is prescribed. The following assay is proposed. 20 Gm. of Mardulean is warmed with 10 Gm. of diluted sulphuric acid in an Erlenmeyer flask until the red-brown color is changed to a bright yellow. Traces of ferrous sulphate which may be present are converted into ferric sulphate by treatment with a few drops of 0.5% potassium permanganate solution. After cooling, the solution is mixed with 2 Gm. of potassium iodide and allowed to stand for one hour. The liberated iodine is titrated with N/10 sodium thiosulphate. If 0.21% iron is present 20 Gm. of Mardulean will require 7.53 cc. of N/10 sodium thiosulphate.—G. MEYER *Pharm. Ztg.*, 80 (1935), 324 (G. E. C.)

Medicinal Products—Study of the Alteration of, by pH Determinations A pH study was made of the following: distilled water, emetine hydrochloride solution (0.1%), morphine hydrochloride solution (2%), pilocarpine hydrochloride solution (0.1%), strychnine sulphate solution (0.1%), stovaine hydrochloride solution (5%), novocaine hydrochloride solution (2%), citrate of magnesia, Fowler's solution, sodium bicarbonate solution (1%), infusions and decoctions, syrups, sodium phosphate solutions, silver nitrate solutions and aspirin, thiocol, neosalvarsan and phenol solutions. The preparations were allowed to stand for 1 year and pH determinations were made from time to time. The changes noted are tabulated. The authors suggest that a pH determination should be a part of every assay of preparations.—A. IONESCU MATIU and M. SANDOVICI *J. Pharm. chim.*, 21 (1935), 337 (M. M. Z.)

Morphine—Colorimetric Microdeterminations of, in Opium and Its Preparations Tincture of Laudanum and Syrup of Morphine Hydrochloride. The author gives the official method

for isolating morphine from its preparations by use of slaked lime, dilute hydrochloric acid and ammonia. The microdetermination suggested follows: Into 10 colorimetric tubes are introduced, respectively, from 1 to 10 cc of morphine hydrochloride solution (1:10,000) and 1 cc of Wavelet's reagent (140 Gm sodium carbonate and 20 Gm disodium phosphate dissolved in 500 cc distilled water plus 70 Gm of recently dried inosilicic acid and 200 Gm of tartaric acid, and the mixture diluted to 1 liter). To each tube is then added 1 drop of nitric acid. This is permitted to stand for 10 minutes, agitated and diluted to an even level in each tube. Finally 20 drops of ammonia water are added to each tube and mixed, when a blue color is obtained the intensity of the color being proportional to the amount of alkaloid present. This is used as a standard, and 6 tubes are used for the sample in the same manner. The method cannot be used if adrenaline is present, as it gives an identical color.—JUAN A. SANCHEZ *J. pharm. chim.*, 21 (1935), 366 (M. M. Z.)

Morphine—Estimation of, in Opium. The author describes a method for the determination of morphine in opium and opium preparations in which the alkaloid is shaken out. The material is prepared with sodium hydroxide and a solution of sodium plumbate added. After filtering, the excess lead is precipitated from an aliquot portion with sulphuric acid and again filtered. The sulphuric acid in the filtrate is neutralized, a definite acidity then being obtained by the addition of a small quantity of hydrochloric acid. The solution is then concentrated, made alkaline with sodium hydroxide and the other associated alkaloids shaken out with chloroform. The chloroform solutions are freed of any morphine with dilute sodium hydroxide. After combining the sodium hydroxide solutions they are made weakly acid by the addition of hydrochloric acid, chloroform isopropyl alcohol is added and the hydrochloric acid is neutralized with a quantity of sodium bicarbonate sufficient to cause the free alkaloid to go over into the chloroform mixture. After evaporation of the solvent the alkaloid is titrated.—F. SZECHELY *Ber. Ungar. Ph. Ges.* (1935) 316, through *Pharm. Weekblad*, 72 (1935) 517 (E. H. W.)

Morphine—Reaction for, in Papaverine Hydrochloride. The iodine liberated from iodic acid in testing for morphine in papaverine hydrochloride cannot be shaken out with chloroform. This is due to the fact that papaverine hydrochloride is easily soluble in chloroform. It is, however, only slightly soluble in carbon tetrachloride and carbon disulphide. A small quantity of iodine was dissolved in chloroform, carbon tetrachloride and carbon disulphide and 50 mg of papaverine hydrochloride added to each. The chloroform solution became lighter and finally changed to yellow or reddish yellow while no change occurred in the other solutions. Fifty mg of papaverine hydrochloride were added to three test-tubes containing a water solution of iodine (+ potassium iodide) (+ a few drops of dilute sulphuric acid). The brownish red cloudy precipitate due to the iodine-papaverine compound resulted. The aqueous solutions were then shaken out, one with chloroform, one with carbon tetrachloride and one with carbon disulphide. The precipitate dissolved in the chloroform imparting a yellowish color. The carbon tetrachloride and the carbon disulphide became reddish violet. Subsequent addition of potassium iodate to each tube resulted in no change in the chloroform and a deep violet in the carbon tetrachloride and the carbon disulphide. The author suggests that carbon tetrachloride or better carbon disulphide be substituted for chloroform in this test.—J. ROZEBOOM *Pharm. Weekblad* 72 (1935), 498 (E. H. W.)

Ointment of Mercuric Nitrate, Strong—Assay of. The authors tried the procedures suggested by other workers and found that none of them gave results higher than those obtained by the method of the Brit. Phar. 1932. They recommend the following modification of the official process, using a volumetric determination of the mercury instead of the gravimetric determination as the sulphide. Take about 5 Gm, accurately weighed, in a long-necked flask of about 250 cc capacity. Add 35 cc of sulphuric acid and heat cautiously until the mixture darkens. Add gradually 5 cc of fuming nitric acid, rotating the flask to assist the escape of evolved gases. Heat and maintain just below the boiling point. Repeat several times the addition of fuming nitric acid and the heating, until an almost colorless solution remains. Cool, add a slight excess of solution of potassium permanganate and heat to boiling. Add sufficient solution of hydrogen peroxide to make the solution colorless, cool and dilute to 250 cc. Titrate 100 cc with 0.1N ammonium thiocyanate using solution of ferric ammonium sulphate as indicator. The treatment with permanganate is carried out to remove the color from the solution and to thus aid in obtaining a sharp end point in the titration.—C. H. HAMPSHIRE and G. R. PAGE *Quart. J. Pharm. Pharmacol.* 8 (1935), 75-80 (S. W. G.)

Organic Compounds—Detection of, by Means of Spot Reactions IX. (1) **Detection of Acetic Acid by Formation of Indigo Dyes** The method for the detection of acetic acid is as follows. A drop of the test solution is evaporated to dryness with calcium carbonate and the dried residue is transferred to the small fusion tube illustrated in the diagram. The conversion of the acid to calcium acetate may be effected also by direct evaporation in this tube under reduced pressure. In the former case the solid samples to be tested may be placed directly in the tube with a quantity of calcium oxide and calcium carbonate. The open end of the tube is covered with a small filter disk moistened with a freshly prepared solution of *o* nitrobenzaldehyde (saturated solution in 2*N* sodium hydroxide). The tube is supported in an asbestos plate as shown and gradually heated. According to the quantity of acetone formed the filter paper, after an intermediate browning, becomes colored blue or blue green. With small quantities of acetate, it is advisable to moisten the filter disk after distillation with a drop of diluted hydrochloric acid to remove the yellow color of the indicator and thus permit the blue color to come into prominence. The method is applicable to the detection of the acetyl residue in organic compounds. The limit of sensitivity is 60γ acetic acid. *Test for Methyl Ketones*—A drop of the test solution, as nearly alcohol free as possible, is warmed gently in a micro eprouvette on a water-bath with a drop of alkaline *o* nitrobenzaldehyde solution (saturated solution in 2*N* sodium hydroxide) and, after cooling is shaken with chloroform. Methyl

ketones are indicated by a bluing of the chloroform layer. With alcoholic solutions a red instead of blue coloration is sometimes observed. The reaction detects 100γ acetone, 150γ methyl ethyl ketone, 150γ methyl heptenone, 50γ acetophenone, 200γ acetyl acetone, 40γ diacetyl, 300γ acetoacetic ester, 100γ acetaldehyde.—F. FEIGL, R. ZAPPERT and S. VASQUEZ, *Mikrochem.*, 17 (1935), 165 (L. L. M.)

Pepsin—Assay Processes and Stability of Commercial

The samples of commercial pepsins examined were found to conform with their stated values. The Brit. Phar., U. S. Phar. D. A. B. and edistin methods of assay are compared. Suggested improvements in the Brit. Phar. process are: (1) Substitution of a wire sieve for the hair sieve. (2) Allow only 15 minutes for dissolving the pepsin. (3) Digest for 3 hours instead of 6 hours, using a larger quantity of pepsin and shaking every 10 minutes. (4) The tolerated amount of albumen remaining undigested should be accurately described. (5) Digest at 50–52° C. (6) Define the hydrochloric acid in terms of normality. The author suggests the adoption of the U. S. Phar. procedure with the following modifications: (1) To disintegrate the albumen

‘Rub 10 Gm. of the prepared egg white gently in a small glass mortar with 10 cc. of the diluted hydrochloric acid and, when thoroughly distributed, transfer to the digestion bottle with a glass rod, wash the pestle and mortar and the glass rod with further quantities of 10, 5, 5, 5 cc. of diluted hydrochloric acid, in this way transferring every particle of albumen to the digestion bottle.’ (2) 0.2 Gm. of the pepsin to be weighed out and made up to 300 cc. with acid to form the test solution. The value of carrying out at least 6 tests with each sample or using a standard pepsin is stressed.—KENNETH BULLOCK, *Quart. J. Pharm. Pharmacol.* 8 (1935), 13–30 (S. W. G.)

Pharmacopœial Tests—Notes on Some II. Chiniofon, Codeine, Simple Solution of Iodine, Sodium Phosphate. *Assay of Chiniofon*—The following procedure was adopted for the determination of iodine. Mix about 0.2 Gm., accurately weighed, with about 1 Gm. of anhydrous sodium carbonate in a nickel crucible 20 mm. in diameter, moisten with water, and dry at 100°. Fill the crucible completely with anhydrous sodium carbonate well pressed down, invert the crucible and contents in a nickel crucible, 25 mm. in diameter containing a layer of anhydrous sodium carbonate and add more anhydrous sodium carbonate to seal the junction of the two crucibles. Heat for 15 minutes over a Bunsen flame in such a manner that the outer crucible is a uniform dull red, allow to cool, and dissolve the residue in 100 cc. of hot water, filter, and wash the filter with water until the washings are neutral to litmus. Allow the solution to cool and add sufficient

water to produce about 500 cc. Neutralize the solution with a mixture of equal volumes of sulphuric acid and water using methyl orange as indicator. Add 1 cc. of sulphuric acid (1:1), 0.2 cc. of bromine and about 0.05 Gm. of iodoform and boil briskly for 10 minutes. Allow to cool, add 0.2 cc. of a 25% w/v solution of phenol in glacial acetic acid and allow to stand for at least 2 minutes. Add 2 Gm. of potassium iodide and titrate with *N*/10 sodium thiosulphate using mucilage of starch as indicator. Each cc. of *N*/10 sodium thiosulphate = 0.002115 Gm. of iodine.

Determination of Sodium Bicarbonate—Place about 0.5 Gm., accurately weighed, in a dry test-tube 150 mm. in length and 20 mm. in diameter and insert a loose plug of glass wool about half way down the tube. Place the test tube in a 750 cc. filtering flask containing 50 cc. of *N*/10 barium hydroxide. Close the neck of the flask with a stopper, through which passes the tube of a 50-cc. separating funnel, in such a manner that the tube of the separator enters the test tube. Exhaust the flask rapidly until a pressure of 20 mm. of mercury is obtained, and close the exit tube. From the separating funnel add gradually 10 cc. of freshly boiled and cooled water, and, when effervescence has ceased, about 1 cc. of dilute hydrochloric acid. Allow to stand for at least 12 hours, and titrate the excess of *N*/10 barium hydroxide with *N*/10 oxalic acid, using phenolphthalein as indicator. Each cc. of *N*/10 barium hydroxide = 0.0042 Gm. of sodium bicarbonate. Results of analyses of commercial samples are tabulated.

Solubility of Codeine in Ether—The solubility of codeine monohydrate in ether as stated in the literature is noted. The official alkaloid, containing one molecule of water of crystallization, was found to dissolve 1 Gm. in approximately 75 Gm. of ether. The saturated solution had a specific gravity of 0.728.

Changes in Simple Solution of Iodine on Storage—The following conclusions are stated. When simple solution of iodine is stored the content of free iodine becomes constant in 8 months. The acidity of the solution still increases slightly after the free iodine content has become constant. The rate of chemical change and the composition of the final equilibrium mixture are not appreciably affected by light. The results are tabulated.

Detection of Traces of Sodium Fluoride in Sodium Phosphate—The following procedure was adopted. Dissolve 2 Gm. of the sodium phosphate in 20 cc. of water, add 5 cc. of acetic acid and 3 cc. of solution of calcium chloride and set aside for 1 hour, no turbidity is produced. The test will detect 0.2% of sodium fluoride in sodium phosphate. Other tests were tried, but none were more sensitive.—G. R. PAGE *Quart. J. Pharm. Pharmacol.*, 8 (1935), 81-89 (S. W. G.)

Potassium Ferrocyanide—Toxicologic Study of, as a Clarifier for White Wines—Toxicologic procedures were applied to the detection of cyanide derivatives in wines that had been clarified by means of potassium ferrocyanide. The results obtained indicate that the question is open to further investigation.—CHELLE, DUBAQUIS and TURBET *Bull. soc. pharm. Bordeaux*, 73 (1935), 9-42 (S. W. G.)

Purine Preparations—Cobalt Nitrate as a Reagent for Pharmaceutical—A 3% alkaline solution of cobalt nitrate is recommended as a reagent for identifying theobromine, theophylline, caffeine and such combinations as diuretin and caffeine tartrate. Directions are given for performing the test.—R. KLIMEK *Wiadomosci Farm.*, 61 (1934), 619, through *Chem. Abstr.*, 29 (1935), 3115

Pyrimidon—Coloring of, by Certain Oxidants—Pyrimidon is very sensitive toward the influence of oxidizing agents, often resulting in highly colored compounds. The urine of persons who have taken pyrimidon is frequently colored red or light purple due to the oxidation of the pyrimidon. The obtaining of beautifully colored oxidation products is largely dependent upon the type of oxidizing agent present. Many gums give a light purple color due to the oxidases they contain. Blood gives a similar reaction. Ferric chloride reacts quantitatively. Silver nitrate gives a purple reaction accompanied by the reduction of the silver nitrate to metallic silver. Nitrites in sulphuric acid also give a color reaction. In many cases, however, if the oxidation is allowed to continue the colorless dioxypyrimidon results. An extraordinarily beautiful color is obtained when potassium persulphate is employed as the oxidizing agent. The reaction takes place in the cold and only after a long time does the color change to red and finally disappear. By means of this reaction small quantities of pyrimidon may be detected in antipyrine. The reaction works well on a slide. A small quantity of the material is suspended in a drop of water and a few small crystals of potassium persulphate added. In the presence of pyrimidon the crystals quickly surround themselves with a zone of purple. 0.5% of pyrimidon may thus be detected in antipyrine.—M. WAGENAAR *Pharm. Weekblad*, 72 (1935), 564 (E. H. W.)

Rauch-Schnee are small, white, odorless and tasteless tablets used for practical jokes. A tablet inserted in a cigarette or cigar produces by the glowing flame snow like flakes in the air. Chemical investigations reveal it to be identical with a substance commercially known as metaldehyde, a polymer of acetaldehyde. Physiologically, it is stronger than paraldehyde in action.—H SOMMER *Pharm Zentralh*, 76 (1935), 150 (E V S)

Sugars—Chemical Methods for Reducing Comparison of Values for copper dextrose equivalents as determined by titration of the copper with thiosulphate and by titration with dichromate using ortho phenanthroline as a colorimetric indicator (a modification of the Jackson Matthews electrometric method) respectively when compared with the Munson and Walker table values, showed good agreement except at higher concentrations of dextrose.—R F JACKSON and EMMA J McDONALD *J Assoc Official Agr Chem* 18 (1935), 172 (G S W)

Thallium—The Detection of Alkaloidal Reagents VII Being monovalent and trivalent, thallium forms two series of compounds. In general the thallic compounds are unstable. Commercial thallium compounds used for cosmetics, medicinal and rodenticidal purposes are almost entirely thallic. In the flame, compounds dissociate, liberating thallium which gives a characteristic green color and spectrum and if the flame strikes a cold surface a brown mirror is formed. In the Marsh apparatus the stain is similar to that produced by arsenic but it gives a yellow color with iodine and is insoluble in ammonium sulphide. Spectroscopic studies show characteristic lines. A detailed search of the literature has been made and the more promising reactions have been studied. Detailed results are arranged in two tables, one for thallic and one for thallic. These tables show reagent, color of solution, color of precipitate, precipitation threshold, mg Tl/cc and literature references. Ninety reagents were tried. An extensive list of references is appended.—JAMES C MUNCH and JUSTUS C WARD *J Am Pharm Assoc* 24 (1935), 351 (Z M C)

TOXICOLOGICAL CHEMISTRY

Arsenic—Triple Poisoning by A detailed description and discussion of 3 cases. In the first the subject survived administration of repeated doses extending from Dec 26 1929, to Feb 1, 1930, it led to suspicions being aroused in previous deaths and examination in Feb 1930 of two corpses buried in 1922 and 1929 respectively, clearly revealed the presence of arsenic in quantities sufficient, when taken in connection with the known clinical history of the cases to furnish proof of death by arsenic poisoning.—FONZES DIACON, GRYNFELT, RIMBAUD and CAVA LIE *Ann Med Legale Criminol Police Sci*, 15 (1935), 28-52 (A P C)

Thallium—Two Cases of Murder by Two cases are described in which death of a 48 year old woman and a 40 year old man respectively was produced by 1 to 3 tubes of Zehopasta (a rat poison) containing 0.909 to 2.728 Gm of thallium sulphate. Autopsy revealed in both cases the presence of thallium, estimated at 1.6215 Gm of the sulphate in the body of the woman and 1.332 Gm in the body of the man. It is concluded that gastrointestinal with polyneuritic symptoms and trophic disturbances of the hair should lead to a suspicion of thallium poisoning, and that it would appear as if the medicament preserved the body.—H KRSEK *Cas Lek Cesk*, 14 (1934) 40, through *Medico Legal Criminol Rev*, 2 (1934), 372 (A P-C)

PHARMACOGNOSY

VEGETABLE DRUGS

Drugs—Brazilian, in World Commerce The author discusses drugs derived from the Brazilian flora. Many hundreds are used domestically but only a few are exported. Among the latter the most important are *Anda-Assu* (*Euphorbiaceae*) yielding an oil similar to castor oil, having laxative properties. *Araoba* (*Papilionaceae*) in the form of Goa powder and used principally for the production of chrysarobin. *Canella*. Several Brazilian trees are called by this name, the exported bark however being that of *Nectandra amara*. *Copaiba Balsam*. This is yielded by several trees, the exported product often being a mixture derived from several sources. Mixing is usually done in the city of Obidos. *Elemi*. Several resins are known by this name among them the true elemi (*Bursera leptophloeos*), hard elemi (*Protium sp*) and bastard elemi, a yellow elemi coming from the *Guttiferae*. *Guarana* is prepared from the seeds of *Paullinia sorbilis*. About 1200 to 1500 Kg are used for domestic pharmaceutical purposes and about 15 000 go into the manu

facture of refreshing drinks *Ipecac* Both the true root (*Uragoga Ipecacuanha*) and that of *Richardsonia brasiliensis* are gathered. These are closely related plants. *Jaborandi* is yielded by *J. jaborandi* *J. pinnatifolius* and *J. spicatus* *Kopal* Most of the Brazilian *kopal* is exported to North America. *Koto* The name signifies anti diarrhoea which fact probably accounts for the appearance of several barks on the market. The true bark comes from *Ocotea argyrophylla*, *Nectandra elaeophora* and *Bracteanthus glycyarpus*. *Marapuama* the source of which are members of the Genus *Ptychopetalum* (*Oleaceae*). The extract of the root and stem bark has recently been shown to be beneficial in hookworm treatment. Most of it is exported to Argentina and Japan. *Sandal Oil* This is not an official oil but considerable quantities are produced, some 12,000 Kg being used in the perfume industry. *Tayuyi* under which name are known several roots of plants belonging to the Genus *Trianosperma* (*Cucurbitaceae*) used as antisiphilitics. The fatty oil of these plants is a laxative. *Tonka Beans* Five varieties are known but only two *Diplazis odorata* and *D. polyphylla* are used for the production of coumarin, the others being used for fixed oil.—FRED W. FREISE. *Der Tropenpflanzer* (1934) 469 through *Pharm Weekblad*, 72 (1935), 470 (E. H. W.)

Ergot—Russian All published information about Russian ergot has been about commercial supplies which are usually in a damp and moldy condition. In the fall of 1934, a number of specimens, cured as our Pharmacopœia specifies were received directly from Russia. Differences observed among the samples were of minor importance. The important question of differences relates to the color of the fractured surface. That of Spanish ergot is white. Food and drug officials have discontinued admission of damaged ergot with pink fracture. How Russian ergot of commerce came to be changed can only be conjectured. In the author's opinion somewhere from producer to importer it has been moistened to increase its weight. Aside from fracture color and odor official ergot shows little difference from that of Spain and Portugal. Externally it is not quite so dark. In general the grains are a little smaller and more slender. A table shows the sizes. A striking difference shows in the powders the Russian powder being blackish the Spanish light brown. The following conclusions seem clearly established. 1 The normal fracture color of all ergot is white. 2 The purple fracture color that has been commonly seen in Russian ergot is the result of decomposition caused by exposure to dampness and resulting putridity. 3 The specification by the U. S. P. Revision Committee of pink color in the fracture of ergot is the result of the former prevalence in our drug market of such decomposed ergot. 4 At the present time, the Russian ergot in the American market is in general of sound quality and exhibits a white fracture color. 5 All reference to pink fracture should be eliminated from the U. S. P. description of ergot. 6 Whatever method of bio assay may be adopted should be based on tests made with ergot of white fracture. Tests that have been made with the deteriorated ergot of pink fracture should be scrapped. All the specimens have been preserved and may be seen at the New York College of Pharmacy and also a sample of that now on the market in New York.—H. H. RUSBY. *J. Am. Pharm. Assoc.*, 24 (1935), 382 (Z. M. C.)

Plantago—Botanical Sources of Drugs Derived from the Genus The literature dealing with the *Plantago* species is briefly reviewed and anatomical differences are illustrated. All commercial samples of *Ispaghula* were found to consist entirely of *P. ovata* Forsk. no seeds of *P. amplexicaulis* being found. Commercial samples of "Psyllium" may consist of *P. arenaaria* or *P. lanceolata* in addition to *P. psyllium*. No *P. Cynops* seeds were found in the "Psyllium" examined. "Bartung" or "Barhand" consists of seeds of *P. major* and is widely used in the East.—E. W. SKYRME. *Quart. J. Pharm. Pharmacol.* 8 (1935), 1-12 (S. W. G.)

Strophanthus Emuni—Seeds of The seeds of *S. emuni* are apparently similar in their pharmacological action to those of *S. kombe* and the tincture and mixture of glycosidal principles obtained from them also appear to be similar pharmacologically and chemically. The inclusion of *S. emuni* in the Brit. Phar. is recommended. Reports of chemical, pharmacological and clinical tests are given.—BRITISH PHARMACOPŒIA COMMISSION. *Quart. J. Pharm. Pharmacol.*, 8 (1935), 61-70 (S. W. G.)

Tree Barks—Hygroscopicity of With regard to the sorption of moisture the air dry barks of *Cinchona succiruba*, toon (*Cedrela toona*), jaman (*Eugenia, jambolana*) and mango (*Mangifera indica*) are similar to wood. The maximum sorption at saturation humidity was 22-23%. The results were not affected appreciably either by presoaking the bark or by drying it to constant weight at 100°. The moisture content of barks should be determined before they are used in the

preparation of extracts and tinctures—S N KAPUR and D NARAYANAMURTI *Indian Forester*, 60 (1934), 702, through *Chem Abstracts*, 29 (1935), 3463

PHARMACY

GALENICAL

Distilled Water, Sterile—Preparation of, in a Vacuum If a water which is in itself nearly germ free, is distilled in a sterilized apparatus under reduced pressure and at only 48°, the distillate will be sterile. If, however, a contaminated water is used, some organisms will be found in the distillate. The construction of the apparatus has some bearing upon the sterility of the distillate under reduced pressure. The arrangement must be such as to prevent drops of contaminated water from being carried over mechanically. The "Sikotopf" apparatus either with or without vacuum produces a distilled water meeting the chemical tests of the Swiss Phar V, but one which cannot be relied upon to be sterile if reduced pressure is used. The apparatus described by Vuillemin will produce a chemically pure and at the same time sterile water at ordinary temperature at a very low cost.—J THOMANN and A KALIN *Pharm Acta Helv*, 10, (1935), 96

(M F W D)

Fluidextract of Thyme and Its Preparations Studies were made in which 1 Kg of drug was moistened with 50 Gm glycerin 75 Gm alcohol and 150 Gm water and then percolated, and the *pH*, dry weight (according to Peyer) and thymol content were determined. The following extracts were prepared (1) with 70% alcohol—bright brown, clear, transparent, remained clear on standing, *pH* 5.18, dry weight 1.49, thymol 0.0524%, slight turbidity with 5 parts of water. The syrup with 5% extract is clear, weakly opalescent, bright brown, has a distinct thymol taste, *pH* 5.20, with 10% extract it is more strongly opalescent, no sediment after long standing. (1a) An extract prepared according to the D A B VI by the addition of ammonia water and after filtering was dark brown, not transparent, deposit formed after 3 days, *pH* 8.86, dry weight 10.12, clear with 5 parts of water, thymol content 0.0475%, 10% syrup was clear, *pH* 5.8, thyme taste weaker than (1). (1b) An extract prepared by adding 20 Gm to the moistening liquid was green brown, turbid, deposited greatly *pH* 8.5, dry weight 10.1%, turbid with 5 parts of water, green flakes separating thymol content 0.0503. The 10% syrup was green and turbid separated into 2 layers (a clear brown layer and an upper green turbid one) *pH* 8.01. (3) An extract prepared by moistening the drug with ammonia water and then percolating with a mixture of 340 Gm of alcohol and 660 Gm of water had a dark brown color and was clear. After standing it formed a slight sediment, *pH* 5.5–6.71, dry weight 14.1, thymol content 0.0321%, clear with 5 parts of water and yielded a 10% syrup with *pH* 5.71. (4) An extract prepared by moistening the drug with a menstruum omitting the ammonia water and then percolating was clear with a red brown color, *pH* and had 5.21, dry weight 14.1% thymol 0.0330%, clear with 5 parts of water, the 10% syrup was clear and had *pH* 5.20. The syrups from (3) and (4) were much darker than those from (1) and (1a) but did not have the characteristic taste of thyme drugs. (4a) Extract (4) was treated with ammonia according to the D A B, filtered and the filtrate had a dry weight of 12.2% and a thymol content of 0.0302%. The residue on the filter was dried, partially dissolved in cold water, yielding a slightly turbid solution with boiling water and gave a test for thymol indicating that not only coloring matter but also active constituents were precipitated. (5) The preparation made according to the Swiss Phar yielded a fluidextract which was at first turbid and then settled *pH* 5.2, after neutralization 5.7, dry residue before filtering 16.11%, after filtration 14.8%, thymol content before filtration 0.032% and after filtration 0.031%, clear with 5 parts of water, the 10% syrup had a *pH* 5.41.—W BRANDRUP *Apoth Ztg*, 50 (1935), 293–294

(H M B)

Hydrogen Peroxide—Stabilization of, Especially by Acetanilid Höll finds that 3.1% hydrogen peroxide solution stabilized with 0.1% acetanilid was almost unchanged (3.05%) after 1½ year, 2.9% after 1 year. A 15.15% solution after 4 months contained 14.3% hydrogen peroxide and after 6 months 13.8%, without preservative it contained after 6 months 6.3%. However, acetanilid is decomposed in a short time by water giving nitrobenzene which is recognized by its odor and by the usual tests. The change occurs in the 3% solution in 1–2 months and in the stronger solution in a few weeks. Since the nitrobenzene is a poison acetanilid should not be used. Phenacetin is not decomposed at ordinary temperature even after many months by concen-

trated hydrogen peroxide solutions and a 15.2% solution treated with 0.05% phenacetin contained 14.5% hydrogen peroxide after 4 months. The stabilizing action of luminal, veronal, salicylic acid and sodium hypophosphite is much less. Experiments show that Nipagin M (0.1%) is the best of all stabilizers since 3% solutions showed no change after 4 months and 15.2% solution decreased to 14.8%. —*Apoth. Ztg.*, 50 (1935), 252 (H. M. B.)

Lugol's Solution The following formula is suggested as a uniform standard. Potassium iodide 2 Gm, iodine 1 Gm and water 20 cc.—E. BOLTANSKI *Presse med.*, 43 (1935), 292, through *Chem. Abstracts*, 29 (1935), 3464

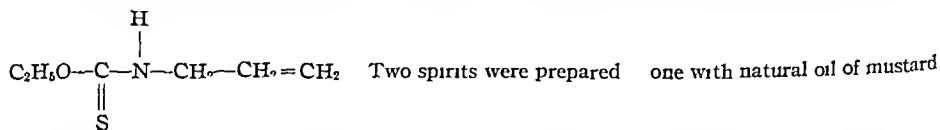

Ointments—Structure of Ointments can be classified as fatty waterless (I), fatty aqueous (II) and those containing no greasy substances (III). I form complicated multiphase systems when mixed with solid drugs. Pharmacologically they are protective salves, being impermeable to water and having a cumulative but slow action. II act much more strongly than I and may consist of an emulsion of oil in water or of water in oil or a mixture of an ointment and an emulsion. Pharmacologically they exert a cooling action as do also "quasi emulsions" obtained by addition of water to a solidifying fat. III are composed of swollen lyophilic colloids containing various drugs in a dispersed state.—M. GATTY, KOSTIAL and B. KAMIENSKI *Wiadomosci Farm.*, 61 (1934), 711, through *Chem. Abstr.*, 29 (1935), 3115

p_H —Pharmaceutical Study of The paper first considers formulation of p_H , showing how equilibrium exists, the small extent to which water dissociates, that pure water or a neutral aqueous solution is a 1/10,000,000 normal solution of both H-ions and OH-ions. Formulation of buffer capacity is not discussed except to explain the unit adopted by Van Slyke which is the differential ratio $\frac{dB}{d(p_H)}$ and which is used in adjusting pharmaceutical preparations to specified p_H values.

The formulation of electrode potentials is discussed and the fundamental equation for converting electrode potentials to hydrogen-ion concentrations given. The history of methods is traced with references to a number of men and the contributions they have made. Most drugs can be put into two groups: those having maximum stability at p_H 7 and those having maximum stability very near p_H 5. Stability in absence of acidity or alkalinity is easily understood but stability at p_H 5 must be explained on the basis of hydrogen ion catalysis. This the author does. Bronsted has developed a mathematical conception of hydrogen-ion concentration and a new definition of acids and bases. Though electrolytes exert considerable influence upon both the p_H and the stability of solutions, the fundamental effect is not understood. Electrolytes that increase acidity of acid solutions are named. Sulphates decrease it. The action of univalent or bivalent cations is mentioned. Under the heading "physiological p_H ," the reaction of distilled water is discussed, the difficulty attached to getting it and keeping it near p_H 7 even when stored in Jena ampuls. Fleisch's method for preparing a stable nutritive solution of physiological p_H is given. A number of other solutions are discussed. Sterilization of cocaine hydrochloride increases acidity but if buffered to a weakly acid reaction by Na_2CO_3 and NaH_2PO_4 or NaH_2PO_4 and Na_2HPO_4 , the p_H will remain stable during sterilization. Solutions of procaine hydrochloride can be stabilized in a similar manner. Morphine hydrochloride, novocaine, stovaine and atropine sulphate, benzyl alcohol, strophanthin, all call for special treatment. Previous workers have reported the change in p_H by sterilization of the following pharmaceutical products: dextrose, glycerophosphate compound, magnesium sulphate, physiological salt solution, procaine, procaine and epinephrine, all more acid; iron cacodylate less acid; mercurochrome, sodium salicylate, more alkaline, no change in sodium cacodylate, sodium iodide and salicylates with colchicine. A general method suggested by Robertson and others, for maintaining stable p_H during sterilization and which will remain stable for 2-3 weeks is given in detail. In ophthalmic therapy the adjustment of p_H is of considerable importance. The results of an investigation by Gifford and Denton are summarized. Since lacrimal secretions are about p_H 8, an acid buffer solution is prepared from boric acid and potassium chloride, so as to have a p_H of 5.5. An alkaline buffer solution which is less irritating and more suitable for atropine homatropine, physostigmine and pilocarpine is prepared by adding 0.20M solution of sodium carbonate to the acid buffer solution. How to handle phenacaine, atropine, homatropine, physostigmine, pilocarpine, zinc sulphate, sodium fluorescein, metaphen and butyn is reported. A table of p_H values for ophthalmic preparations determined by Gifford and Denton is given. The relation of p_H and toxicity is discussed with reference to alkaloids. Cranc's statement that the toxicity of alkaloidal salts is dependent

upon the degree of hydrolysis is explained. Hydrolysis curves are shown and a table comparing p_H and percentage of hydrolysis. Mayeda used cinchona alkaloids to verify his mathematical results and concluded that 'the biological action of cinchona alkaloids is dependent entirely upon the amount of alkaloidal base freed by hydrolytic dissociation which in turn is a function of the p_H and only the free quinine base is the bearer of biological action'. In general, experimental work with alkaloidal salts used as local anesthetics indicated increased biological activity when a greater amount of alkaloidal base is freed by dissociation. Considerable work has been done on the effect of p_H on the germicidal action of soaps. Preservative action of acids and bases is largely a function of hydrogen- and hydroxyl ion activity. It has been concluded that undissociated weak acids rather than the ions are the preservative agents and this agrees with the statement that undissociated molecules penetrate into protoplasm more readily than ions do. Preservatives in pharmaceutical preparations have been studied by a number of people and reports made for lactic acid, sugar, salt. Insulin itself has a toxic effect. Attention is directed to the reports about the influence of p_H upon mercuric chloride solutions, upon the antiseptic actions of phenyl substituted acids from benzoic to ϵ -phenyl caproic upon potassium iodide and sodium iodide solutions. Tschersch and Fluck investigated the instability caused by acacia. They found that it could be rendered inactive. Work by Krantz and associates is also reported. The stability of gelatin emulsions according to Friedman and Evans is dependent upon the p_H . Enz and Jordan investigating emulsification of alkaloid containing preparations found that the statement that 'emulsions are less apt to form in strongly acid or alkaline solutions than those which are neutral' is true only in specific instances. Numerous pharmaceutical colloids represent the two practical classes. Bogue showed that physical properties of colloids were a minimum at a p_H corresponding to the isoelectric point. Tyndall and Kraemer carried this study further. Considering p_H and stability of complex products of biological origin the author discusses proteins most of which do not require stabilization but general principles concerning their decomposition can be applied to the problem of stabilizing toxins, antitoxins and insulin. Reference is made to Northrop's work on gelatin, Svedberg's and associates on proteins in general, egg albumen, hemocyanin, other workers on the hydrolysis of casein in acid solution, the stability of toxins and lysins, tetanolytin, citrins and cholesterolins. Studies on hormones are cited. Experimental work on the stability of vitamins is shown by a table giving temperatures, time in hours, p_H and percentage of decomposition. The relation of activity of enzymes and p_H are not considered except to give a number of references. Each enzyme has an optimum p_H and changes in activity with changes in p_H are related to the state of ionization of the substrate and the enzyme. Pepsin and trypsin are briefly considered.—FREDERICK F JOHNSON *J Am Pharm Assoc*, 24 (1935), 397 (Z M C)

Spiritus Sinapis Swiss Phar V—Stability of Allylisothiocyanate the active ingredient of *Spiritus Sinapis*, reacts slowly on standing with ethyl alcohol to form allyloxythiourethane

and one with synthetic oil. Samples of each were stored at a temperature of 17° to 19° in daylight and in the dark. The allylisothiocyanate was determined on the day of preparation by the iodometric method of the Swiss Phar V. However, this method determined not only allylisothiocyanate but also allyloxythiourethane. To obviate this difficulty, advantage was taken of the fact that the latter compound adds iodine directly in acid solution while the former requires an ammoniacal medium. By subtracting the number of cc of 0.1N iodine used by the allyloxythiourethane from the total number used in the determination of the allylisothiocyanate plus allyloxythiourethane, the amount of unaltered allylisothiocyanate was determined. The four preparations were all assayed on the same days. The results were tabulated for a period of 247 days and they showed that *Spiritus Sinapis* must be freshly prepared as the pharmacopœia requires. Allyloxythiourethane, as a rubefacient, is valueless as a comparison of the therapeutic activity of a fresh and an old spirit showed. The stability is little affected whether natural or synthetic oil is used or whether the spirit is stored in the light or dark. The monograph of the Swiss Phar should contain a qualitative test for the presence of allyloxythiourethane.—J BUCHI *Pharm Acta Helv*, 10 (1935) 90 (M F W D)

PHARMACOPŒIAS AND FORMULARIES

British Pharmaceutical Codex 1934 An extensive review of the new Brit Phar Codex with detailed discussions of included material which has been developed in recent years. A list of specialties stating the composition, therapeutic usage, manufacturer and agent is given in the new Codex —MARG VAN HAUWAERT *J pharm Belg*, 17 (1935), 37, 61, 83, 98, 115, 169, 185, 203, 241, 261, 293, 307, 325 (S W G)

Homeopathic Dispensatory—New Methods of Preparation and Assay of The methods of preparing essences, tinctures, solutions, and powder dilutions of plants, animal products or minerals according to the homeopathic regulations are explained. The essences are prepared from the fresh plants. Plants free from camphor-like oils or resins are pressed until 60% of their sap is obtained, an equal volume of alcohol (90%) is added, and after standing for a period of time filtered. Plants yielding over 70% of sap are macerated for 14 days in alcohol (90%) equivalent in volume to sap content then pressed and filtered. Plants containing ethereal oil resins or camphors, and yielding less than 60% of sap are first tested for sap content, then sufficient alcohol is used to prepare the essence, usually a 1:3 dilution. The preparation of tinctures depends upon the nature of the drug. Fifty various types of tinctures are prepared from fresh animal material, the strength being 0.01 or 0.1. Acids are diluted ten times (D 1). Powder dilutions are prepared by repeated triturating and sieving of the materials. The diluents used are either aqueous or alcoholic media or milk sugar. The power of dilutions is indicated in tenths (D) or hundredths (C). The specific gravity and capillary analysis on filter paper or combined with luminescence analysis are also determined —KONRAD SCHULZE *Pharm Zentralh*, 76 (1935), 114 (E V S)

NON OFFICIAL FORMULÆ

Antacid Preparations Many of these preparations on the market are mixtures of soluble and insoluble alkaline salts with digestives such as pepsin, pancrease, diastase and flavored with peppermint, cinnamon, anise and menthol. The following are formulas of this type: (1) Precipitated calcium phosphate 9%, precipitated calcium carbonate 10%, magnesium oxide 20%, sodium bicarbonate 30%, bismuth subnitrate 20%, powdered sugar 20%, oil of peppermint 1%. Rub up the oil with the chalk and mix the rest of the ingredients with it thoroughly. (2) Magnesium oxide 25%, sodium carbonate 25%, sodium bicarbonate 25%, lactose 20%, pepsin 5%. (3) Bismuth subnitrate 15%, magnesium carbonate 20%, magnesium oxide 20%, sodium bicarbonate 19%, borax 3%, milk sugar 20%, pepsin 3%. (4) Sodium bicarbonate 20%, powdered ginger marc 3%, powdered rhubarb 5%, magnesium oxide 25%, magnesium carbonate 20%, bismuth subnitrate 20%, pepsin 2%, powdered sugar 10%. (5) Magnesium hydroxide 15%, magnesium oxide 15%, magnesium carbonate 15%, bismuth subnitrate 20%, sodium bicarbonate 13%, powdered sugar 20%, peppermint 2% —ANON *Drug and Cosmetic Ind*, 36 (1935) 550, 621 (H M B)

Cosmetic Formula Ingredients and method of manufacturing a hair oil formula of lanolin and mineral oil are cited —ANON *Arch Pharm og Chemi*, 42 (1935), 186 (C S L)

Hair Lotion The following composition is given: Alcohol 420, camphor 15, ammonia 22, oil of turpentine 40 and decoction of camomile 415 Gm —HENRI FAGNY *Fr Pat*, 776,966 (Feb 8 1935) (S W G)

Hair Tonics These preparations are divided into three classes: (1) those designed to prevent baldness, including those intended to "cure" baldness, (2) astringent intended to restrict excessive oiliness and scalp perspiration and (3) those designed to stimulate the scalp and dress the hair. No tonic is known which will prevent or cure baldness but in some cases can help to restore hair which is lost because of disease by killing bacteria on the scalp and by stimulating the circulation of the blood through the area. Stimulating tonics are also of value when baldness is caused by wearing excessively tight hats or by improper care of the scalp. Essentially most hair tonics consist of (a) solvents such as water, alcohol, glycerin, kerosene, chloroform, (b) counter irritants as cantharides, formic acid, capsicum, diethylphthalate, (c) conditioners as castor oil, sulphonated castor oil, (d) dandruff removers as quinine arsenite, potassium arsenite, potassium sulphate, (e) antiseptics as Fowler's solution, Carrel Dakin solution, formaldehyde, benzoic acid and its esters, phenol, resorcin, resorcin monoacetate etc, (f) foaming agents as saponin, powdered soap, tincture quillaja, (g) detergents as sodium lauryl sulphonate, sodium cetyl sulphonate, soap

sulphonated oils The following formulas are offered (1) Castor oil, odorless 18%, chloral hydrate 2%, alcohol 79.5%, perfume 0.5% Dissolve the chloral hydrate in the oil, add the perfume and alcohol, filter This is useful for dry hair and scalp and to impart a lustric to the hair (2) Potassium arsenite 0.2%, deodorized kerosene 74%, alcohol 20%, perfume 0.8% ethylene glycol 5% Dissolve the salt and perfume in the alcohol, add ethylene glycol and kerosene and mix This product is excellent for dandruff and should be dispensed with a "shakc" label (3) Fowler's solution 25%, alcohol 30%, glycerin 5%, saponin 0.5%, water 39%, perfume 0.5% Dissolve the saponin in a small amount of water, add glycerin and alcohol, mix add water and Fowler's solution This tonic is recommended as an antiseptic for treatment of dry scalp and dandruff and is a good dressing (4) Chlorothymol 0.1%, tincture of capsicum 4%, quinine arsenite 0.2%, alcohol 75%, castor oil 20%, perfume 0.7% Dissolve the chlorothymol and quinine salt in alcohol, add perfume, tincture and oil This tonic is an excellent antiseptic for dandruff and a good dressing (5) Tannic acid 4%, formaldehyde 0.2%, alcohol 60%, water 35%, perfume 0.8% Dissolve the acid in alcohol, add the other ingredients, mix and filter This is a good antiseptic astringent tonic for oily scalp and dandruff (6) Quinine arsenite 0.2%, tincture cinchona 10%, tincture quillaja 4%, quinine 0.5%, alcohol 60%, perfume 0.3%, water 25% Dissolve the quinine and its salt in alcohol add the remainder of the ingredients mix filter —*ANON Drug and Cosmetic Ind* 36 (1935) 553-554 (H M B)

Mouth-Wash Powders The powders contain a stabilized oxygen-yielding compound mixed with a silver-containing compound and preferably also an acid substance The various substances which may be used are given The following example is given Dehydrated sodium perborate 30 silver salt of *p* hydroxybenzoic acid 16 and tartaric acid 11.25 Gm —*DEUTSCHE GOLD UND SILBER SCHEIDANSTALT VORM ROESSLER* Brit Pat, 421 692 (Dec 28, 1934) (S W G)

Sage Oil in Perfumery and Cosmetics Properties and uses are discussed Because of its disinfecting power the oil may be used in the following types of toilet vinegars (1) alcohol (90%) 1000 parts, glacial acetic acid 100, acetic ether 20, water 300, lavender oil (terpeneless) 15 bergamot oil (terpeneless) 5, sage oil 3, (2) water 7000 parts, alcohol 3500 bergamot oil 30 citronella oil (terpeneless) 3, oil of orange 10, sage oil 25, lavender oil 5, oil of neroli 5 50% sage infusion 500 Allow to stand for 24 hours add tincture of benzoin 60, and tincture of tolu 60 Shake and add wine vinegar 2000 parts After 24 hours filter and add 90 parts of glacial acetic acid Finely powdered dried leaves of sage are of advantage in tooth powders and pastes, the drug as well as the oil is valuable as a deodorant in baths and in the form of a wine or tea is of value in healing abscesses and internally to counteract fevers and grippe —*A M BURGER Riechstoff-Ind*, 10 (1935) 61-63 (H M B)

Solar Shields—Comments on A discussion on the formation of sunburns and tans It appears that sunburn preventives should absorb strongly between 2950-3150 Å units to be the most effective The writer feels that when the label of a good sunburn preventive claims to promote tan it is not misbranding for by preventing burning and dermal injury, pigmentation is acquired faster and is deeper than in skins which have been burned —*L STAMBOVSKY Drug and Cosmetic Ind* 36 (1935), 551-552, 554 (H M B)

Tooth Preparations—Soaps and Soap Substitutes in The use of soaps is discussed The disinfecting power of soaps might be increased by the addition of Nipazol or Nipabenzyl Saponin from quillaja may be added in small amounts as well as Turkey Red oil and fatty alcohols —*J AUGUSTIN Riechstoff-Ind*, 10 (1935), 59-60 (H M B)

DISPENSING

Acriflavine Emulsion—Simple Formula for The emulsion may be prepared by dissolving acriflavine in equal parts of lime water and arachis or olive oil The formula is acriflavine B P 1 Gm, lime water B P 500 cc arachis (or olive) oil, B P 500 cc Dissolve the acriflavine in the lime water add the oil and shake thoroughly The preparation is highly antiseptic and is particularly useful in the treatment of wounds abrasions burns of lesser degree and scalds and in severe burns after preliminary treatment with tannic acid —*J WALKER TOMB Prescriber*, 29 (1935), 207 (S W G)

Dispensing Cabinet—Aseptic The dispensing cabinet described has the following advantages It may be swabbed with an antiseptic solution as it is made chiefly of glass, it may be completely closed when not in use, with a little practice it is as easy to work with the case as on

the open bench The dimensions are Base 36 in by $19\frac{1}{4}$ in, ends 21 in high, $18\frac{1}{2}$ in wide, 11 in high at front and sloping back at 60 degrees Four glass doors, 10 in by $9\frac{1}{4}$ in in size, slide between grooves in the lower brass rod and in a grooved brass strip on the base-board The wooden interior is enameled white and the brass rods are chromium plated The illustration shows the

case assembled with balance filtration apparatus and apparatus for filling ampuls by suction The flask on the left is a water trap leading to a filter pump —C GUNN *Pharm J*, 134 (1935), 327 (W B B)

Magnesium Oxide—Incompatibility of, with Sodium Bicarbonate When the above mixture was dispensed the sediment, at first diffusible, in a few minutes was diffusible only with difficulty, and in about two hours bunches of needle like crystals were formed on the sides of the bottle No evolution of carbon dioxide took place In order to ascertain the nature of the chemical changes that occur, one mole (42 Gm) of sodium bicarbonate was dissolved in 500 cc of distilled water and one mole (20 Gm) of heavy magnesium oxide was added A crystalline deposit formed in two days Eight grams of crystals were obtained A second batch of crystals was obtained on standing The crystals were sparingly soluble in water soluble with effervescence in dilute acids and were found to consist of a hydrated carbonate of magnesium A magnesium carbonate of similar composition was obtained by using two moles (84 Gm) of sodium bicarbonate dissolved in 1100 cc of water and one mole (20 Gm) of heavy magnesium oxide It is the formation of this crystalline hydroxy carbonate of magnesium which causes the sediment in the mixture to become indiffusible —N W WEST *Australasian J Pharm* 16 (1935), 182 (T G W)

Ointment Jars—Bakelite Recently, ointment jars made of bakelite have been offered for sale The authors obtained two makes of bakelite jars and tested them with regard to 16 different ointments They found that ointments containing pharmaceuticals having phenolic hydroxyl groups as resorcinol naphthol, etc, and ointments containing mercury compounds suffer changes on contact with bakelite They also found the particular makes of jars to be technically defective —BÜCHI and SCHENKER *Schweiz Apoth-Ztg*, 73 (1935) 239 (M F W D)

Papaverine Hydrochloride—Solubility of, in Presence of Certain Salts Papaverine hydrochloride was added in different amounts to a series of solutions of sodium bromide of concentrations from 5% to 30% With 5% solution of the bromide no turbidity was produced while with higher concentrations a precipitate settled out The precipitate was found to be papaverine hydrochloride Similar results were obtained with sodium chloride, potassium bromide ammonium bromide calcium bromide and potassium nitrate Magnesium chloride had no effect on the solubility of papaverine hydrochloride in the concentrations studied —E DEFRANCE *J pharm Belg*, 17 (1935), 393 (S W G)

Solvents for Therapeutic Substances Mixtures of betaine or its homologs with amides of lower fatty acids, with or without water are useful as solvents of substances slightly soluble in water. Phenylethylbarbituric acid may be dissolved in a mixture of acetamide 65, betaine 5 and water 30% to give a solution containing 10 Gm in 100 cc of solution. Other solutions are cited. Other substances may be added to the solvent mixtures. Solutions of albuminous and fatty substances were not prepared.—EGGOCHEMIA FABRIK CHEM UND PHARMAZEUTISCHER PRAPARATE PATZAU Austrian Pat., 140,431, Jan 25, 1935 (Cl 30f) (S W G)

Sucrose Octa-Acetate—Compulsory Use of, as Rubbing Alcohol Denaturant Regulations affecting manufacture of rubbing alcohol compounds issued by Bureau of Internal Revenue, Washington, involve the use of an entirely new denaturing material as from June 1st next, viz, sucrose octa-acetate. The formula for the new specially denatured alcohol is given. Sucrose octa-acetate is an organic acetylation product, being a white non-hygroscopic powder having an intensely bitter taste. It shall have a melting point of not less than 69.0° C and not more than 72.0° C. Other properties are also given. The formulae of rubbing alcohols are discussed.—ANON *Perf and Ess Oil Rec*, 26 (1935), 180 (A C DeD)

Tablets—Mean Deviation of Functions of Correlated Observations and of Uncorrelated Observations, as Applied to Development of formulae of correlation is set forth. It is shown how one takes account of the correlation between two variables when determining the mean deviation of a function of the two variables. A sampled group of tablets is then cited as an example as regards the relation of their weight, their content of chemicals and their percentage composition. In the case of a sampling from products made under identical conditions, it is to be expected that their weight and content of chemicals should show an absolute correlation, yet this may not be found in practice, while a correlation will be found between the weight and the percentage composition. This may be explained on the assumption that the moisture content of the tablet mass has altered by evaporation during the preparation of the tablets.—J P JACOBSEN *Dansk Tids Farm*, 9 (1935), 53 (C S L)

Zinc Oxide and Olive Oil—Mixtures of A study is reported of fifteen specimens of zinc oxide olive oil mixtures, prepared with zinc oxide of various qualities. The finer powdered the oxide used, the more solid the consistency of the olive oil mixture. Many dermatologists add lanolin to these formulas to gain such consistency.—E KARLING *Farm Revy* 34 (1935), 239 (C S L)

PHARMACEUTICAL HISTORY

Christ as an Apothecary A discussion of pictures portraying Christ as a member of this profession.—ANON *Pharm Post* 68 (1935), 165-170 (H M B)

Cosmetics—History of, in Recent Times Historical account covering the 17th and 18th centuries. Many interesting illustrations are offered.—A HAUENSTEIN *Riechstoff-Ind*, 10 (1935), 67-71 (H M B)

PHARMACEUTICAL EDUCATION

Pharmacognosy—The Teaching of Habitats in In learning habitats the average student associates the name of the drug and a geographical locality, chiefly by "brute memory." The best way to create desirable associations is to use geographical information along with discussion of the drug. This may be done by giving history, collection and commerce with topography of the region where it is found or cultivated. The Bible, the Travels of Marco Polo and other historical or travel books help to create interest. Pictures may be used or photographs, lantern slides along with commercial aspects make excellent combinations. Drug maps are very valuable helps. Maps of continents are better than world maps. The author uses them in laboratory manual the student writing drug names on his map. Knowledge of habitats is a minor part of pharmacognostical instruction but it offers a link in association between pharmacognosy and other knowledge and teachers should not overlook the value.—ELMER H WIRTH *J Am Pharm Assoc*, 24 (1935), 413 (Z M C)

Urinalysis—Teaching, to Students of Pharmacy Comments on Paper by Professor Antoine E Greene. A pharmacist should be able to assist the medical practitioner, so study of urinalysis should be an acceptable elective and if possible a required subject. In an analysis of

urine, as much emphasis should be placed on microscopic findings as chemical, though a bacteriological examination is only necessary occasionally. A correct interpretation of chemical findings requires microscopical examination. Experience has shown it to be desirable to give chemical and microscopical instruction at the same time or during the same semester. The same instructor should teach both, but if that is not possible, the departments should cooperate. As an example of need for combined examination, presence of albumin may or may not be significant. In warm weather, samples in transit and not properly preserved often show abundant bacteria from which it is possible for sufficient albumin to be extracted to give a positive chemical test for albumin. Uric acid, triple phosphates, calcium oxalate, leucine, tyrosine and cystine are revealed microscopically by type of crystals. It is common to speak of the chemical test for blood but it is a test for hemoglobin and does not reveal whether there is a hemoglobinuria or a hematuria. Hematuria indicates a pathological condition of the genitourinary tract, hemoglobinuria is usually the result of abnormalities outside the genitourinary tract. Hematuria, in addition to giving positive chemical test, will be indicated by finding unruptured red corpuscles, microscopically. Pus cells, casts and mucus will be found by microscopical examination when chemical tests are negative. It is difficult to get all important data into one course. A number of notations were added to those in the course outlined by Professor Greene.—LOUIS GERSHENFELD *J Am Pharm Assoc*, 24 (1935), 417 (Z M C)

Urinalysis—Teaching, to Students of Pharmacy The author believes that urinalysis should be retained in the curriculum of pharmacy, at least as an elective, equivalent in hours and credit to the biochemistry outlined in the Syllabus. The course should teach the technique of routine examination of normal and pathological urines. Time is insufficient for microscopic or bacteriological analysis. The paper continues with some details of how the course is given at Howard University, some special means of creating interest on the part of the students and concludes with an outline of the course.—ANTOINE E GREENE *J Am Pharm Assoc*, 24 (1935), 166 (Z M C)

MISCELLANEOUS

Dentists and Pharmacists—Professional Relations between Suggestions for the improvement of. Though dentistry has been practiced for centuries, dentistry as a distinct profession dates from 1839 when the Baltimore College of Dentistry, the first dental school in the world was established. As the profession has advanced it has been increasingly exploited by manufacturers. Use of preparations about which they know little is unconsciously encouraged by dentists because much prescribing is done by word of mouth. They are inadequately trained in prescribing and there is constant pressure by detail men. The American Dental Association is aware of this condition and has established a Council on Dental Therapeutics. The purpose of the Council is to acquaint the profession with useful drugs and their preparation and to expose useless or unacceptable things. These findings are reported each month in the *Journal of the American Dental Association* and they will be compiled in a book similar to the *New and Non Official Remedies of the American Medical Association*. Personal contact of individuals of both professions offer many opportunities for suggestions for prescriptions to take the place of proprietary articles. In most dental schools, students have little opportunity to prepare or combine drugs and dentists lack confidence in writing prescriptions. Since dentistry is becoming more of a preventive science and the need for laboratory tests will become greater as time goes on, this is in no way an encroachment on the practice of medicine. Pyorrhea is a case in point. A dentist should have a knowledge of the blood sugar before undertaking treatment. By having a white count and a granulocyte count it would be a simple matter to differentiate between Vincent's infection and granulocytosis. Postgraduate courses should be sponsored by pharmacy and dental schools. The men in pharmacy should be available to dental societies and other groups who need information about more efficient drugs.—C L WHITMAN *J Am Pharm Assoc*, 24 (1935), 392 (Z M C)

U S P and N F Publicity in a Retail Pharmacy—The Successful Application of The author explains some of the means of publicity adopted.—LAWRENCE S WILLIAMS *J Am Pharm Assoc*, 24 (1935), 395 (Z M C)

PHARMACOLOGY, TOXICOLOGY AND THERAPEUTICS

PHARMACOLOGY

Acetyl Beta Methylcholine—Action of, on Ventricular Rhythms Induced by Adrenaline
Acetyl beta methylcholine in man tends to counteract the effect of adrenaline on the rhythmic property of the ventricles —M H NATHANSON *Proc Soc Exptl Biol Med*, 32 (1935), 1297
(A E M)

Adonidin—Minimum Emetic Dose with The Magnus Hatcher method of biological determination by the cat can be used to determine *Adonins I* with the same security as with digitals The lethal dose for the cat is 0.476 mg/Kg It has a diuretic action —M F PASTOR, E E IMAZ and C GRIOT *Rev asoc med Argentina*, 46 (1932), 1515, *Anales asoc quim Argen tina*, 22, 219B, through *Chem Abstracts*, 29 (1935), 3466

Alcohol—Extent of Absorption of, at Various Intervals after Oral Administration The percentage of absorption is, after 1/4 hour 57.7%, after one hour 88.5%, after one and 1/2 hours 93.4% and practically complete after 2 hours —R N HARGER and H R HULPIEU *Proc Soc Exptl Biol Med*, 32 (1935), 1247
(A E M)

Amidopyrine—Effect of, on Leucocyte Count Rabbits, infected with the respiratory disease, snuffles, or with an acute intestinal disease characterized by diarrhea, loss in weight and death, developed a pronounced leucocytosis Large daily doses of a preparation containing amidopyrine and 5,5 diallylbarbituric acid (cibalgine) (I), 1-4 tablets, were given to rabbits of the following groups normal rabbits, infected rabbits and thyroidectomized infected animals Leucocyte counts were made on corresponding animals not receiving I The authors conclude that I does not diminish the number of leucocytes in the circulating blood of normal rabbits when given in large doses for 17 consecutive days The pronounced leucocytosis which occurs in rabbits with snuffles or gastrointestinal infection is not depressed by I, administered over 17-30 days Rabbits thyroidectomized 6 weeks previously and receiving I develop a leucocytosis in response to the infections comparable to that which develops in rabbits with thyroids intact Many differential counts were made from time to time of animals to which the drug was administered The percentage of granulocytes of the total leucocyte count was at all times within the range of normal variations Table —M M KUNDE, R P HERWICK A LEARNER and M STERNBACK *Proc Soc Exptl Biol Med* 32 (1935), 1121, through *Squibb Abstr Bull*, 8 (1935) A-725

Amytal—Effect of, upon Pilocarpine-Induced Submaxillary and Gastric Secretion Amytal causes a delayed shortening of the pilocarpine induced secretion The effect appears on the second day or later —MARY F MONTGOMERY *Proc Soc Exptl Biol Med*, 32 (1935), 1287
(A E M)

Bichromate—Skin Sensitivity to A case showing a high degree of specific sensitization of chromates is reported A definite skin reaction was obtained with 0.000,0033 Gm of potassium bichromate applied externally and with 0.000 000,0033 Gm on intradermal inoculation Attempts at passive transfer yielded negative results —C E HERCUS *Lancet*, 228 (1935) 985
(W H H)

Caffeine, Coffee and Decaffeinated Coffee—Effect of, upon Blood Pressure, Pulse Rate and Simple Reaction Time of Men of Various Ages These studies were made upon sixteen men who received coffee or caffeine plus decaffeinated coffee Decaffeinated coffee did not affect the reaction time Two mg of caffeine or the equivalent of coffee per Kg shortened the reaction time as compared with decaffeinated coffee in some individuals and lengthened it in others With doses of 3-4 mg of caffeine per Kg the initial reaction time was shortened as compared with the caffeine less coffee, but on the following day the reaction was frequently longer One to two hours after coffee (equivalent to 3, 4 and 5.5 mg of caffeine per Kg) the blood pressure was higher (5-10 mm Hg) and the pulse rate slower in some individuals, and faster in others, than the blood pressure and pulse rate after the decaffeinated coffee The changes in blood pressure and pulse rate elicited by coffee were more pronounced in the older men than in some of the younger ones —KATHRYN HORST and WILLIAM L JENKINS *J Pharmacol*, 53 (1935), 385
(H B H)

Colchicine—New Physiological Property of Intravenous injection of 0.05 mg epinephrine (adrenaline) (I) in a 16.5 Kg dog chloralosed, bivagotomized at the neck and subjected to artificial respiration, increased the carotid pressure 114 mg mercury and totally inhibited peristalsis for 87 seconds After the intravenous injection of 2.75 mg colchicine (II) per Kg in 4 successive doses,

the above dosage of I raised the carotid pressure 172 mm mercury and stopped peristalsis for 108 seconds. Experiments with another dog using larger doses of II up to 15.5 mg per Kg gave similar results. Thus II, like cocaine and several related substances, increased the motor and inhibitor effects of I on the whole animal.—R. HAMET *Compt rend soc biol*, 118 (1935), 1292, through *Squibb Abstr Bull*, 8 (1935), A-731.

Corynanthine—Antagonism of, to Epinephrine Tested on the rabbit's cornea, cocaine has one-half and corynanthine one-eighth the anesthetic activity of yohimbine. In chloralosed 10-11 Kg dogs intravenously injected with 35-60.5 mg of corynanthine hydrochloride, the intravenous injection of epinephrine provoked slight polypnea instead of apnea. In one case although the epinephrine was rendered slightly hypotensive by corynanthine it produced a transient cessation of respiration before slight polypnea, indicating that the respiratory effects are not exclusively dependent on the modifications of the blood pressure.—R. HAMET *Compt rend soc biol*, 118 (1935), 774, through *Squibb Abstr Bull*, 8 (1935), A-651.

Croton Oil—Action of Substances Isolated from The strongest active substance isolated from croton oil is croton resin. But since it is normally not present in croton oil it must be considered as an artificial product. The non-toxic basal substance is phorbol $C_{20}H_{30}O_6$. Acetyl phorbol, $C_{22}H_{32}O_{10}$ is a crystalline substance the activity and toxicity of which are very similar to that of the amorphous croton poisons. It stimulates the central nervous system, has a pressor effect on the blood pressure and stimulates the vagus of warm-blooded animals. In large doses it has a paralyzing action (narcosis of cold-blooded animals). In low concentrations it causes contraction of smooth muscles (vasoconstriction and peristalsis). The automatic centers of the frog's heart are paralyzed at an early stage.—R. BOHM, B. FLASCHENTRAGER and L. LENDLE *Arch expil Path Pharmacol*, 177 (1935), 212, through *Quart J Pharm Pharmacol*, 8 (1935), 152.

Digitalis—Assay of Preparations of, in Man Digitalis assay in frogs and cats is not absolutely accurate. The activity of digitalis preparations should be tested separately in each patient affected with heart disease by comparing the dose with that of *k* strophanthin found adequate in maintaining the proper heart conduction. The ratio thus obtained gives an accurate measure of digitalis potency and may be compared with values similarly determined in other cardiac cases. The digitalis preparation must be administered for a considerable length of time. The heart is found to undergo changes in response when its weakness has been improved by administration of digitalis. Disturbances in heart beat such as bigeminy and decrease in conduction are not signs of digitalis hyperdosage as previously supposed. They are not to be considered accurate measures of the intensity of digitalis action. The circulatory action of digitalis compounds is determined by the condition of the circulation. Once it has changed the status of the circulation digitalis subsequently reacts differently. Strophanthin is not useful as a basis of comparison with digitalis preparations in the non-congestive type of heart disease. Here, various preparations should be compared directly with each other, by the intravenous route. The activity of various digitalis preparations as assayed in 25 individuals is as follows: 0.3 mg *k* strophanthin intravenously is greater than 0.75 mg digilanid orally, 1.5 mg digilanid rectally equal to 0.8 mg digilanid intravenously, greater than 0.3 mg helleborein intravenously. 0.6 Gm digipurat orally, 3600 frog units convallaria orally less than 1 cc digalen intravenously, 0.3 Gm digitalis orally is greater than 6000 frog units convallaria orally and rectally greater than 3000 frog units orally. 0.8 mg Verodigen orally is greater than 3000 frog units convallaria orally, 0.8 mg digilanid intravenously is equal to 0.3 mg strophanthin intravenously, 0.7 mg digilanid intravenously corresponds to 0.25 mg strophanthin intravenously.—E. EDENS *Klin Wochschr*, 14 (1935), 414 through *Squibb Abstr Bull*, 8 (1935), A-577.

Digitalis—Potency of Oregon Conflicting evidence regarding physiological activity of digitalis is found by examination of the literature. It grows wild on the Pacific slope from Vancouver to California and report is made of a seasonal study of it in Oregon. Monthly collections of both first-year and second-year leaves during the spring and summer of 1932-1933. Tinctures were prepared according to U. S. P. directions and the tinctures were stored in a cool place. They were assayed by the official "one hour" frog method using frogs of the species *Rana pipiens*. An attempt was made to correlate physiological activity with seasonable glucosidal content by the proposed colorimetric method of Knudsen and Dresbach but there was difficulty because it seemed impossible to compare tinctures which were greenish with the standard ouabain solution which was dark yellowish. The following conclusions were reached: "the physiological activity of first

year leaves compared favorably with the second-year leaves, the activity of native digitalis plants under favorable climatic conditions would probably be above U S P standard, the one hour frog method is unsatisfactory chiefly because of the time element which has a tendency toward erratic results, observed only a slight difference in the susceptibility of frogs to cardiac stimulants through various seasons"—DONALD KUO CHIH LEE and ERNST T STUHR *J Am Pharm Assoc*, 24 (1935), 367 (Z M C)

Digitalis—Rectal Absorption of, in Cats Since digitalis frequently causes nausea and vomiting, when administered by mouth, administration by rectum has been suggested and preparations for use that way have been offered to the medical profession. A study was undertaken to determine what preparation is best suited to rectal use. In a preliminary experiment a de-alcoholized fluid extract was administered to two cats by rectum. There was difficulty in keeping the digitalis solution in the rectum because of the severe irritation but enough was retained to cause death in from 3 to 3½ hours. Five series ranging from 5 to 15 each were carried out to determine rate of absorption of different preparations. Results of each series are tabulated so that comparisons are readily made. Suppositories with powdered digitalis and with extract of digitalis in cacao butter base, suppositories with glycerinated gelatin alone and lastly a de-alcoholized tincture were used. The cats were kept under light anesthesia throughout. After 5 hours after administration of the rectal preparation standardized digitalis solution sufficient to cause death was introduced intravenously. Clinical reports highly recommend rectal digitalis therapy but findings in this investigation do not confirm those reports. Absorption was slow and small in amount, irregular and erratic. The most rapid absorption was observed when de-alcoholized tincture was used. Nausea and emesis occurred in the interval elapsing between the rectal administration and the intravenous administration in about half of the experiments but may have been due to the anesthetic. Autopsies disclosed considerable irritation and inflammation. The actual significance of these results will not be evident until the absorption rate following oral administration has been determined in the same manner. The rectal method should have more investigation before it is accepted as conventional.—W ARTHUR PURDUM *J Am Pharm Assoc*, 25 (1935), 374 (Z M C)

Digitalis—Studies on the Bioassay of III A New Diuretic Cat Method In toxic amounts digitalis has a peripheral constrictor effect on the blood vessels of the kidney in animals, which, taken with the weakening effect on the circulation, decreases output of urine (oliguria). Since digitalis has a cumulative action, oliguria should follow repeated administration of small doses and effect may be measured by measuring urine output at short intervals. Increase in toxic activity as shown by decreasing output of urine should serve as guide to rate and amount of administration in intravenous methods of assay and by indicating approach of death make possible a more accurate determination of minimum lethal dose than the continuous intravenous injection. The following experimental procedure was tried on the cat. Three tinctures were tested. The change from diuresis to oliguria was studied. Minimum lethal doses were determined and compared with those by other methods. Experimental procedure is given in considerable detail and a typical protocol of procedure and results is reported. Comparison of minimum lethal doses of the three tinctures are shown by table as well as the comparison of this method with four other methods. The assays corroborate observations made in the literature that cats vary in susceptibility to digitalis. Assays of one tincture were very uniform but the others showed large positive and negative variations. Variations in frogs and guinea pigs are not so important because large numbers can be used. In the new method the drug is not injected continuously and this should be an advantage because digitalis acts slowly making an accurate determination difficult if a rapid, continuous injection method is used. The constantly decreasing output of urine is more easily discernible than the heart changes ordinarily observed by auscultation in the usual cat method. Best results were obtained with cats weighing from 2 to 3 Kg, those above or below these weights showing wider variation in susceptibility. The wide individual variation in susceptibility to digitalis makes their value questionable since in practice only a few animals can be used. Results of dog and guinea pig assays agreed more closely with each other than with those of the cat method.—JAMES H DEFANDORF *J Am Pharm Assoc*, 24 (1935), 369 (Z M C)

Dinitrophenol—Effect of, on Heart The amplitude of contraction of the Straub frog heart and rhythmic frog heart muscle strips was irreversibly decreased by 1, 1,000,000 2,4 dinitrophenol (I) or 4.6 dinitro *o*-cresol (II). II was more toxic than I, its effect being apparent in concentra-

tions of 1 5,000,000 I in concentrations of 1 150,000 decreased the minute volume in the Starling heart lung preparation of a cat from 94.5 to 42 cc within 9 minutes. Again, II was more toxic, producing an immediate decrease in the minimum volume and in arterial pressure. Concentrations of 1 30,000 of II rapidly arrested the heart. With the average dose of 3-5 mg/Kg of I and 0.5-1 mg/Kg of II, the concentration of the drugs in the human body fluids is 1 220,000-1 115,000 and 1 320,000-1 660,000, respectively, concentrations definitely toxic to the heart preparations.—H. STAUB and K. MEZEY *Arch expil Path Pharmacol*, 178 (1935), 52, through *Squibb Abstr Bull*, 8 (1935), A-710

Drugs—Absorption of, through the Oral Mucosa Humans and dogs served as the experimental subjects in these tests. As compared with the effectiveness of subcutaneous administration, the ratios for a number of drugs were found to be as follows upon sublingual applications: sodium pentobarbital, 1, apomorphine, 2, strychnine, 4, atropine, 8, morphine, 10, dilaudid, 15 codeine, greater than 15. Adrenaline and insulin produced no distinct effects when administered sublingually even in large doses. There was close agreement between the results obtained in human subjects and dogs in the case of sodium pentobarbital, apomorphine, atropine, morphine, dilaudid and adrenaline.—ROBERT P. WALTON and C. FRANK LACEY *J Pharmacol*, 54 (1935) 61 (H. B. H.)

Drugs—Effect of Altitude on the Action of I Strychnine Report is made of an investigation whose purpose was to make quantitative studies of the variation in lethal doses and the speed of action, all variables except altitude being kept constant. Strychnine sulphate was used. In one series of experiments, one hundred tame rats were used, in the other, Columbian ground squirrels. The rats were purchased in Denver, and half of them sent to Hillsboro, Oregon. Feed was purchased in Denver and divided. Animals were held for three months to insure acclimatization. The poison solution was prepared in Denver and divided. The same technique of administration was employed. Room temperature, barometric pressure, relative humidity and character of weather were recorded. Conditions checked well, so barometric pressure was chief variation. Climatological comparisons are given in one table. Other tabulations showing detailed experimental results, correlations on the basis of probable errors of the averages, averages with survival evaluations included, significance of correlations and experimental results for Columbian ground squirrels—oral administration. The lethal dose for 100% of the rats tested was 12.50 mg/Kg at Hillsboro and 10.00 mg/Kg at Denver. Also 10/10 animals at Hillsboro died in 25 minutes after 4.1 minutes of the intermittent tetany while at Denver the figures were 15.0 and 4.0 minutes, respectively. The following conclusions were drawn: "1. A change in elevation of 5000 feet caused a 20% reduction in LD_{100%} and a 40% decrease in the T/D (time to death), following oral administration of strychnine as the sulphate to tame rats. 2. Statistical analysis shows the effects observed are not highly significant, ranging from 1-20 to 1-5000. 3. Inclusion of survivals by a percentage system of evaluation, causes the curves to approach the ideal. 4. Successive increase of elevation of 1000 feet produced a definite and fairly constant reduction in LD_{100%} of strychnine administered orally to Columbian ground squirrels. 5. Ground squirrels appeared to be more susceptible than rats to changes in elevation."—A. W. MOORE and JUSTUS C. WARD *J Am Pharm Assoc* 24 (1935) 460 (Z. M. C.)

Ergot—Biological Determination of Alkaloids of Ergot alkaloids can be readily determined on the basis of their antagonistic action to adrenaline. The rhythmic oscillations of surviving rabbit intestines are decreased by adrenaline and this effect of adrenaline is prevented by the alkaloids of ergot. As the reaction is reversible the same portion of intestine can be used two or three times. The effect of 2γ adrenaline was decreased 27.5% by 3γ ergotamine, 54.3% by 4.5γ, 57.4% by 5γ, and 71.5% by 7.5γ ergotamine. Sensibamine separated from Hungarian ergot is as strong as ergotamine.—B. ISSEKUTZ and M. LEINZINGER *Magyar Gyógyszereszlud Társaság Értesítője*, 11 (1935), 171, through *Chem Abstr* 29 (1935), 3775

Evipal—Hypnosis, Anesthesia and Toxicity These studies were made upon rabbits and rats to which the drug was given, with but one exception intraperitoneally. The optimal hypnotic dose was found to be 50 mg per Kg for rats. The optimal anesthetic dose is 100 mg per Kg for the rat and 70 mg per Kg for the rabbit. The response of both of the species of animals to Evipal intoxication is described. The M. L. D. for the rat is 280 mg per Kg, the toxic anesthetic hypnotic ratios in the rat being 100:36:18. The authors conclude that this compound has a high coefficient of effectiveness.—A. H. MALONEY and R. HERTZ *J Pharmacol*, 54 (1935) 77 (H. B. H.)

Follicular Hormone—Assay of, in Commercial Preparations The assay method employed for a large series of commercial preparations was the following Of a group of 9 castrated mice, 3 were given an amount corresponding to the claimed unit, 3 an amount 20% lower and 3 an amount 20% higher A positive reaction was determined as usual by the vaginal streak The smallest amount giving a positive reaction was then injected into 20 mice, while 20 further mice were given a unit of the standard preparation under the same conditions In the majority of instances, 20 additional mice received either a 20% higher or 20% lower dose subcutaneously in order to substantiate the results An ovarian preparation made from crystalline follicular hormone and containing 10 mouse units per cc and giving a positive reaction in 90% of animals, was used as a standard for the water soluble preparations, and one containing 500 mouse units per cc and giving 95% positive reactions was used for comparison with the oil soluble hormone preparations The results were as follows for number mouse units per cc as claimed and as found and for percentage positive reacting mice, respectively (I) Water soluble preparations Fontanon 100, 100, 78, Hovigal 100, 100 83, Hormofollin 100, 200, 80, Menformon 100, 133, 85, Oestrarin 100, 100, 75, Ovodis Extract 100 100, 73, Ovoglandol 50, 50, 92 5, Ovolut 50, 50, 70, Panhormon 50, 40, 70, Progynon 20, 20, 98, Uden 10, 10, 73, Agomensin —, 10, 85, Ovaralopton —, 0, —, Ovarium-Extract —, 0, —, Rejuven —, 0, —, (II) Oil soluble preparations Perlitan 1000, 1000, 87, Sistomensin —, 1, 70, (III) Solid preparations (tablets, etc.), where unit is per tablet or dragee Novarial 150, 150, 70, Oestrarin 100, 100, 80, Oophoron 50, 50, 92 5, Ovanorm 20, 20, 92 5, Ovoglandol 20, 20, 95, Ovosedicyl 10, 10, 80, Ovotransannon 10, 10, 95, Panhormon 10, 7-8 75, Biovar —, —, Novokap —, —, Ovaraden —, —, Ovaria sicc (Grubler) —, —, —, Ovaria sicc (Merck) —, 3, —, Ovarial tablets —, 16-20, —, Ovarial powder —, 4, —, Ovarigen —, 2, —, Ovarium tablets —, 2, —, Ovarochrom —, 2 —, Ovoglandosan —, 1 5, —, Ovohorma —, 1, —, Vitrisol in Ovaria —, traces, —, Zettolax —, traces, — In the case of the latter preparations the unit value based on 100 Gm dry substance was calculated to be Biovar 4000, Novokap 1500, Ovaraden 800-900, Ovaria sicc (Grubler) 2000, Ovaria sicc (Merck) 4300, Ovarial powder 4000, Ovarigen 2000, Ovarium tablets 4000, Ovoglandosan 1250—M KOCHMANN *Arch Exptl Path Pharmacol* 177 (1935), 526, through *Squibb Abstr Bull*, 8 (1935), A-591

Gonadotropic Hormone—An Improved Method for Determination of the A method of extraction of 40 cc of blood by acid alcohol method is described The material is tested on an immature female rat—U J SALMON and ROBERT T FRANK *Proc Soc Exptl Biol Med*, 32 (1935) 1236 (A E M)

Liver Preparations—Use of Pigeons in the Assay of The results of previous workers are summarized The following method for staining pigeon reticulocytes is recommended A drop of blood is taken up in a graduated micro pipette and blown on to a waxed slide Exactly twice the volume of stain (aqueous solution containing 0.3% brilliant cresyl blue and 1% sodium citrate) is added and mixed with the blood Incubate for 15 minutes at 35° C, then immediately make thin smears on a clean glass slide, spreading with the edge of another slide and dry in the air Allow to stand for 1 hour before counterstaining for 3 minutes with undiluted Jenner's stain The staining solution should be fresh Only "densely reticulated" cells (cells showing a complete or almost complete ring of reticulum around the nucleus) should be counted No correlation could be found between the reticulocyte count and administration of liver extract to pigeons that had been fed on a grain diet The author suggests the use of a mammalian test-animal for reticulocyte tests, because the reticulocyte percentage of the blood of mammals is a definite figure and is easily obtained—M R GURD *Quart J Pharm Pharmacol*, 8 (1935), 39-53 (S W G)

Magnesium Salts—Comparative Studies on the Utilization of Different Little information is available concerning relative utilization of magnesium compounds occurring naturally in food-stuffs as compared with the lactate and citrate and inorganic magnesium compounds The present study was undertaken for the purpose of finding out if there were differences Young white rats were used as experimental animals Calcium and phosphorus balances were carried at the same time Calcium phosphorus and magnesium concentrations were kept fairly constant Formulas for diet are given and all details are reported The different compounds used do not differ materially in absorption or utilization The greatest and the least retentions were obtained with the same magnesium salt Magnesium absorption measured by the sum of the urinary and retained magnesium averaged 32.5% of the intake varying between 29 and 41% "Carswell and Winter have shown that after oral administration of magnesium lactate one may obtain either high

calcium and low magnesium or low calcium and high magnesium retentions " Probably magnesium compounds in linseed meal and alfalfa producing low calcium and high magnesium retention is not due to any difference in behavior Addition of sodium carbonate up to 2% of the diet had no unfavorable effect on utilization of calcium, phosphorus or magnesium —J C FORBES and F P PITTS *J Am Pharm Assoc*, 24 (1935), 450 (Z M C)

Male Fern—Rhizome and Extract of After reviewing the methods of bioassay of male fern, the author describes a method studied at Lund in 1933 The organism used is the tench fish (*Tinca*) of 5-10 cm length A weighed quantity of the drug extract (1 to 20 cg) is triturated with 0.5 Gm sugar and then shaken with a liter of water, saturated with magnesium hydroxide Ten fish are put in each flask with a liter of fluid Concentrations ranging between 0.025-0.001% are used The number of fish killed in 4 to 6 hours is recorded The biological test shows the chemical assay for filicin (as given in the Swedish and the new Danish Pharmacopœias) to be in valid —T AHLM *Farm Revy*, 34 (1935), 309 (C S L)

Mercurial Antiseptics—Action of, on Muscle Oxydase The inhibitory or depressant effect of various mercurials for the muscle enzymes does not run parallel to their antiseptic activity but is rather an index of their toxicity Mercurochrome 1 250 to 1 100, while quite efficient to destroy bacteria, did not inhibit the action of muscle oxydase to any great extent, while solutions of mercuric bichloride (1 10,000 to 1 5,000) were markedly depressant for the enzymes —DAVID I MACHT and HILAH F BRYAN *Proc Soc Exptl Biol Med* 32 (1935), 1244 (A E M)

Morphine, Codeine and Dilaudid—Comparison of Motor Effects of, on Thierry Fistulæ These studies were made upon dogs in which intestinal motivity was determined by the use of balloons inserted into Thierry preparation The authors conclude that morphine, codeine and dilaudid cause prompt spastic effects which are quite similar The minimal dosages in terms of mg per Kg producing a twenty-minute spastic period are dilaudid 0.01, morphine, 0.30, codeine 3.0 Dilaudid was found not to produce the prolonged periods of spasticity characterizing the action of morphine and codeine —ROBERT P WALTON and C FRANK LACEY *J Pharmacol* 54 (1935), 53 (H B H)

Morphine—Effect of, on Human Ureter The effect of morphine on the intact human ureter was studied in 24 patients with presumably normal kidneys, by means of hydrophotographic tracings by Trattner's method Some patients were subjected to radioscopy Subcutaneous doses of 1.8-1.2 gr caused markedly increased tone and larger amplitude of contraction waves in from 2-5 minutes following injection of the drug When increasing doses were given at 1/2 hour intervals, the larger clinical dose of 1/2 gr gave a greater effect than the smaller doses of 1/4 to 1/8 gr The effect lasted at least three hours Doses of 0.01 gr atropine eliminated the contractions of the morphine stimulated ureter with consequent loss of tone Atropine did not act strikingly or consistently when given alone The authors consider that the common idea that morphine quiets the ureter is incorrect Their findings confirm experimental data The literature is reviewed —N F OCKERBLAD, H E CARLSON and J F SIMON *J Urology* 33 (1935), 356, through *Squibb Abstr Bull* 8 (1935), A 661

Nembutal—Effect of, upon Serum Cholesterol of Dogs Nembutal sufficient to produce deep and prolonged narcosis has no influence on the serum cholesterol —E H BLDWELL, F H SHILLITO and K B TURNER *Proc Soc Exptl Biol Med* 32 (1935), 1235 (A E M)

Pharmacological and Toxicological Viewpoints in Cosmetology The action of the following are discussed: water, metallic salts, sulphur, iodine, acids and alkalis, hydrogen peroxide, formaldehyde, tannin, glycerin, alcohol, volatile oils and soaps An extended bibliography is offered —H TRUTWIN *Rieschstoff Ind Kosmetik* 10 (1935), 101-103 (H M B)

Pumpkin Seeds—Anthelmintic Action of The seeds of *Cucurbita pepo* were examined chemically and biologically The test animals were earthworms The fatty oil was extracted in a Soxhlet percolator with petroleum ether A 45% yield of a reddish oil was obtained For the biological test a 5% emulsion of the oil in water and a 10% trituration of the fresh peeled seeds in water were used About 150 cc of each preparation was placed in a beaker and three worms were dropped into each solution The trituration showed anthelmintic action but the emulsion did not The resin extracted from the oil by alcohol was tested as above with negative results Ten per cent aqueous hydroalcoholic and alcoholic extracts were likewise inactive Tests for glycosides, alkaloids and resin were negative The negative results obtained and the prohibition of the use of hot water in making a paste of the seeds suggested the presence of a volatile constituent

ent Fifty grams of the crushed, peeled seeds were steam distilled until 100 cc of distillate were collected This distillate killed worms within 15 minutes The carrier of the anthelmintic action of pumpkin seeds is therefor a volatile substance The experiment was repeated several times with seeds from various sources with similar results except that the activity of the various distillates varied greatly No reason could be assigned for this The following tests applied to the distillate were all negative ferric chloride, Schiff, Millon, Legal, Fehling, Nessler and Deniges reagents, lead acetate and silver nitrate Diazotization and addition of phenol produced no perceptible color The distillate after oxidation with meandrescent strips of copper gave a red color with Schiff's reagent Methyl and ethyl alcohol were not present —A PRISTER *Pharm Ztg* 80 (1935), 394 (G E C)

Pyrethrin I and Pyrethrin II—Relative Toxicity of Pyrethrin I and II were prepared by extraction with kerosene and the mixture purified by dissolving in pentane, extracting with hot methyl alcohol, the alcohol mixed with water and the pyrethrins again extracted with pentane After drying, the solution was cooled to -50° and pyrethrin II precipitated pyrethrin I remained in solution Injected into frogs, (II) produced death in doses of 75 mg per Kg of body weight, (I) in doses of 80 mg per Kg while a mixture of equal parts of (I) and (II) only required a dose of 66 mg per Kg —JEAN RIPERT and OLIVIER GAUDIN *Compt rend*, 200 (1935) 2219 (G W H)

Salyrgan—Intrapleural Injection Intrapleural injections of Salyrgan produce a greater and more lasting diuretic effect than do the intravenous injections —S HORWITZ *Deut Med Wochschr*, 61 (1935), 305 (H R)

Splenic Capsule—Effect of Drugs on the Isolated, of Man and Other Animals The following summary is given 1 A survey was made of the action of various drugs on isolated strips of the capsule of human spleens and the splenic capsules of dogs rabbits, cats rats, guinea pigs and buffaloes 2 Contraction of the splenic capsule was produced by adrenalin, pilocarpine, arecoline or histamine and under certain conditions also by acetylcholine 3 If the tone of the splenic capsule had first been increased by adrenalin, it was inhibited by the addition of atropine pituitary (posterior lobe) extract, sodium nitrite or ergotamine and under certain conditions also by acetylcholine and adenosine 4 The contractor action of acetylcholine was increased by eserine 5 The contractor actions of acetylcholine, arecoline and pilocarpine were abolished by atropine 6 The action of adrenalin was abolished by ergotamine and diminished by cocaine Tracings showing the results obtained are given for each series of actions —K SAAD *Quart J Pharm Pharmacol*, 8 (1935), 31-38 (S W G)

Strychnine and Barbiturates—Elimination of Regardless of the amounts of strychnine administered, the quantities recovered in the urine are small elimination by the kidney being very slow The amounts of strychnine in the organs are also very small The elimination of Gardenal in the urine is also slow, the amounts rejected by the kidney being of some importance —E KERGOUD *Bull soc pharm Bordeaux*, 73 (1935), 53-61 (S W G)

Thymus Extracts—Biological Effects of The outstanding physiological feature of the thymus gland is its growth during youth and involution at puberty A group of American workers (L G Rowntree, J W Clark and A M Hanson) who worked with an extract of calves' thymus found that in rats which were the offspring of thymus treated rats (themselves also treated) until the fifth generation, the appearance of important physiological events such as opening of ears, eruption of teeth, appearance of hair, descent of testes and opening of the vagina, were greatly diminished as compared to the control litters —ANON *Brit Med J*, 1 (1935) 983 (W H H)

Thyroid—Acetonitrile Test for The acetonitrile test for thyroid using mice of both sexes was carried out varying the conditions of observation The susceptibility of mice to acetonitrile poisoning, and the degree of protection afforded by thyroid, are both affected by the temperature at which the mice are kept At 38° C the average lethal dose is about a fifth of that at room temperature, and practically no protection is afforded by thyroid At lower temperatures a protective action can be detected, but the dose/mortality curve for acetonitrile becomes very much flattened, making it difficult to apply the acetonitrile test to a quantitative method of assay —F WOKES *Quart J Pharm Pharmacol* 8 (1935), 54-60 (S W G)

Thyroid—Assay of Various Preparations of Feeding of equal amounts of thyroxin in the form of various thyroid preparations, e g, whole thyroid, iodothyroglobulin, fractionated iodo-

thyreoglobulin, iodothyronin and thyroxin, produced increasing illness in rats. Some of the substances gave a more pronounced calorogenic effect while in the case of the rest, the other general thyroid actions were predominant. This difference appeared to be dependent upon the nature and amount of iodine free and iodine containing substances accompanying the thyroxin. The latter, while inactive or of slight activity in themselves, were capable of influencing the action of thyroxin considerably, e. g., diiodotyrosine had a marked antagonistic effect on thyroid hormone. The thyroxin content of the various preparations examined was determined by splitting the thyroxin component from the accompanying substances by means of alkaline hydrolysis and then determining the amount of thyroxin present either by adjusting the alkaline hydrolysate to pH 5 or extracting it with butyl alcohol and proceeding in a manner previously described.—I ABELIN *Arch expil Path Pharmacol*, 177 (1935), 359, through *Squibb Abstr Bull* 8 (1935), A 630

Thyroxin—Point of Action of Experiments in anesthetized cats (urethane or 5 ethyl 5 phenyl-barbituric acid) before and after decapitation or section of the spinal cord in the cervical or dorsal region indicate that the main point where the action of thyroxin occurs is the midbrain. Increase in metabolism takes place because of irritation of this center.—B V ISSEKUTZ and B V ISSEKUTZ JR *Arch expil Path Pharmacol*, 177 (1935) 442, through *Squibb Abstr Bull* 8 (1935), A-630

Vegetable Extracts and Blood-Sugar Attention is directed to products from vegetable and animal sources, brought out since the discovery of insulin and like it capable of producing hypoglycemia. It was observed, too, that the serum or defibrinated blood of an animal made hypoglycemic by insulin, by the plant extracts, by chemicals, by starvation or by pancreatectomy would lower the sugar in another animal and could even cause death. Apparently there was no limit in the possibility of transmission of decrease in sugar and toxicity from one individual to another. Myrtomel (earlier called myrtillin) had rather marked claims made for it but clinical experience was not encouraging. The present investigation was undertaken to determine the nature of the substance responsible for the power to reduce the amount of sugar in the blood. Experimental work is reported in detail. Rabbits were the test animals. Normal amount of sugar was determined. Determination was also made of the percentage of sugar produced in stated periods of time by specific doses of epinephrine. An extract from the leaves of salal fed to rabbits and subcutaneous injections were without effect. Results with *Vaccinium ovalum* were negative. So some of the work on myrtomel was repeated but results were negative. Then the earlier work of Collip was repeated, using an extract from green onion tops, from lettuce leaves and from cabbage, all with negative results. Attempts to verify Collip's observation that hypoglycemia can be transmitted from one animal to another resulted in failure. The authors conclude that "reputed therapeutic value of plant extracts in the control of blood sugar is erroneous." Collip's work might indicate that the large quantity of liquid injected and the period of starvation could derange metabolism. Other works apparently drew conclusions from too few experiments. The authors believe it entirely reasonable to question the existence of evidence that plants contain a substance which will alter amounts of sugar in the blood.—PAUL S JORGENSEN and E V LYNN *J Am Pharm Assoc*, 24 (1935), 389 (Z M C)

Vitamin A—Various Methods for Determination of A brief review of physical and biological methods (especially the U S P Interim Revision method) for the determination of vitamin A with bibliography.—B RÖNNMARK *Farm Revy* 34 (1935), 369 (C S L)

Vitamin D—Content of, in Salve Bases Containing Cholesterol I Absorption through the Intestinal Mucosa. Anhydrous lanolin contains the provitamin, which on proper irradiation is transformed into vitamin D and then possesses antirachitic properties, yet lacks toxic action, e. g., does not produce calcium deposits. II Absorption through the Skin. The vitamin D produced in these salves by proper radiation is absorbed through the skin and then exerts its antirachitic action without toxic action. Under comparable conditions essentially more vitamin D is absorbed through the intestinal mucosa than through the skin. Either ordinary or irradiated ergosterol apparently causes a thickening of the elastic coat in the rabbit aorta, cholesterol does not exert this action. Irradiated ergosterol is absorbed through the skin.—A ST VON MALLIN, CKRODT-HAUPT *Z Vitaminforsch* 4 (1935), 1, 16, through *Chem Abstracts* 29 (1935) 3463

Vitamin D—Determination of A review and discussion of the U S P Interim Revision (1934) method for the determination of vitamin D.—B RÖNNMARK *Farm Revy* 34 (1935) 233 (C S L)

Vitamin Standards—International International standards for vitamins A, B₁, C and D are now available for issue to laboratories, institutions and research workers in Great Britain and Northern Ireland. The National Institute for Medical Research, London, will continue to supply these standards. The standards for the vitamin B₁ and D remain unchanged and their supply at regular half yearly intervals will be continued as before. The standard for vitamin A has been changed, a pure specimen of β carotene having been adopted in place of the impure preparation hitherto employed. The unit of vitamin A remains unchanged, though it is now defined as the vitamin A activity contained in 0.6 microgram of pure β carotene.—*Pharm J*, 134 (1935), 353

(W B B)

TOXICOLOGY

Acetanilide Poisoning—Clinical and Experimental Study The author reviews the outstanding signs and symptoms as taken from the records of several patients poisoned by proprietary preparations containing acetanilide. Two dogs were given acetanilide in their diet, in varying amounts. It was found that these animals developed some tolerance to the drug. The red cell count tended to be diminished initially but as the intoxication progressed the rate of formation of the red cells became greater than the rate of destruction. The animals showed marked fluctuation in their methemoglobin response, the greatest concentration occurred six to eight hours after the drug had been ingested. There was a complete reversion of the methemoglobin to hemoglobin within forty-eight hours. During the methemoglobinemia the oxygen capacity falls and symptoms of anoxemia may result. Electrocardiographic studies revealed no changes of significance.—*SHELDON PAYNE J Pharmacol*, 53 (1935), 401

(H B H)

Atophan Poisoning A description of a case of fatal liver damage after several weeks' use of Atophan is given. Overdosage and continuous use without intervals were avoided, thus stressing the danger of this drug.—*HUBERT HABES Deut Med Wochschr*, 61 (1935), 173-174

(H R)

Boric Acid Preparations—Toxicity of Skin Disturbances through the Use of Defatting Agents Containing Boric Acid Four cases of skin diseases were observed which were directly attributable to the use of defatting agents containing boric acid. The symptoms were an itchy redness of the chin, neck, head and trunk, thickening of the skin which was covered with very fine scales and vesicles, appearance of the trunk and extremities resembling that in pityriasis rosea, or an erythematous, scaly and very itchy exanthema of the trunk, neck and flexor sides of the extremities. The symptoms disappeared with discontinuation of the use of the preparations.—*ALOIS M MEMMESHEIMER Deut Med Wochschr* 61 (1935), 418

(H R)

Caffeine and Theobromine—Effect of, upon Digitalis Toxicity Employing the cat method of Hatcher and Brody the authors assayed ouabain, strophanthin, digitoxin and three tinctures of digitalis and compared the values so obtained with those upon cats receiving varying amounts of caffeine or theobromine subcutaneously or intravenously. Small doses of caffeine or theobromine did not seem to influence the toxicity of any of these digitaloids. Large doses of caffeine and theobromine (30-50 mg \times Kg body weight) seemed to slightly increase the toxicity of all the preparations studied. The results indicate that in amounts ordinarily employed clinically caffeine and theobromine probably do not influence the toxicity of ouabain, strophanthin or digitalis preparations to any appreciable extent.—*H B HAAG and J D WOODLEY J Pharmacol*, 53 (1935), 465

(H B H)

Castor Beans—Toxicity of A fatality following the eating of 15-20 castor beans is reported. The toxic substance ricin was responsible. This causes necrosis in the blood vessels tissues and cells through agglutination coagulation and precipitation.—*ABDULKADIR-LUFTI Deut Med Wochschr*, 61 (1935), 416

(H R)

Fluorine Toxicosis Apples sprayed with barium silicofluoride showed an average fluorine content of 5.6 p p m before washing. It was impossible satisfactorily to clean fruit originally carrying 0.1 gr or more of fluorine per lb. The human tolerance level for fluorine is so low that it seems a dangerous practice to use the compounds of fluorine for spraying purposes. The ugliness of mottled teeth alone causes untold misery to the afflicted persons.—*M C SMITH Am J Pub Health*, 25 (1935), 701

(A H B)

Skin Poisons—A Chapter on Mexican The following plant products produce skin reactions of various types (1) *Comocledia engleriana* causing abscesses on mucous membranes of the mouth which are difficult to heal and may be introduced in tobacco (2) the magic remedy of

Dr Villegas, Marañon (*Makagoninus*, *Anacardium occidentale*) containing cardol, the irritating principle, (3) nettles and similar products such as Junco or Flor de Latigo (whipping flowers) which is the flowers of *Aporocactus flagelliformis* Lem, (4) Maguey manso (*Agave salmiana* Otto), (5) Barbas de chivo or Chilillo de Cerro (*Clematis dioica* L.) which contains an alkaloid, clematine, which, however, is not a skin poison, (6) introduced from Europe is Rabano rusticano (*Armoracia rusticana* Gaertn.), (7) Herba del Coyote (*Polanisia uniglandulosa* Cappariid.), (8) Pica-Pica del Peru (from Peru) is in the Mexican market as "Ojo de venado" or "Ojo de borrico." Some of these poisons act only on the mucous membranes leaving the epidermis unaffected as (9) Pinoncillo or Aveno purgante, the seeds of *Jatropha curcas* L. var *mexicana* (10) the Euphorbiaceae Yepari huatl (*Croton dioicus* Cav.) or Hierba de Zorillo in a short time covers the mucous membranes of the anus with small red spots and inflamed pustules. Others produce inflamed areas under the skin. (11) the sap of Habilla de San Ignacio or Quauhtlatlatzin (from *Hura crepitans* L.), (12) *Hippomane manizella* L. or Mazanillo, (13) Chupire (Chuprene, Tencuate) an unusually irritating poison from the unripe seeds and secretion of *Euphorbia calyculata* H. B. K., (14) the leaves of Cola de pescado, Cola de iguana or Hierba de alacan (*Plumbago pulchella* Boiss.) called by the Aztecs Tlachichinolli whose irritating sap is used to day for the treatment of wounds caused by poisonous insects, flies, scorpions, etc. (15) the most common of all is the poison sumach. Cuau or Mala mujer (*Rhus radicans* L.) An extract of Yobe (*Grindelia hirsutella*, spec. *Californiana*) is of help in counteracting these poisons if applied immediately.—V. A. REKO *Pharm Post*, 68 (1935) 173-177 (H. M. B.)

Sodium Amytal—Detoxification of Amidopyrine by The toxicity of amidopyrine by production of convulsions can be reduced to $\frac{2}{3}$ when optimal doses of sodium amytal are given.—CHARLES L. ROSE *Proc Soc Exptl Biol Med*, 32 (1935), 1242 (A. E. M.)

Sodium Formaldehyde Sulphoxylate—Use of, in Acute Mercury Poisoning The author demonstrates the protective effect of formaldehyde sulphoxylate against mercury poisoning in rabbits, verifying the results that he had previously obtained upon dogs. The substance has been utilized clinically and found to be of distinct value in mercury poisoning. The author suggests the following procedure in its use in the treatment of clinical bichloride poisoning: 1. Gastric lavage with a 5% solution of sulphoxylate, about 200 cc being left in the stomach. 2. Immediately following this, 10 Gm of the drug dissolved in 100 to 200 cc of distilled water to be slowly injected intravenously, from twenty to thirty minutes being permitted for the injection. 3. In severe cases a repetition of the intravenous injection from four to six hours following the completion of the first injection, from 5 to 10 Gm being injected. 4. If colitis develops later high colonic irrigations with a 1:1000 solution of sulphoxylate.—SANFORD M. ROSENTHAL *J Pharm Med*, 54 (1935), 34 (H. B. H.)

THERAPEUTICS

Calcibronat—Clinical Experience with *Calcibronat*, $(C_{12}H_{21}O_{12})_2 Ca CaBr$, is used in the treatment of nervous exhaustion, hypererethism, hyperthyroidism and epilepsy. Due to the synergism existing between the calcium and bromine it can be given in small doses which are effective, over a long period of time without causing bromism or bromide acne.—K. KEUS *Deut Med Wochschr*, 61 (1935), 799-801 (H. R.)

Carcinoma as an Electrical Phenomenon of Protein Substances The theories of protein formation and their chemistry and those devoted to their connection with tumor and carcinoma formation are fully discussed. It is concluded that a possible remedy against this malady must be capable of regulating the "redox"-potential of glutathione or its heavy metal complex. Such a buffer must be a disulphide as well as an albumin. These regulators have been made by the worker and tried upon certain cases with good results.—O. HUPPER *Pharm Monatsh*, 16 (1935) 92-96 (H. M. B.)

Chloral—Use of, in Infant Therapy Chloral is generally employed in the treatment of convulsions in infants. The modes of administration are reviewed by G. Schreiber (*Bull Medic* (Feb 10, 1934), through *J Practiens* (May 10, 1934)). The dose is generally 10 to 20 cg per year of age. For convulsions the remedy is prescribed separately or together with potassium bromide as follows: Chloral hydrate 0.3 Gm, syrup of orange flowers 30 Gm, distilled water enough to make 100 Gm. Take 1 teaspoonful every half hour (for an infant of 3 years) until sedation. Chloral hydrate 1 Gm, potassium bromide 2 Gm, syrup of codeine 10 Gm, syrup of

orange flowers 10 Gm, distilled water enough to make 100 Gm Six teaspoonfuls every 24 hours Chloral hydrate 0.1 Gm, potassium bromide 0.25 Gm, boiled water 40 Gm For 1 enema At the same time give a water diet and every 3 hours a warm bath (38°) lasting for 6 minutes This is continued until a sound slumber is produced Chloral hydrate 0.2 Gm, cacao butter 2 Gm For 1 suppository Introduce 1 or 2 every 24 hours In the case of tetanus contractions, chloral will give results when most of the common sedatives are without effect —*L'Un Pharm* (Mar 1935), 68, through *J pharm Belg*, 17 (1935), 429 (S W G)

Cod Liver Oil Ointment "Unguentolan"—Investigation with Cod Liver Oil Ointment "Unguentolan" is of therapeutic value in treatment of severe burns, *Ulcus cruris*, decubital tumors, fistulas, deep wounds, etc The action of vitamins A and D seems to cause a marked regeneration of tissue with excellent cicatrization Parenteral use of vitamins A and D is superior to the oral in the treatment of wounds and burns The remaining constituents of cod liver oil seem to enhance the action of the vitamins The ointment is convenient for clinical use and alleviates pain to a great degree —KURT STRAUSS *Deut Med Wochschr*, 61 (1935), 50-52 (H R)

Digilamid—Clinical Studies with Intestinal and Parenteral Administration of Clinical experiments for the last year and a half involving some 100 cardiac patients substantiate the findings of many other investigators regarding the good tolerance, rapid diuretic effect and excellent administration of Digilamid When using the enteral form of administration, it was found that 15 drops of Digilamid 3 times a day *per os* correspond to 3 doses of 0.1 Gm standard digitalis leaves There were some isolated failures due to individual hypersensitivity and idiosyncrasy In the latter case, Digilamid was often given successfully in the form of an enema, the best formula even in severe cases of decompensation, being 25-30 drops twice daily mixed with 3-5 cc of 10% glucose solution and 3-5 drops opium tincture Further potentiation of diuretic action was realized by the addition of 0.3 Gm Theocin The intravenous route which is also very effective, is limited to those cases which cannot tolerate the drug perorally and there is urgent need for rapid absorption of the greatest possible amount of Digilamid Here it is advisable to dilute the Digilamid with 10 cc calcium gluconate or 10-15 cc 10-20% glucose Considerable shortening of the treatment can be affected by combining with diuretics such as Salyrgan, which appear to be more active following the administration of Digilamid Digilamid does not seem to have the cumulative property to as great a degree as the other digitalis preparations Clinical blood pressure and water balance are claimed to be more accurate criteria for ascertaining when Digilamid treatment should be stopped than the appearance of bradycardia and electrocardiographic changes The latter may be independent of Digilamid dosage —E-E BAUKE *Deut Med Wochschr*, 61 (1935), 371-375 (H R)

Digitalis—Effect of, on Pneumonia A study of 1456 cases of lobar pneumonia indicated that digitalis had no apparent effect on the course of the disease, but seemed beneficial in its influence on auricular fibrillation and flutter in favorable cases 34 references —A E COHN and W H LEWIS *Am J Med Sci*, 189 (1935), 457, through *Squibb Abstr Bull*, 8 (1935), A 615

Dye Solutions—Therapeutic Stable solutions suitable for use by injection in combating infectious diseases contain a 3,6 diaminoacridine compound such as 3,6 diamino 10 methyl-acridinium chloride and an excess of a sulphonated dye such as trypan-blue, trypan red or acid fuchsin —LOUIS BENDA (to Winthrop Chemical Co) U S Pat, 1,999,750 (April 30 1935)

(T G W)

Folinerin In cases of cardiac insufficiency with and without disturbances in rhythm and wherein digitalis treatment was indicated, the new glucoside folinerin from *Folia Neri Oleandri*, produced a complete effect on pulse, diuresis, body weight and congestive symptoms, the diuretic action was especially marked The dosage was 15 drops of the solution (= 0.2 mg folinerin = 240 frog doses) three times daily in moderate and severe cases After 8-10 days, further dosage was unnecessary or could be reduced Rectal administration of suppositories containing 0.2 mg of the glucoside were as effective, about 20 were given in the course of 8-14 days The rapidity of the action (in 7 cases within 24-36 hours usually 5-6 days) and the effectiveness of the oral or rectal routes make intravenous injection unnecessary Folinerin exhibited the complete effect of digitalis in its action on disturbances in the production and conduction of cardiac activity No unpleasant side reactions or cumulation symptoms were observed after the usual 8-20 days or chronic treatment The action was not only complete, but prolonged Folinerin is important as a cardiac remedy because it is a chemically uniform pure glucoside independent

of any standardization methods and shows constant activity. It is highly recommended for general practice. The present study involved 80 cases of which only five proved refractory.—R SCHWAB *Klin Wochschr*, 14 (1935), 564, through *Squibb Abstr Bull*, 8 (1935), A 704

Gastro-Sil—Use of, in Nervous Hyperacidity. A neutral insoluble calcium silicate, administered in doses of one teaspoonful three times a day in warm water at meal time for the treatment of nervous hyperacidity.—FELIX OEFELIN *Deut Med Wochschr*, 61 (1935), 597-598 (H R)

Heart Lesions—Therapeutics of Non-Decompensated. The fact that digitals is not specific for all heart lesions is stressed. Citations of the literature and the author's own opinions concerning indications and contra-indications of digitals in various cardiac diseases are presented. Quinine and quinidine are reviewed as to their value in heart therapy. The efficacy of a circulation hormone sugar therapy with admixture of cardiac glucosides and calcium in cardiac lesions is discussed. Treatment of syphilitic heart lesions and affections of blood vessels are also discussed.—P MORAWITZ *Deut Med Wochschr*, 61 (1935), 1-4, 45-48 (H R)

Hypotensive Hormone. Cause of Protein Shock. The hormone, lymphoganglin isolated from the lymph glands induces all the actions of protein shock. Due to this fact it is thought to be the etiological factor in this condition. Where protein therapy is unsuccessful due to an impaired lymphatic system, it is advised that this hormone be used.—G DE NITTO *Deut Med Wochschr*, 61 (1935), 339-341 (H R)

Liver Extracts—Characteristics and Therapeutic Use of, Treatment of Anemias of Bacillary Origin. A review abstracted from the literature.—LUCAS F DEFELICE *Semana med (Buenos Aires)*, 42 (1935), 1086 (A E M)

Lubrokal—Clinical Investigations of. Very effective in treatment of nervous headaches, general nervousness, chorea minor, psychic depressive states, insomnia, nervous types of heart and respiratory disturbances etc. Obtained in tablet form containing 0.6 Gm bromine as ionized potassium bromide and 0.04 Gm sodium ethylphenylbarbituric acid in each tablet.—ANTON SCHUMACHER *Deut Med Wochschr*, 61 (1935), 378-379 (H R)

Lymphatic Leukaemia—Treatment of. The effect of Lugol's iodine solution in chronic lymphatic leukaemia has been investigated. A definite reduction in the white cell count was seen in two out of five cases. The administration of iodine produced no noticeable symptomatic relief. Even in favorable cases the effect of iodine is small compared with that of X ray therapy, the latter remains the best treatment at present available for chronic lymphatic leukaemia. The nature of the effects of iodine seems to suggest that it acts on the leucocytes themselves rather than on the leukaemic process. The bearing of these results and those of previous writers on the aetiology of leukaemia, especially its relation to hyperthyroidism, is discussed.—M C G ISRAELS *Brit Med J*, 1 (1935), 1021 (W H H)

Mandelic Acid—Value of, in Urinary Infections. An attempt to discover a therapeutic agent that might replace the ketogenic diet in the treatment of urinary infections has led to the clinical trial of mandelic acid. Mandelic acid appears to be effective in cases of urinary infection unassociated with urinary obstruction and it is hoped that a more wide-spread trial of the acid may confirm the work previously given.—M L ROSENHEIM *Lancet*, 228 (1935), 1032 (W H H)

Methylene Blue—Treatment of Wound Diphtheria by. E Melchoir (*Zentralbl f Chir* (March 2, 1935), 481) states that diphtheria, as a secondary and non-malignant complication of surgical wounds, became comparatively frequent in certain parts of Germany from 1919 to 1925. It then seemed to disappear, but Melchoir of late has seen it somewhat more often. An indolent wound results either with a characteristically 'greasy' appearance or with recurrent formation of membrane. Intact granulation tissue forms an impassable barrier against diphtheritic as also against tetanus and typhoid toxins and treatment by parenteral antitoxin injections in these non-toxic cases is usually fruitless. The inefficiency of local antiseptic treatment in wound diphtheria has been widely recognized. Melchoir publishes a further recommendation of the treatment which he has found more effective—namely, application of powdered methylene blue. This quickly penetrates granulation tissue and leads within twenty-four hours to blue coloration of the urine, it has been found to be followed within seven to fourteen days by the disappearance of diphtheria bacilla. The application should be pursued for one or two weeks. Melchoir has also found it successful in nasal diphtheria and cutaneous diphtheria.—*Brit Med J* 1 (1935) 1204A (W H H)

Novophyllin—Clinical Experience with Novophyllin (theophyllin phenyl ethyl barbituric acid ethylene diamine) is a cardiac tonic and diuretic. It is not limited to oral use but can be used rectally, intravenously and intramuscularly.—W SOMMER *Deut Med Wochschr*, 61 (1935), 633-635 (H R)

Orthosichol Clinical Investigations of a New Preparation from Koemis Koetjung, the Indian Kidney Tea. Orthosichol, a preparation from the Indian drug Koemis Koetjung, and also found in *Orthostiphon stamineus* Benth, has been proved an effective agent in the treatment of diseases of the biliary apparatus. Besides promoting diuresis, it markedly increases the secretion and expulsion of bile. At the same time, it enhances the secretion and glycogen storage in the hepatic biliary region. An analgesic and anti-inflammatory action is displayed in infectious biliary tract diseases. The average dose of orthosichol is 25 drops 3 times a day *per os*, severe cases require 2-3 cc intravenously each day.—HELMUT RUTENBECK *Deut Med Wochschr*, 61 (1935), 377-378 (H R)

Pernicious Anemia—Liver and Drug Therapy in. Until recently, arsenic has been the chief element used to combat the disease. Many forms of arsenic have been used. It is now generally conceded that if arsenic did produce an improvement it was due to its destructive action on the liver, with the liberation of the specific antianemic principle. The idea of diet as a curative agent is not a new one, but usually the diet prescribed was non nitrogenous and chosen rather for the dyspepsia and for the atrophic condition of the stomach than for any specific effect on the blood. The following conclusions were drawn: (1) There is a definite and stable antianemic principle ready formed and stored in liver. (2) There is, in normal gastric secretion, an intrinsic factor, capable of producing this antianemic principle by interaction with beef and other muscular tissues. (3) This intrinsic factor is not hydrochloric acid or pepsin. (4) There is in beef and other muscular tissues which are not themselves antianemic, an extrinsic factor, capable of reaction with the intrinsic factor of stomach to produce the antianemic principle. (5) The activity of hog stomach is due to the interaction between the mucosal intrinsic factor and the extrinsic factor found in the muscle coat. (6) The antianemic principle is readily synthesized within the body from ordinary foods in normal gastric conditions, but the absence of the intrinsic factor in the gastric mucosa determines the onset of pernicious anemia.—B L STANTON *Australasian J Pharm*, 16 (1935), 165 (T G W)

Pernocton—Value of, in Basal Narcosis. Basal narcosis has been produced in 230 cases with Pernocton (5- β bromallyl-5 sec butyl barbituric acid) with and without the addition of ether. Advantages and disadvantages have been noted.—HELMUTH GREGER *Deut Med Wochschr*, 61 (1935), 170-173 (H R)

Potassium Bismuth Tartrate—Oral Administration of, in Syphilis. J A Kolmer (*Arch Derm Syph* (Jan 1935), 9) draws attention to the value of administering bismuth by mouth in syphilis. It is not suggested that this should replace the more effective intramuscular bismuth medication, but that it is of use in the following instances: (1) as a follow up in between the courses of injections of N A B or bismuth, or when the patient is unavoidably prevented from taking injections for a short period, (2) as a method of starting treatment in chronic syphilis particularly cardiovascular syphilis, and (3) for occasional use by patients who are traveling or who cannot tolerate injections. The preparation recommended is water soluble potassium bismuth tartrate which is of high spirocheticidal value and low toxicity. The dose for adults is 2 to 3 grains in a capsule three times a day.—ANON *Brit Med J*, 1 (1935), 73 (W H H)

Prominalettes—Use of, as Sedative. Tablets containing 0.03 Gm Prominal (5 ethyl-1-methyl 5 phenyl barbituric acid) have been successfully used as a sedative in 60 cases including *Enuresis nocturna*, nervous insomnia, climacteric disturbances, nervousness, hyperthyroidism, etc.—PAUL PLAUT *Deut Med Wochschr*, 61 (1935), 175 (H R)

Prontosil—Use of, in Puerperal Fever. It is recommended that every type of puerperal fever be treated with intravenous injections (20 cc 1-2 times daily) of 0.25% solution of the hydrochloride of 4 (2',4'-diaminophenylazo)-benzenesulfonamide (Prontosil), supplemented by oral treatment with 0.3 Gm tablets. The red crystalline powder which dissolved to an orange-red liquid can also be administered subcutaneously. It was successfully used in 2 cases of streptococcal 2 staphylococcal, several of streptococcal staphylococcal and 13 undiagnosed puerperal fevers.—EUGEN ANSELM *Deut Med Wochschr*, 61 (1935) 264-265 (H R)

Prontosil—Use of, in Streptococcal Infections. Prontosil, 4-(2',4'-diaminophenylazo)-

benzenesulfonamide-HCl, is recommended in 1-2 daily intravenous injections of 10-20 cc of a 0.25% solution or 3 doses of 0.3-0.6 Gm perorally in all severe forms of streptococcal angina and its complications, erysipelas the initial stages of Sepsis lenta, in progressive and severe endocarditis lenta where *Streptococcus viridans* has been identified and in certain forms of infectious polyarthritis. The dye is claimed to be non-toxic and well tolerated. Only rarely were gastric pains and vomiting observed after oral doses. Intravenously there were no unpleasant symptoms. Circulation, respiration, blood pressure, pulse frequency, intestine and urine remained unaffected.—PH KLEE and H RÖMER *Deut Med Wochschr*, 61 (1935), 253-255 (H R)

Pyramidon Therapy—Side Reactions of Explanations and problems of Pyramidon therapy and toxic reactions are presented.—LORZE *Med Klin* (1934), through *Deut Med Wochschr*, 61 (1935), 319 (H R)

Quinidine and Strychnine—Use of, in Treatment of Premature Contractions A case history is given in which, of the various treatments used, quinidine sulphate (gr. iii) and strychnine (gr. 1/60) thrice daily gave the greatest freedom from extrasystoles and from the accompanying symptoms and improved the compensation. Sixteen of 20 other patients with mild cardiac decompensation due to extrasystoles showed a similar favorable response with a combination of quinidine and strychnine. Possibly the chief factor in preventing the more wide spread use of quinidine is the number of warnings, considerably overemphasized, of its dangers.—J BAILEY CARTER and EUGENE F TRAUT *Am J Med Sci*, 189 (1935), 206, through *Squibb Abstract Bull* 8 (1935), A 551

Quinine—Therapy of Respiratory Diseases by Quinine in the form of Solvochin (25% aqueous quinine solution in slightly alkaline medium) and Transpulmin (camphor oil solution of quinine) is very effective when injected intragluteally in chronic diseases of the respiratory organ.—B THOMS *Munch med Wochschr*, 82 (1935), 420, through *Squibb Abstr Bull*, 8 (1935), A-597

"Sea Sickness Remedy Bayer" A discussion of its use in sea sickness.—CARL LUDWIG to SCHMIDT *Deut Med Wochschr*, 61 (1935), 798-799 (H R)

Silver Manganite Preparations—Use of, in Dermatology Silver manganite in admixture with an ointment base made from vaseline and ground nut oil and buffered to pH 5.4, has been found to have a healing effect on leg ulcers, wounds of all types, dyshidrotic eczema and impetigo contagiosa. A preparation containing silver manganite, benzoin tincture and ether gave a good bactericidal effect in cases of impetigo contagiosa, folliculitides, moist and impetiginous eczema and all forms of intertriginous eczema and produced rapid drying of the affected parts so that growth of bacteria and fungi was stopped.—A PILLOKAT *Munch med Wochschr* 82 (1935), 540, through *Squibb Abstract Bull*, 8 (1935), A-554

Specialties and Products of Research in 1934 A review of the progress in hypnotics, therapy of snake bite by serums, treatment of cancer, hormones, vitamins, enzymes, new specialties, oligodynamics of silver, discovery of new elements, and heavy water, new apparatus and experimental methods.—K SCHULZE *Apoth Ztg* 50 (1935), 207-211, 227-231 (H M B)

Strophanthin—Treatment of Angina Pectoris by Strophanthin was used with good results in 66 cases of angina pectoris in doses of 0.2-0.4 mg given daily for three days followed by one day's interval. Several cases required larger doses.—H ZIMMERMAN *Munch med Wochschr*, 82 (1935), 286, through *Squibb Abstract Bull* 8 (1935), A-599

Sulfarsenol in Erysipelas P. Barre (These de Paris, 1935, No 57) reports thirty-four cases in patients aged from 18 months to 78 years, fifteen of which were mild, twelve severe and seven very severe. Arsenical treatment may be administered by subcutaneous, intramuscular or intravenous routes. The dosage depends on the age of the patient, the state of his liver, kidneys and heart, and the severity of the attack. Usually the dose for adults is 12 cg, which may be increased by 6 cg daily, while that for the child is 0.5 cg per kilo of body weight. The average number of injections required is about two. As a rule they should be given every two days except in severe cases where more energetic treatment is necessary.—*Brit Med J*, 1 (1935), 1060B (W H H)

Syphilis and Malaria—Investigations in Combating A review.—B HEINZ *Pharm Monatsh*, 16 (1935), 41-45 (H M B)

Urea—Value of, as a Diuretic "Ituran" (effervescent urea tablets) intravenous injections of a 40% aqueous urea solution and intravenous intraperitoneal or intrapleural injections of

Salyrgan with urea have a very good diuretic action in heart muscle diseases and are without secondary manifestations—K WERSE M m W, Nr 48, through *Deut Med Wochschr*, 61 (1935), 35 (H R)

Vitamin D—Absorption of, through the Skin The author has shown that rickets may be cured in rats after 8 days by rubbing irradiated ergosterol into the skin A solution of the vitamin was made in olive oil A dose of 5 $\frac{1}{2}$ international vitamin D units was not satisfactory however a dose of 10 units gave results The result was determined by the "line test"—M E FODOR *Zeitschr f Vitaminforschung* (1934), 241, through *Pharm Weekblad*, 72 (1935), 697 (E H W)

NEW REMEDIES

SPECIALTIES

Abüsan Capsules (Busano Laboratories), an analgesic in the treatment of migraine and rheumatism, contains the diethylbarbiturate of dimethylaminophenyldimethylpyrazolon with caffeine citrate in equimolecular amounts besides saponin—*Pharm Monatsh*, 16 (1935), 50 (H M B)

Aderol (Kynazon-Werk, Frankfurt) is an external alcoholic preparation containing *d*-bornyl acetate (1%), an isothiocyanic ester (0.5%), camphor (5%) and ethereal oil (17%) used in the treatment of whooping cough, bronchitis and pneumonias of infants and older children—*Drug and Cosmetic Ind*, 36 (1935), 775 (H M B)

Alloton (Riedel-de Haen, Berlin) is a chemical combination of garlic oil (12%) and dioxycyclic acid Each coated pill contains the active constituent of 1 Gm fresh garlic It is used in digestive disorders, worms, climacteric changes and arteriosclerosis—*Drug and Cosmetic Ind*, 36 (1935), 775 (H M B)

Anox (Schering-Kahlbaum A G) is a grain weevil preparation which is used as a spray (1:10) to purify and disinfect granaries—*Pharm Monatsh*, 16 (1935), 97 (H M B)

Antigihda (Breit and Co, Hamburg), a liniment for rheumatism, is a yellow solution of hexamethylenetetramine and salicylic acid perfumed with oil of mirbane yielding a residue upon evaporation of about 20%—*Apoth Ztg*, 50 (1935), 253 (H M B)

Apicosan N (Dr A Wolf, Bielefeld) is a special form of the bee poison preparation Apicosan and is used to combat neuritis, etc—*Pharm Monatsh*, 16 (1935), 8 (H M B)

Arojocol (Schwanen-Apotheke, Mainz) is a constructive tonic for children and adults containing cod liver oil, chalk, sodium ammonium phosphate with the addition of Recresal—*Pharm Monatsh*, 16 (1935), 8 (H M B)

Askaridol Dragees (Bayer) consists of the active constituents of oil of chenopodium (50%) in 4-beta diethyl amino ethoxyolyl anilid benzoate in packages of 20 dragees equivalent to 0.015 Gm ascaridol—*Pharm Post*, 68 (1935), 210 (H M B)

Baldronit (Otto Reichel, Fabrik pharm und biol Erzeugnisse, Berlin-Neukölln) is an alcoholic preparation of the root of *Valeriana montana* and of adonis herb to which is added ethylallyl-malonylurea amidopyrine (12.5%) It is used as a sedative and nerve for heart neuroses, epilepsy insomnia and hypertonia—*Pharm Zentralh*, 76 (1935), 291 (E V S)

Baldronit cum Nitro (Otto Reichel) contains 0.5 Gm of a 1% nitroglycerin per 100 Gm of Baldronit It is indicated for coronary sclerosis, angina pectoris and stenocardia—*Pharm Zentralh*, 76 (1935), 291 (E V S)

Bevitone (Merck and Co) is a highly concentrated preparation of Vitamin B from wheat germ and rice bran Each fluidounce represents approximately 2000 Chase-Sherman units—*Drug and Cosmetic Ind*, 36 (1935), 773 (H M B)

Bickmorin (Bickmorin, Gall Kure & Co, Old Town, Me) for sores and injuries of all sorts of horses and cattle consists of 33% vaseline 31.5% saponifiable fats (hog fat?), 1.5% water, 17.5% sulphur, 2.5% indigo, 6% boric acid and 8% alum—*Pharm Monatsh*, 16 (1935), 97 (H M B)

Bisteril Bacilli (Fabrik Dr Wander Ges m b H, Vienna), in packages of 10, consists of Pyraligin (ortho oxyquinoline sulphonylsalicylate), hexamethylenetetramine hydrochloride, sodium bicarbonate—*Pharm Post*, 68 (1935), 213 (H M B)

Blumal (Lab de Pharm Med, Paris) is a solution of hexamethylenediamine iodomethylate

dimethylene diamine salicylate and papaverine hydrochloride in ampuls for rheumatic affections — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Brocanal (Curta & Co., G m b H Berlin) is marketed in tablets containing 0.025 Gm phenylethylbarbituric acid, 0.4 Gm bromcalcium diethanolamine (≈ 0.15 Gm bromine and 0.037 Gm calcium) and 0.015 Gm caffeine and is indicated in epilepsies, mental disturbances depression and climacteric disorders — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Calmural is an ointment containing brominated uranium oxide (9% uranium, 7% bromine) to relieve itching — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Chinoform Powder (Chinosolfabrik A G, Hamburg) consists of potassium ortho oxyquinoline bisulphate (10%) with starch and talc and administered in doses of 25 and 100 Gm — *Pharm. Post*, 68 (1935), 210 (H M B)

Chinoral Dragees (Chinosolfabrik A G, Hamburg) contains 0.10 Gm ortho oxyquinoline with a binding agent — *Pharm. Post*, 68 (1935), 210 (H M B)

Cibalgin Tablets (Chem. Industries, Basel) consists of 0.22 Gm dimethylamino phenyl dimethyl pyrazolon and 0.03 Gm diallyl-barbituric acid — *Pharm. Monatsh.*, 16 (1935), 52 (H M B)

Citrofinal (Chem.-pharm. A G Bad Homburg) is the new name for the sodium chloride free diet- and table salt Citrovin — *Pharm. Zentralh.*, 76 (1935), 292 (E V S)

Cluexin (Lowen-Apotheke, Dresden) for insect bites is a yellow salve in tubes consisting of suprenen, ethyl para amido benzoic acid, menthol and volatile oil — *Pharm. Monatsh.*, 16 (1935), 97 (H M B)

Collumol (Dr. Blajet) is a colloidal peptic aluminum hydroxide employed in stomach affections, in hyperacidity and in abnormal fermentation — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Cophenin Tablets (Pharm. Laboratorium, Gierwitz O-S) contain in each tablet caffeine (0.08 Gm), phenacetin (0.22 Gm) cinchona bark (0.05 Gm), and a series of effective homeopathic doses of antipyretics. It is used as an analgesic, antineuralgic and antipyretic — *Pharm. Zentralh.*, 76 (1935), 338 (E V S)

Corcumen (Temmler Works, Berlin) is distributed as capsules containing 0.1 Gm curcumin-sodium and 0.1 Gm calcium chlorate and ampuls containing 5.5 cc of a 5% solution and are employed in liver and gall bladder diseases — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Cortidyn (Chemische Fabrik Promonta, Hamburg 26) is a standardized extract of the suprarenal cortex. The activity and uniformity of the preparation are controlled by biological tests on mice. It is indicated in Addison's disease, muscle dystrophy, hypogonitism, and other disturbances of the internal secretions. It is used intramuscularly or subcutaneously in daily doses of from 0.5 to 2 cc and is marketed in packages containing 3 and 10 ampuls of 1 cc each — *Pharm. Ztg.*, 80 (1935), 431 (G E C)

Crmol Salve (Chem. Fabrik Gebeka, Dresden), a salve for burns, consists of boric and salicylic acids, of each 0.2 Gm, balsam peru 0.4 Gm, liquid petrolatum 4.2 Gm, yellow wax 5.5 Gm, Venetian turpentine 17 Gm, egg yolk 2 Gm, Xeroform 0.2 Gm and anthrasol 0.3 Gm — *Pharm. Monatsh.*, 16 (1935), 97 (H M B)

Danamine ("Syntetic," Grindstedvaerket, Denmark) identical to Coramine is 3 pyridine carbonic acid and is employed to replace by injection of the 25% solution as a cardiac tonic and in carbon monoxide poisoning — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Danarsine is the calcium salt of allylarsenous acid $C_3H_5AsO_2 \cdot Ca \cdot H_2O$ and has the same composition as Arsyleen — *Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Dispers (Dispert, Ltd., The Hague) are preparations prepared by the dispers method of Krause whereby the liquid extract from plant parts is finely subdivided and sprayed over a surface being dried in the process. The following dispers are prepared: *Aconite Dispert* is made up into tablets equivalent to 0.05 or 0.2 mg per tablet and is employed in neuralgia and migraine; *Aluminum Acetate-Dispert* is powdered aluminum acetate; *Belladonna-Dispert* is belladonna extract free from inert substances and containing only the active constituents of belladonna. It is sold as the powder tablets, suppositories and solution. The powder is standardized to an atropine content of 1.5% (biologically), each tablet contains 0.25 mg atropine and each suppository 0.3 mg. *Colchicum-Dispert* is an extract from colchicum seeds standardized as to colchicine content.

and is sold in capsules for rheumatism *Digitalis Dispert* is a cold water extract of digitalis leaf biologically assayed and sold as a powder, tablets, solution and suppositories *Frangula Dispert* is an extract from frangula in tablet form containing in each tablet 25 mg emodin *Pancreas Dispert* is made from pancreas and is also available as an ointment and a plaster used as an aid to digestion The tablets have a lipase value of 0.25 and the powder a value of 0.35 *Secale-Dispert* is an extract of ergot as suppositories standardized to contain in each 1 mg of alkaloids *Thyroid-Dispert* consists of the dry powder of standardized thyroid gland *Valerian-Dispert* from the root of valerian is physiologically standardized on mice and is sold as capsules—*Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Dolorfug-Balsam (Dr W. Dernbach, Apotheker, Bad Salzschlief) is a yellowish ointment containing camphor, methyl salicylate, chloroform and menthol It is used for rheumatism, ischias and lumbago—*Pharm. Zentralh.*, 76 (1935), 353 (E V S)

Dolorfug Capsules (Dernbach) a nerve pain, migraine and neuralgia remedy, contain dimethylaminopyrazolon, phenacetin, phenazone, magnesium oxide and caffeine—*Pharm. Zentralh.*, 76 (1935), 353 (E V S)

Doryl Solution (Merck) in packages of 3 and 10 ampuls contains in each ampul 0.0025 Gm doryl (addition of trimethylamine to carbaminic acid-beta chlorethyl ester)—*Pharm. Post*, 68 (1935), 213 (H M B)

Dossalax (Apogepha, Fabrik chem.-pharm. Präparate Dr. Starke & Max Biering G. m. b. H., Dresden), a pill for chronic constipation, contains aloe, extract rhubarb comp., and *Ipomæa turpethum* resin—*Pharm. Zentralh.*, 76 (1935), 338 (E V S)

Drei-Nerv-Würfel (Dr. H. Much A. G. Chem. Pharm. Fabrik, Berlin Pankow) a biological nerve builder in tablet form (3.1 Gm) consists chiefly of lecithin, albumin, sugar, grain embryo meal, organic iron and calcium salts—*Apoth. Ztg.*, 50 (1935), 253 (H M B)

Ergostabil (Oest. Heilmittelstelle G. m. b. H.), in ampuls, contains stabilized extract of ergot and 0.5% benzoic acid—*Pharm. Post*, 68 (1935), 212 (H M B)

Eunarcon (J. D. Riedel-E. de Haen A. G., Berlin) is a 10% stabilized aqueous solution of the sodium salt of isopropyl beta bromallyl N-methylmalonyl urca suitable for intravenous injection used as a narcotic in simple surgeries and in gynecology similar to ethyl chloride or as a full narcotic in short operations—*Drug and Cosmetic Ind.*, 36 (1935), 775 (H M B)

Europian Tablets (F. J. Kwizda, Korneuburg) is marketed in packages of 10 and 20 tablets Each tablet consists of 0.26 Gm phenyl dimethyl aminopyrazolon, 0.0112 Gm diethylbarbituric acid, phenylethyl barbituric acid and magnesium peroxide—*Pharm. Post*, 68 (1935), 213 (H M B)

Ezoidon Pine Needle Tablets (H. Edelmann, Berlin) consists of sodium chloride colored with fluorescein and about 1% volatile oil—*Pharm. Monatsh.*, 16 (1935), 9 (H M B)

Ezoidon-Sulphur Bath (H. Edelmann, Berlin) is used for the treatment of skin disorders, furunculosis, itches, eruptions, etc., and consists of soda 82 Gm, pine oil about 3 Gm The sulphur is in the precipitated form—*Pharm. Monatsh.*, 16 (1935), 9 (H M B)

Floraform (Oemata, Chem. Works, Berlin) a deodorant and disinfectant, is a soap solution of formaldehyde (0.05–1%)—*Pharm. Monatsh.*, 16 (1935), 98 (H M B)

Floraform-Cream (Oemata Chem. Works G. m. b. H., Berlin) is a formaldehyde skin cream used to combat excessive perspiration and is a deodorant—*Pharm. Monatsh.*, 16 (1935), 98 (H M B)

Gallacetan Dragees (S. Neumeier, Frankfurt) contains 0.25 Gm dried and powdered black radish, 0.05 Gm sodium glycocholate and 0.05 Gm menthol and is used for liver and gall bladder disorders—*Pharm. Monatsh.*, 16 (1935), 98 (H M B)

Germucid Cachets and Tablets consist of 0.50 Gm of Germucid which is dimethylamino dimethyl oxyquinizin and 33% oxyquinoline sulphonic acid—*Pharm. Post*, 68 (1935), 213 (H M B)

Glykhepar (Nordmarke Werke, Hamburg) used for primary muscle atrophy, myasthenia gravis, pseudoparalytica myelosis, infantile paralysis, etc., is Hepatrat with 20% glycerol in liquid and granular form Dose Liquid—1 tablespoonful 3 times a day, granules—2 heaping teaspoonfuls three times a day—*Pharm. Monatsh.*, 16 (1935), 98 (H M B)

Hucomin Tablets (Hummin Chemie G. m. b. H., Munich-Pasing) used to combat rheumatism, gout, etc., consist of almost crystallizable huminic acid compounds coupled with hexa-

methylenetetramine, methylamine, carbamide They are water soluble and neutral in reaction For the estimation of the pharmacodynamic effect the crystalloidal colloidal character of the humic acid compounds is important, their specific bactericidal properties as well as their reducing and amidate action depends on the splitting up of the nucleic acids They are resorbable and reduce purinamidases and xanthine oxidases as well as uric acid itself with the formation of water soluble complex compounds—*Pharm Monatsh*, 16 (1935), 99 (H M B)

Humaven (Pharmazeutische Handelsgesellschaft m b H, Dusseldorf), a nerve sedative, is prepared from the raw sap of freshly germinated oats, the chlorophyll of spinach and fluid extracts of hops, valerian and Piscidia bark—*Pharm Zentralh*, 76 (1935), 105 (E V S)

Idracafin (Chem Fabrik J D Riedel A-G, Berlin) is a tablet containing 0.5 Gm of Idragin (acetylsalicylic acid Riedel) and 0.05 Gm of caffeine It is used for headache, migraine, tooth ache, rheumatism, ischias, grippe, etc—*Pharm Zentralh*, 76 (1935), 292 (E V S)

Igeneu (Chem Pharm Laboratorium Eduard Lyss, Dresden) is a solution of phenylidimethylisopyrazolon in water treated by silver catalysis with addition of desirable anesthetics It is injected under the skin for neuralgia, neuritis, etc—*Pharm Monatsh*, 16 (1935), 99 (H M B)

Inolène (Lacombe, Paris) is a coal-tar antiseptic containing essence of anise seed 2 Gm, essence of star anise 1 Gm, saccharin 0.2 Gm, tincture of quillaja impregnated with coal tar enough to make 100 Gm—*Bull Ch Synd Pharm Seine* (Feb 1935), through *J pharm Belg*, 17 (1935), 404 (S W G)

Iodéopurine (E Viel et Cie 37, Avenue de l'Opéra, Paris) is marketed in the form of tablets, each containing 0.05 Gm of acetyl-iodo salicylic acid, and as an ointment containing 1 Gm of acetyl-iodo-salicylic acid for each 24 Gm of excipient The tablets are recommended in the following doses: 2 tablets 3 times a day for acute rheumatism and sciatica, 3 to 6 tablets (in 3 or 6 doses) every 24 hours for chronic rheumatism and other infections, 1 tablet with a hot drink at night for preventive treatment for grippe (S W G)

Iodopeptone Cody (Gourdal, to Brive—Corrèze) is a solution of citrated iodopeptone containing iodinated peptone (10%) 50 Gm, sodium citrate 20 Gm, distilled water enough to make 100 cc—*Bull Ch Synd Pharm Seine* (Feb 1935), through *J pharm Belg*, 17 (1935), 404 (S W G)

Katadyn-Silver (Schering-Kahlbaum A-G, Berlin) is a catalytic oligodynamic silver preparation containing 10% of silver and prepared from a 99.99% silver refined with a special surface structure from a fine capillary ceramic powder It is used locally to sterilize infections of the mucous membranes and to disinfect wounds, also by oral administration for various infectious diseases such as duodenal ulcers, dysenteries, diarrheas, etc—*Pharm Zentralh*, 76 (1935), 105 (E V S)

Lygal (Dr G Henning Chem and Pharm Fabrik, Berlin-Tempelhof) is a gout remedy containing 50% calcium phenylquinoline carbonate, 29% dimethyl aminophenazon and 21% caffeine sodio salicylate It is marketed as dragees containing 0.3 Gm, as tablets of 0.75 Gm and as a 30% solution in ampuls The latter two contain the soluble sodium compound instead of the calcium salt—*Pharm Monatsh*, 16 (1935), 54 (H M B)

Métricure (Antoine, Paris) is a vaginal antiseptic containing trioxymethylene 0.1 Gm, essence of lavender 0.1 Gm, essence of geranium 0.1 Gm, tannin 2 Gm, sodium tetraborate 40 Gm and sodium bicarbonate 57.7 Gm One teaspoonful should be dissolved in enough water to make 2 liters—*Bull Ch Synd Pharm Seine* (Feb 1935), through *J pharm Belg*, 17 (1935), 404 (S W G)

Mingol-Extra (H von Gumborn A-G Emmerich a Rh) a cough, croup and catarrh tablet, is prepared from oils of peppermint, anise and fennel ammonium carbonate, formaldehyde glycyrrhiza, sucrose and potato starch—*Pharm Zentralh*, 76 (1935), 338 (E V S)

Mucitekt Tablets (Nordmark-Werke G m b H, Hamburg 21) contain a mixture of mucin plant proteins and the acid binding protein constituents of blood The proteins have a high acid combining power without exciting the gastric juices The preparation has the property of coating the stomach walls to prevent the injurious actions due to food friction and gastric juices The tablets are taken for hyperacidity, ventricular and duodenal ulcers, and gastritis—*Pharm Zentralh*, 76 (1935), 338 (E V S)

Myrrhatan (Labora-Verlag Berlin), a preparation for tooth and mouth care against para

denitis, gum bleeding, etc., is prepared from tinctures of myrrh, rhatany and nutgall, oils of peppermint, salvia and eucalyptus and other ethereal oils of suitable flavor—*Pharm Zentralh*, 76 (1935), 338 (E V S)

Nemural (Bayer) is marketed in packages of 10 tablets each containing 0.018 Gm arecoline 4-ox-3 acetyl amino phenylarsenate—*Pharm Post*, 68 (1935), 210 (H M B)

Neogel Acidulans (Apoth. A. Kremel, Vienna) is sold in packages of 6 small pills and consists of sulphosalicylic, acetic and lactic acids, gelatin, cocoa butter and perfume—*Pharm Post*, 68 (1935), 210 (H M B)

Neogel Antifluoric (Apoth. A. Kremel, Vienna) is marketed in packages of six pills consisting of sodium acetylarsenylate, strontium formate, sugar, dextrin, colloidal copper and Neogel pill mass—*Pharm Post*, 68 (1935), 210 (H M B)

Neogel Antigonorrhoeic (Apoth. A. Kremel, Vienna), in packages of 6 pills, contains silver proteinate, Celasol and pill mass—*Pharm Post*, 68 (1935), 211 (H M B)

Neogel Resorbens (Apoth. A. Kremel, Vienna), in packages of 6 pills, consists of Celasol, iodine, potassium iodide, chloral hydrate and pill mass—*Pharm Post*, 68 (1935), 211 (H M B)

Neurobrom (Bombelon-Werk, Apotheker H. Woelke, Hamburg 20) are bouillon cubes containing in each 11 Gm of sodium bromide, some sodium chloride, meat and plant extractives, condiments and some fat. One cube dissolved in a cup of hot water produces a suitable bouillon for epileptics, neurasthenics or neurotics—*Pharm Zentralh*, 76 (1935), 338 (E V S)

Optolax Tablets (Universitäts Apotheke E. Weber vorm Dr. Chr. Brunnengraber, Rosstock 1, Meckl.) is a cathartic used to prevent increase in weight and for gall troubles. The active ingredients are ext. aloë, ext. cascara, leptandrin and *Ipomœa turpethum* root—*Pharm Zentralh*, 76 (1935), 338 (E V S)

Pandigal is a heart remedy containing the glucoside lanadigin, (0.4 mg) as drops and tablets, ampuls and suppositories are also made containing 0.2 mg—*Pharm Post*, 16 (1935), 74 (H M B)

Penetal (Vial and Uhlmann, Frankfurt) is cyclopentenyl ethyl barbituric acid as colorless prismatic crystals, melting at 163° C., difficultly soluble in cold water while its salts are easily soluble. In doses of 0.1–0.3 Gm (1–3 tablets) it is reputed to be a hypnotic without side reactions—*Pharm Monatsh*, 16 (1935), 74 (H M B)

Poly-propeptan Dragees (Chemosau-Union, Vienna), in packages of 25, contain the peptones from apple, egg, pea, veal, potato, corn meal, milk, rice, beef, spinach, pork and wheat bran—*Pharm Post*, 68 (1935), 213 (H M B)

Postalan-Hæmorrhoidal-Suppositories (Fürstl. Fürstenberg Hofapotheke R. Baur in Donaueschingen) contain ethyl *p*-aminobenzoate, resorcin, bismuth oxydodogallate, zinc oxydate, balsam of peru and cocoa butter—*Pharm Zentralh*, 76 (1935), 338 (E V S)

Pyradial Tablets (Wiedenmann, Basel) contain 0.0336 Gm diallyl-barbituric acid and 0.2129 Gm dimethyl amido antipyrine with corn-starch—*Pharm Monatsh*, 16 (1935), 75 (H M B)

Quinine Ethylphenylbarbiturate Compound (Palatin Apotheke Debreczin) is a new form of hypnotic sedative—*Pharm Monatsh*, 16 (1935), 8 (H M B)

Reichel-Hustentee (Otto Reichel, Berlin-Neukölln) is a cough remedy containing Ledum, althaea, *Tussilago farfara*, salvia, fennel, mint, galeopsis, glycyrrhiza, pimpinella, arnica, eucalyptus, grindeha and thyme. It is used for bronchial catarrh, asthma, grippe, hoarseness and whooping cough—*Pharm Zentralh*, 76 (1935), 306 (E V S)

Reichel-Hustentropfen (Otto Reichel) is a liquid cough drop remedy prepared from a distillate of pimpinella, anise, arnica, salvia, eucalyptus, mint and glycyrrhiza, to which is added camphor (0.1%) benzoic acid (0.4%) and ephedrine (1%)—*Pharm Zentralh*, 76 (1935), 307 (E V S)

Rheumavertan (Ernst Schumann Fabrik chem. Präparate, Berlin-Neukölln), an anti-rheumatic, is a solution of a salicylic acid ester, a small percentage of ammonium phenylquinoline carbonate, camphor, menthol and an ethereal distillate of the pinene and terpene series in sulphurated oleic acid esters of plant oils—*Pharm Zentralh*, 76 (1935), 227 (E V S)

Rynarzol (Chem. Laboratorium Berlin-Norden G. m. b. H. Berlin) a nerve, anemia and

weakness remedy, contains calcium glycerophosphate, hemoglobin, vanillin, cocoa, sucrose and flour — *Pharm Zentralh*, 76 (1935), 338 (E V S)

Salzchlirfer Reducing Pills (Dr W Dernbach, Apotheker, Bad Salzchlirf), a cathartic and fat reducing pill, contains ext rhubarb, ext cinchona, ext aloe, ext cascara sodium taurocholate *Ipomoea tupa* resin and Carlsbad Salts — *Pharm Zentralh*, 76 (1935), 338 (E V S)

Sanovin (Homoopathische Centralapotheke, Prof Dr Mauch, Goppingen) is a homeopathic preparation containing fennel, plantago, drosera *Castanea vesca*, anise, thyme, cratagus stramonium, bryonia, ipecac, potassium sulphoguaiacolate and antimony arsenate. It is used for coughs and bronchial catarrh — *Pharm Zentralh*, 76 (1935), 339 (E V S)

Schachtox (F Schacht G m b H, Braunschweig), which is marketed in two strengths, is a concentrated pyrethrum preparation. The first strength diluted 100–200 times is used for plant lice, while the second is used as a house yard and stable spray for all vermin — *Pharm Zentralh*, 76 (1935) 339 (E V S)

Scillergon Tablets (F J Kwizda, Korneuburg), in packages of 12, consist of the standardized active constituents of squill with pimpinella root — *Pharm Post* 68 (1935), 213 (H M B)

Scilloral (Asta A -G, Chem Fabrik, Brackwede i W) is a patented heart remedy prepared from squill and is marketed as cachets, suppositories and in liquid form — *Pharm Zentralh*, 76 (1935), 307 (E V S)

Sedocalcum occurs in the trade in the following combinations. Iodo sedocalcum as tablets of 0.25 Gm sedocalcum and 0.02 Gm potassium iodide, Theobromine sedocalcum 0.025 Gm sedocalcum and 0.2 Gm theobromine, Iodo sedocalcum-theobromine 0.25 Gm sedocalcum, 0.2 Gm theobromine and 0.1 Gm potassium iodide. These preparations are used for hypotonicity, arteriosclerosis and asthma — *Pharm Monatsh*, 16 (1935), 76 (H M B)

Sensibamine (Chem Fabrik Dr Georg Henning, Berlin-Tempelhof) is a new ergot alkaloid. The increased uterus action due to the alkaloid occurs in 1–2 minutes after intravenous injection or in 10 minutes after subcutaneous injection. It is taken after childbirth to promote the return to normal of the uterus — *Pharm Zentralh*, 76 (1935), 227 (E V S)

Silikat-Hautsalbe (Chem Fabrik Hygiea G m b H, Dresden) an ointment of lanolin and silicic acid, is used for frost-bite, skin eruptions, pimples, red nose and face — *Pharm Zentralh* 76 (1935), 227 (E V S)

Silikat-Milchpuder (Chem Fabrik Hygiea G m b H, Dresden), a dusting powder containing silicic acid in an easily absorbable form, is indicated for wind burn, skin itch, wet eczema and inflammation — *Pharm Zentralh*, 76 (1935), 227 (E V S)

Solvarsin (I G Farben A G) contains 22.4% aqueous solution of 4-oxy 3 acetyl amino phenylarsenic acid amino ethanol in packages of five 2-, 3- and 5 cc ampuls — *Pharm Post*, 68 (1935), 212 (H M B)

Solvochin-Calcium-Ampullen (Chem -pharm A -G, Bad Homburg) contains in each 5 cc ampul 250 mg of quinine corresponding to 1 cc of Solvochin and 72 mg of calcium as calcium glutamate which is dissolved by means of phenyldimethylpyrazolon. The pH of the liquid is 7.2. It is indicated for croup, pneumococci pneumonia, bronchial pneumonia, postoperative pneumonia and other conditions due to pneumococci — *Pharm Zentralh*, 76 (1935) 307 (E V S)

Stabal (Papatin Apothecary of Aba Sztankay v. Germany, Debreczin) is compound quinine ethylphenylbarbiturate and contains ethylbarbituric acid 41.687% quinine 56.376% strychnine 1.936% in chemical combination. It is used as a hypnotic and sedative in doses of 0.05–0.15 Gm for epilepsy for children 0.01–0.02 Gm three times a day, for adults in treatment of the same disorder 0.05 Gm three times a day with a maximum dose 0.2 Gm. For severe insomnia 0.05 Gm are given in morning and at noonday (or 1 pastille) and at evening if necessary 0.10–0.15 Gm (2–3 pastilles). It is a bitter, insoluble white powder easily soluble in alcohol, in p 181–182° C — *Pharm Monatsh* 16 (1935) 12 (H M B)

Stovarsol Sodium (Société Parisienne d'Expansion Chimique Spezia, Paris) is the sodium salt of oxy acetyl amino phenylarsinic acid in ampuls containing 0.50–1.0 Gm — *Pharm Post*, 68 (1935), 210 (H M B)

Styptoplast (Firma Lohmann A -G) (formerly Luscher & Bömper A -G) is the new name for Clauden-Wundverband — *Pharm Zentralh*, 76 (1935), 339 (E V S)

Toxursan (Chem Fabrik Dr Ch Thaler, Wien) is a lithium containing condensate of terpenes and unsaturated fatty acids. It is used as a local treatment for rheumatic and gouty maladies—*Pharm Zentralh*, 76 (1935), 227 (E V S)

Treupel Suppositories (Chem pharm A-G, Bad Homburg) contain in each suppository a 1-Gm Treupel tablet, 0.5 Gm of phenacetin, 0.25 Gm of acetylsalicylic acid and 0.02 Gm of codeine—*Pharm Zentralh*, 76 (1935), 227 (E V S)

Tussipebt Tablets (P Beiersdorf and Co, Vienna), in packages of 32, contains amino benzoic acid ester, menthol, anisol, primula saponin—*Pharm Post*, 68 (1935) 213 (H M B)

Tutopon (Bayer) ampuls, suppositories, tablets and solution contain 1-2% total alkaloids of opium—*Pharm Post*, 68 (1935), 210 (H M B)

Urginin (Calco Chemical Co), formerly known as **Scillonin**, is a cardiac tonic derived from two of the active glucosides of squill and the clinical value of the product has been thoroughly demonstrated in the treatment of decompensations, cardiovascular renal disorders—*Drug and Cosmetic Ind*, 36 (1935), 775 (H M B)

Uric Acid Cachets (Pharm Handelsgesellschaft m b H, Dusseldorf) is a yellow colored powder consisting of oxgall (as dry substance 50%), phenylquinoline carbonic acid 30%, hexamethylenetetramine 20%. It is used for rheumatism gout etc—*Pharm Monatsh*, 16 (1935), 98 (H M B)

Vermitrapp-Suppositories (Dr Schmidtsche Apotheke Inh Otto Trapp, Tubingen), a vermifuge, containing iodoform naphthalene thymol and cocoa butter—*Pharm Zentralh*, 76 (1935), 307 (E V S)

Wolarin Tablets (Borussis-Apotheke, Ed Patermann, Berlin-Schöneberg) contain in each tablet ext valerian (5%), calcium carbonate (1%), quinine hydrochloride (0.5%) menthol (0.1%), phenacetin (25%) and acetylsalicylic acid (68.4%). It is used for influenza, rheumatism, gout ischias, head and nerve pains—*Pharm Zentralh*, 76 (1935), 339 (E V S)

BACTERIOLOGY

Antipneumococcic Serum—A New Method of Titration of, by the Neutralization of the Antibodies in Vitro Assay methods *in vivo* are inconvenient and lacking in precision. Methods *in vitro* for the assay of anti-toxic serums do not give a true measure of the therapeutic activity. References to these are cited. The principle of the new method is to find the maximum volume of serum which a known weight of dry antigen is able to deprive of its antibodies. A constant weight of pneumococcic antigen is placed in contact with varying volumes of serum. The presence of antibodies in the centrifuged liquid is detected by the addition of pneumococcic gum which causes precipitation. The method is given in detail. The authors hope to apply the method to those serums such as antistreptococcic, antimeningococcic and antigonococcic which are impossible or difficult to test with animals—LOUIS CORONI and JACQUES POCHON *Compt rend*, 200 (1935) 2039 (G W H)

Disinfection—Fallacies and Dangers in Attempted Chemical According to the author iodoform is not a disinfectant at all. It can be added to bacterial cultures in quantity without in any way interfering with their growth, if it is placed in the bottom of a tube of broth, colonies of streptococci will grow on it. Mercurochrome is a grossly overrated substance which deceives by its color just as iodoform deceives by its smell. Results of experiments show that concentrations of mercurochrome necessary for bactericidal action are very much greater than those indicated by the original work of Young, whose results are vitiated by the fact that he made his test dilutions in acid urine. The following is a statement of the concentrations of mercurochrome which, according to different observers will or will not kill *Staphylococcus aureus*

Observer	Dilution	Conditions	Time of Exposure	Result
1	1 10,000	In urine	15 mins	Killed
2	1 400	In blood	24 hours	Failed to kill
3	1 400	In broth	24 hours	Failed to kill
4	1 50	In water	10 mins	Failed to kill
5	1 100	In water	15 mins	Failed to kill

Among disinfectants most resistant to interference by organic matter are phenol and cresols, which are consequently well suited for disinfecting excreta, and flavine is one of the most reliable antiseptics for many surgical purposes. On the other hand, the emulsion of acriflavine (B. P. Codex 1934) is an example of the incorporation of a disinfectant in an unsuitable vehicle. This emulsion can be poured in quantity on to fluid culture media and left there indefinitely without interfering with bacterial growth. The emulsion is so constituted that none of the flavine diffuses into a watery medium in contact with it, unless the two are briskly shaken together in a corked tube. Most disinfectants are liable to cause subtle and invisible damage to the tissues if only by immobilizing leucocytes, but some destroy tissue to an extent which can be seen and felt. Among the latter we have principally to consider disinfectants of coal-tar origin. Phenol is the most caustic of all substances which have been used as disinfectants in medicine. The cresols are somewhat less toxic and rather more bactericidal. Some bacteria such as the tubercle bacillus and sporing bacteria, are more resistant than others to any disinfectant. But apart from these special types, there is endless and wide variation in the susceptibility of different bacteria to the action of a single disinfectant: these variations are not the expression of a general vulnerability in the bacterial cell, since a micro organism which is easily killed by one disinfectant may be almost indifferent to another. It is suggested that a weak solution of a disinfectant may stimulate bacterial growth, and this is particularly likely when disinfectants are injected intravenously in septicemia. If so, ineffective measures are not merely indifferent: they may be dangerous.—L. P. GARROD
Pharm. J., 134 (1935), 323 (W. B. B.)

Mold Fermentations—Apparatus for the Application of Submerged, under Pressure. A new apparatus is described. It consists essentially of a revolving drum equipped with internal buckets and baffles and provided with means for the introduction and removal of air under pressure.—H. T. HERRICK, R. HELLBACH and O. E. MAY. *Ind. Eng. Chem.*, 27 (1935), 681 (E. G. V.)

4'-Sulfamido-2,4-diamino-azobenzene Hydrochloride—Curative and Preventative Action of, in Experimental Streptococcus Infection. Mice intraperitoneally infected with *Streptococcus hemolyticus* survived six days when 4' sulfamido 2,4-diaminoazobenzene hydrochloride (rubiazol) was given *per os* in a single dose of 0.005 Gm for a 20 Gm mouse. Survival was extended to from 10 to 17 days when the same dose was given subcutaneously. Some curative action was shown by repeated injections. Rubiazol shows a preventative action if the infection takes place within 48 hours after the preventative treatment. It stops the multiplication of the streptococci without total destruction of the microbes.—CONSTANTIN LEVADITI and ARON VAISMAN. *Compt. rend.*, 200 (1935), 1694 (G. W. H.)

BOTANY

Acorus Calamus—Seed and Seedling of. This species appears to be sterile in Europe where it has been naturalized. This is also true of plants introduced from Europe. In Minnesota where it appears to be native the plant fruits abundantly. The fruit is a 3 celled, gelatinous berry containing usually 5-7 orthotropous ovoid somewhat angled seeds pendant from an axillary placenta. The cylindrical embryo lies in the axis of the endosperm, which is surrounded by a thick callous perisperm. The seed coat is made up of a thin tough tegmen surrounded by a thicker testa. In germination, the tip of the cotyledon remains as an haustorial organ and lifts it into the air. The seedling immediately becomes green, develops absorbing hairs and is early independent. The single vascular bundle of the cotyledon passes directly down into one pole of the diarch root while the midrib of the first plumular leaf is directly continuous with the other pole.—MURREY F. BUELL. *Botan. Gaz.* 96 (1935) 758-765 (G. W. F.)

Brazilian Euphorbiaceæ—Essential Oils from. The N. O. Euphorbiaceæ is represented in Brazil by 62 genera and almost 900 species. The author describes a few of the species derived from recent research work.—F. W. FREISE. *Perf. and Ess. Oil Rec.*, 26 (1935), 219 (A. C. DeD.)

Cytisus Scoparius—Natural Distribution of, in Virginia with Special Reference to Soil Reaction. The plant was found to favor soil with a pH from about 6 to 6.7.—THOMAS W. TURNER. *Bull. Torrey Botan. Club.*, 62 (1935), 331-335 (G. W. F.)

Datura Stramonium and D. Metel—Fertilization of, in the Incompatible Cross. The fertilization process is discussed. The incompatibility is apparently caused by disintegration of

the cells of the endosperm and procumbry —SOPHIA SATINA and A F BLAKESLEE *Bull Torrey Bot. Club*, 62 (1935), 301-310 (G W F)

Drug Plants—Evaluation of Cultivated, in 1934 The experience resulting from the cultivation of domestic drug plants is described and the results of numerous determinations of the active principles of various plants are tabulated. Investigations show that peppermint leaves usually average 1.3-1.6% of oil, *Coriander sativum* 0.41-0.5%, Russian coriander 0.41-0.6% and Thuringer coriander 0.31-0.4%. In the alkaloid containing plants, belladonna leaves yielded 0.6-0.83%, hyoscyamus leaves 0.39-0.65% and stramonium leaves 0.44-0.75%. Both *Thymus vulgaris* and hyoscyamus yield a greater percentage of active principle before flowering than after flowering —K H BAUER *Pharm Zentrallh*, 76 (1935) 281 (E V S)

Drug Potency—Fluctuation of, during Growth The authors present a study of the factors affecting the quantity of active constituent of the following drugs: *Mentha piperita*, *Thymus vulgaris*, *Melissa officinalis*, *Digitalis lanata*, *Hyoscyamus niger* and *Datura stramonium*. The drugs were carefully collected at regular intervals, dried, assayed and the results graphed. A series of hot, dry, sunny days causes the ethereal oil content of the drugs to decrease, whereas similar weather causes an increase in alkaloidal and glycosidal content of the drugs. Similar studies applied to other drugs should lead to the cultivation of a better grade of drugs —O DAFERT, W HIMMELBAUR and K LOIDOLT *Scientia Pharm*, 6 (1935) 45 (M F W D)

Leaves A comparative anatomical study of various official leaf types including the functional aspects —H SOMMER *Pharm Zentrallh*, 76 (1935) 150, 159 (E V S)

Matricaria—Italian and Hungarian To discover the cause of the superiority of commercial Italian matricaria to the Hungarian drug, the author grew some from Hungarian seed side by side with some from Italian seed. The flowers were collected at the same time and dried under the same conditions. The Italian flowers yielded 0.7865% of a clear blue, well flavored essential oil, those from Hungarian seed yielded 0.469% of a brownish-green oil of not too pleasant an odor. He therefore concludes that the Italian and Hungarian plants are different varieties —G BISCARO *Boll chim farm*, 73 (1934), 758, through *Quart J Pharm Pharmacol*, 8 (1935), 138

Rhubarb—Culture of Chinese The cultivation of two species, *Rheum palmatum* (L.) Tsch and *R. cordifolium* nov spec, is described —A TSCHIRCH *Apoth Ztg*, 50 (1935), 42, through *Chem Abstr*, 29 (1935) 42

CHEMISTRY

GENERAL AND PHYSICAL

Medicinal Chemistry—Contributions of An outline of early and recent accomplishments and objectives of the future —C R ADDINALL *Ind Eng Chem*, 27 (1935), 533 (E G V)

Salt Hydrates—Vapor Pressure and Dehydration of Unstable Sodium Perborate A study is made of the factors influencing the rate of dehydration of salt hydrates. A partial explanation of the mechanism of dehydration is given, and equations are developed which give the rate of dehydration for hydrates having different rates of nucleus formation. The influence of temperature, air pressure, air velocity, depth of material and area exposed and size of particles on the rate of dehydration is evaluated. When sodium perborate is dehydrated at 50° to 60° C until there is a loss in weight equivalent to 3 molecules of water or 35.5% there is a gain in available oxygen up to 15.7% which corresponds closely to the expected 16.2%. By prolonging the dehydration at 60° to 65° C, or on heating to a higher temperature for a shorter time, the color of the residue changes to a weak yellow at lower temperatures and to a definite yellowish color at higher temperatures. There is some loss in oxygen and water, and when the product is put into water, gaseous oxygen is evolved. The violence of the action and the amount of oxygen evolved depend upon the time and temperature of heating —T I TAYLOR and G G TAYLOR *Ind Eng Chem*, 27 (1935) 672 (E G V)

INORGANIC

Mercury—New Method for Its Dry Purification A current of cotton-filtered air at atmospheric temperature is passed through the mercury for 4 to 5 hours. On leaving the mercury the air is cooled and passed through a tower of activated bone char containing iodine which completely absorbs entrained mercury. This gives a technically pure product suitable for gages, etc. To obtain a product suitable for thermometers (at least 99.6% purity), continue passing air and

gradually raise the temperature to 105° C in 2 hours, keep at this temperature for at least 15 minutes, and filter repeatedly through paper cones perforated with a fine hole C P mercury has a brilliant surface, when 100 cc are shaken for 15 minutes in a white 1-liter flask the surface must not be covered with a dull film The method is economical, simple and free from danger, and the mercury retained by the char or the impurities can be recovered easily—ZIENER *Glas U Appar.* 15 (1934) 187-189, through *Chimie & Industrie*, 33 (1935), 1118 (A P C)

ORGANIC

Alkaloids

Apoquinine and Apoquinidine Demethylation of quinine with ether aluminum chloride or 60% sulphuric acid yields so called "apoquinine," which the authors have found to be mainly a mixture of apoquinine and chlorodihydroapoquinine This mixture forms a dihydrochloride and a zincchloride, the latter on repeated recrystallization from concentrated hydrochloric acid becomes constant in composition and physical properties By repeated recrystallization of crude apoquinine and its acid diamsoyl *d*-tartrate from methyl alcohol and acetone, pure chlorodihydro apoquinine and apoquinine free from chlorine have been obtained Well crystallized and apparently pure quinidine of commerce usually contains 20 to 30% of dihydroquinidine Using specially purified quinidine of 99.5% purity the authors have obtained, by demethylation, two new substances—isoapoquinidine, $C_{15}H_{22}O_2N$ colorless hexagonal prisms melting point, 245° C $[\alpha]_D^{15.0}$ 12.6° ($c = 1$ in alcohol) or +25.6° ($c = 0.78$ in *N*/10 sulphuric acid), and apoquinidine a dextrorotatory crystalline substance yielding well crystallized salts, which is difficult to purify and is still under investigation Formulae and physical constants of a number of bases and their salts are given—T A HENRY and W SOLOMON *J Chem Soc Lond* (1934) 1923, through *Quart J Pharm Pharmacol* 8 (1935) 116

Corynanthine—Constitution of Corynanthine and yohimbine are *cis-trans* isomers The methyl and ethyl esters of the base obtained by the saponification of corynanthine with potash, as well as the apo derivative, are identical with the corresponding derivatives prepared from yohimbine The author suggests that the name pseudo corynanthine applied by Raymond Hamet (*Compt rend*, 199 (1934), 1658) to the base obtained by saponifying corynanthine with alkali be stricken from the literature—CAESAR R SCHOLZ *Compt rend* 200 (1935), 1624 (G W H)

Ergobasine, New Water-Soluble Alkaloid of Ergot About 0.06 Gm of this new alkaloid ($C_{14}H_{23}N_3O_2$) can be obtained from 1 Kg of commercial ergot It has been possible to extract a few grams of pure crystalline ergobasine in the commercial manufacture of ergotamine and ergotoxine It is obtained by extracting finely powdered ergot with water and exhausting the aqueous extract with chloroform from which the ergobasine crystallizes upon concentration and can be purified by recrystallization from trichlorethylene or benzene It can also be obtained by dissolving a mixture of the total alkaloids of ergot in chloroform, when a certain concentration is reached the ergobasine crystallizes out It crystallizes in right angled prisms The aqueous solution (1-200 or 300) is alkaline to litmus with an intense bluish fluorescence It is very soluble in ethyl and methyl alcohol, readily soluble in ethyl acetate, 1-5000 in cold and 1-750 in hot chloroform Recrystallized from alcohol and dried to constant weight it softens at 159° and decomposes at 162° A 0.25% aqueous solution has a rotation of $[\alpha]_D^{20} = +90^\circ$ The solutions are sensitive to light and air which without doubt accounts for the variation in the strength of the galenic preparations While the reactions with the general alkaloidal reagents are positive, it can be distinguished from ergotamine by the concentrations necessary These two alkaloids are the only two extractives from ergot to give crystalline salts Ergobasine merits a thorough pharmacological study, it bears a resemblance to the ergometrine of Dudley and Moor but is sharply distinguished from the latter being dextro while ergometrine is levogyrate—ARTHUR STOLL and ERNEST BURCKHARDT *Compt rend* 200 (1935) 1680 (G W H)

Ergometrine—Isolation of Ergometrine discovered by Dudley and Moor (*Brit Med J*, 1 (March 16 1935), 521) is appreciably soluble in cold water and moderately soluble in chloroform, benzene and dichloro-ethylene, from which it may be recrystallized The specific rotation of the material recrystallized from benzene in 0.1% solution in chloroform is -45 degrees and a provisional analysis gives the values C 71.46, H 7.38, N 11.66% Ergometrine gives the dimethyl

aminobenzaldehyde and glyoxylic acid color reactions common to the known ergot alkaloids. The long delay in the discovery of ergometrine is due to its having no distinctive pharmacological properties, so far as has yet been determined, and the chemical isolation has been dependent on clinical tests throughout. The importance of ergometrine is obvious enough, but certain conclusions drawn by the discoverers seem to be too hasty. The action of ergometrine is sudden and vigorous, and subsides in two hours, it cannot maintain continuous contraction when given only three times a day. The action of ergotamine, on the other hand, is much more persistent. Dudley and Moir argue that since the effect of a single dose of ergotamine administered by mouth, even as large as 2 to 3 mg, does not begin for thirty five minutes, and is relatively feeble, oral administration of ergotamine is useless. But oral administration of ergotamine three times a day for several days may be far from useless, the full effect may not be obtained for three or four hours after the first dose, but thereafter it may be maintained by the repeated doses throughout the puerperium without interruption. To suggest, as Dudley and Moir do, that ergotamine may possibly be undesirable in preparations for oral use is surely against the weight of the present evidence.—J H BURN *Pharm J*, 134 (1935), 357 (W B B)

Holarhena Antidysenterica—A New Alkaloid from the Bark of The drug is used in Burma as a remedy for dysentery and as a febrifuge under the name of lettok. The alkaloidal content of the bark was 1.2 to 1.36%. The alkaloids were extracted with cold dilute hydrochloric acid, cold alcohol, and hot alcohol. A second extraction with alcoholic ammonia yielded an extra 0.1 to 0.2%. When the alkaloids were separated in the usual manner an alkaloid ($C_{17}H_{15}O_2N$) giving a hydrochloride soluble in water, but sparingly soluble in hydrochloric acid was found. The base purified through the hydroiodide (m.p. 256°-decomp) was obtained as a light brown powder (m.p. 350-352°). It does not appear to be identical with any of the alkaloids previously described as present in the bark and the name *lettocine* is suggested. It appears to be a tertiary base and to contain no hydroxyl groups. The amount present in the bark is less than 0.1%. No alkaloids were found in the latex, but alcoholic extraction yielded two crystalline solids of the resinol type. The chemical constants of alkaloids previously reported are reviewed.—D H PEACOCK and J C CHOWDHURY *J Chem Soc* (1935), 734-735 (G W F)

Ipecac Alkaloids—Distribution of, in the Rubiaceae. The roots of *Remyia Amazonica* Schum. yield 0.75-0.82% of emetine, 0.43-0.62% of cephaeline, 2.22-3.18% of oleoresin (a skin irritant and drastic), 0.035-0.055% of ethereal oil, 1.65-1.92% of fatty oil, 1-2.2% of saponin and 14-18% of tannins. It is also known as *Poaya brava*. In *Ferdinandusa Elliptica* Schum. var. *Belemensis* Ducke, the outermost roots yield 0.88-0.96% of emetine, 0.26-0.33% of cephaeline, 0.02-0.035% of psychotrine and a trace of ethereal oil. The plant grows along the shores of Paraguay and Peru where it is used for dysentery. *Tocoyena Longiflora* Aubl. a native of French Guiana and Brazil, contains in its roots 1.31-1.66% of emetine, 0.62-0.68% of cephaeline, 0.02-0.08% of psychotrine and some oleoresin. *Caperona Decorticans* Spruce, the roots of which are found in many patent medicines, yields 0.68% of emetine, 0.74% of cephaeline, 0.11% of psychotrine, 5-8% of a yellowish red coloring principle and about 11% of tannins. The yellowish white bark of *Bohrrospora Corymbosa* Hook, also known as *Ipeca lisa*, contains 1-1.35% of emetine, 0.10-0.22% of cephaeline, and a trace of psychotrine. The stem bark of *Halla Illustris* (Vell.) Schum., an epiphyte, yields 1.11-1.37% of emetine without any accompanying alkaloids. A short botanical description and the South American habitats of the above plants are included.—FRIEDRICH W FRIESE *Pharm Zentralh*, 76 (1935), 223 (E V S)

Kola-Nut—Cultivated in Brazil. The fresh Brazilian kola nut contains water 40, caffeine 1.41, theobromine traces and mineral salts 1.96%. Its caffeine content is about the same as that of African nuts.—V VARGAS *Bol. assoc. brasil. pharm*, 15 (1934), 250, through *Chem Abstr*, 29 (1935) 4129

Lévornine (Adrenaline) A review of the methods of preparation of natural and synthetic adrenaline. The assay and standardization of adrenaline are discussed.—LAPINÉ and LAVOYE *J pharm Belg*, 17 (1935) 485-488, 507-509 (S W G)

2-Phenylquinoline-4-carboxylic Acid—Quinine Salt of A tasteless product is obtained by preparing the salt as described in German Patent 563,457 but at any convenient temperature, and then washing it at 60-70° with water, benzene or other liquid in which it is also sparingly soluble.—R and O WEIL, chem.-pharmazeutische Fab. German Pat. 611,235 (Mar. 25, 1935), through *Chem Abstr*, 29 (1935), 4134

Physostigmine—Synthesis of II It has already been reported that desoxydinoreseroline and desoxy-9-methyldinoreseroline are obtained by reacting Grignard compounds of tryptamine or α -methyltryptamine with methyl iodide. By using 5 ethoxy- and 5 methoxytryptamines, it has now been found, dinoreserthole and -methole, which serve as starting materials in the synthesis of eserine, may be obtained. Optical resolution of dinoresermethole was realized by means of *d* bromocamphorsulphonic acid and *d* tartaric acid. Since methyl- β (5 alkoxy 3 indolyl) ethyl amine may be the starting point for the synthesis of eserine, this possibility was tested by mono-methylating tryptamine. On reacting the methyl iodide with tryptamine, only the quaternary iodide was obtained. Then benzylidenetryptamine was reacted with methyl iodide, but instead of the expected secondary base, two new substances were separated: 3-phenyl-3,4,5,6 tetrahydro-4-carboline and 3-phenyl-4-methyl-3,4,5,6 tetrahydro-4-carboline-iodomethylate.—T. HOSHINO and Y. KOTAKE. *Ann.*, 516 (1935), 76, through *Squibb Abstr. Bull.*, 8 (1935), A-594.

Senecio—Alkaloids of Barger, *et al.*, isolated an alkaloid related to senecifoline and seneci folidine, from so called *Senecio latisfolius* and from accurately identified *S. retrorsus* D.C. The compound was identical with the retrorsine (I) of Manske, melting point, 212° (Manske, 214–215°, cor.) readily soluble in alcohol, chloroform, slightly soluble in water, acetone and ethyl acetate, and hardly soluble in ether, and gave a monophenylcarbamate, melting point, 200–202°, a nitrate, melting point, 145°, a methiodide, melting point, 260° and a perbromide. Acid or alkaline hydrolysis of I yielded retronecine (II) and retronecic acid (III). II, melting point, 121–122°, contained neither OCH_3 nor N-CH_3 groups, did not react with nitrous acid and formed a quaternary iodide with methyl iodide, probably being a tertiary base. It contained two reactive hydrogen atoms and gave a diacetyl derivative when boiled with acetic anhydride, which when catalytically reduced lost one acetoxy group and took up four hydrogen atoms. The authors could not demonstrate a ketone group in II. Catalytic reduction of I, II and the diacetyl derivative of II (IV) with platinum oxide gave rapid absorption of four hydrogen atoms. With palladium and hydrogen, I and IV gave similar results but II yielded a substance which treated with mineral acid gave an analogue of pyrrole red and on further reduction gave retronecanol (V). Oxidation of V gave a compound with a methiodide of melting point, 292–295° C and was presumably derived from an acid $\text{C}_8\text{H}_4\text{NCO}_2\text{H}$ (picolinic?), but more material is required for identification. III was a dihydroxy dicarboxylic acid, $\text{C}_{10}\text{H}_{10}\text{O}_6$, melting point, 177°, and when heated with anhydrous oxalic acid for several hours, yielded a lactone acid, melting point, 181–183°. II and III may have been combined in I by two or by one ester linking, in the latter case the second molecule of water used up in hydrolysis would hydrolyze a lactone group.—G. BARGER, T. R. SESHADRI, H. E. WATT and T. YABUTA. *J. Chem. Soc.* (Jan 1935) 11, through *Squibb Abstr. Bull.*, 8 (1935), A 598.

Yohimbine Commercial preparations of yohimbine hydrochloride (I) were found to consist mainly of isoyohimbine (II) melting point, 239–240°, $[\alpha]_D$ in 1% pyridine = 108.5°. II was best obtained by heating I in aqueous alcoholic solution with tartaric acid, II tartrate, melting point, 252–253°, II hydrochloride, melting point, 298–299°. II was converted to isoyohimbic acid (III), melting point 268–269° by treating II with potassium hydroxide, acidifying with hydrochloric acid, concentrating and precipitating with ammonium hydroxide. III methyl ester, melting point, 239–240°, III ethyl ester, melting point, 202–204°. Yohyrine, $\text{C}_{19}\text{H}_{21}\text{N}_2$, melting point, 217–218°, was hydrogenated in the presence of platinum oxide to decahydroyohyrine, $\text{C}_{19}\text{H}_{29}\text{N}_2$, melting point, 228–229°, picrate, melting point, 195–196°. Reduction of tetrahydroyohyrine gave octahydroyohyrine, $\text{C}_{19}\text{H}_{27}\text{N}_2$ (yobine), melting point, 177–178°, picrate, melting point, 220–221°, dehydrogenation with selenium gave yohyrine.—J. P. WIBAUT and A. J. P. GASTEL. *Rec. trav. chim.* 54 (1935) 85, through *Squibb Abstr. Bull.*, 8 (1935), A 678.

Essential Oils and Related Products

Aniseed Oil—Preliminary Report on Study of, from Kuangsi The seed of *Illicium verum* Hook produced in Kuangsi province, China, known as *Fructus anisi Stellati*, contains 9% essential oil of which 92% is anethole. This essential oil has the following physical constants: d_4^{25} 0.970–0.970, n_D^{25} 1.5437–1.5407, α_D +1.5°, melting point 19.5–20°, solidifying point 15.5°.—CHUN HSIE WANG. *Chem. Ind. (China)*, 9 (1934), 27, through *Chem. Abstr.* 29 (1935), 4123.

Citronellol-Rhodinol Isomerism—Study of, by Means of Raman Spectrography The Raman spectra, specific gravity, refractive index and specific rotatory power were determined for

citronellal (I) and citronellal (II) (both from Java oil of citronella), for citronellol obtained by reduction (a) of ethyl citronellate (III), (b) of citronellal by aluminum butyrate (IV), and (c) over nickel of the mixture of citronellal and geraniol from oil of citronella with the citronellol therein (V), and of rhodinol from Reunion oil of geranium purified by treatment with benzoyl chloride (VI). I, III and VI are mixtures of the α and β forms, β preponderating, no α is detectable in II, IV and V—Y. RENE NAVES, GEORGES BRUS and JEAN ALLARD *Bull Inst Pin*, (1935), 52-53 (A P-C)

Madagascar Clove Oil Survey of Primary Production The oil produced in Madagascar is derived mainly from clove leaves, only a small extent from clove stems. It is estimated that there are about 170 stills operating, about 100 in the Soanierana District and 70 in Sainte Marie. A table showing the exports of Madagascar clove oil is included. Supplies of leaves are obtained by cutting out the growing top of the clove tree to a depth of about 3 feet, thus leaving a cup-shaped depression at the top of the tree. The oil from the distilleries is transported in large glass bottles, and purchased by European exporters or Chinese traders. Good Soanierana oil is reported to contain 85% eugenol—ANON *Perf and Ess Oil Rec*, 26 (1935), 204 (A C DeD)

Perfume Chemistry—New Procedures in A review—A. LEWINSON *Riechstoff Ind Kosmetik*, 10 (1935), 85-88, 104-106 (H M B)

Spirit of Turpentine—Oxidation of Tests were carried out on the oxidation of the tail fraction of spirit of turpentine in presence of galvanized iron, zinc and iron, respectively, as catalysts, and on American spirit of turpentine in presence of galvanized iron. The results confirmed that oxidation proceeds differently in presence of iron and of zinc as catalyst. In presence of zinc formic acid is the principal product formed, oxidation products that are present in old spirit of turpentine have long been known to act as catalysts, and having the same action as zinc. At high temperature (during distillation) their action is instantaneous and is accompanied by liberation of water. Use of galvanized containers for spirit of turpentine is therefore quite inadvisable. In presence of iron oxidation produces mainly resinic acids, which are partly insoluble in the liquid—J. TERPUGOFF *Bull Inst Pin* (1935), 6-10 (A P C)

Sweet Basil Oil A discussion of the botany, cultivation, distillation and chemical characteristics of oil of sweet basil (*Ocimum basilicum* L.) and a common adulterant, 'Reunion basil oil'. Chemical constants for genuine sweet basil oil were found to be sp gr (15° C) 0.914-0.935, opt rotat $-10^{\circ}50'$ to $-4^{\circ}8'$, sapon value 5.1-14.5, refrac index 1.4869-1.4929, alcohol content 33-41%—ERNEST S. GUENTHER *Am Perfumer*, 30 (1935), 183-185 (G W F)

Fixed Oils, Fats and Waxes

Fats—Antioxidants and the Autoxidation of Methods are described for estimating the length of the induction period of lard and lard cod liver oil mixtures by oxygen absorption for measuring the minute pressure changes occurring in a closed system during and immediately following the induction period, and for determining the peroxide content of autoxidizing fats by slight modifications of the usual thiosulphate titration procedures. The prolongation of the induction period by some natural antioxidants and several phenolic compounds is proportional to the amount used. At the end of the induction period the level of peroxide in lard or lard cod liver oil mixtures is fairly uniform irrespective of the length of the induction period or of the original peroxide content. With one natural inhibitor there seemed to be a mutual destruction of antioxidant and active peroxides. Some of the difficulties in obtaining reproducible data are discussed—R. B. FRENCH, H. S. OLCOTT and H. A. MATILL *Ind Eng Chem*, 27 (1935), 724 (E G V)

Halibut Liver Oil—Preservation of, with Hydroquinone Presence of an anti oxidant in cod liver oil retards absorption of oxygen, prevents loss of vitamin A and development of mal-flavors. Since halibut liver oil has a high concentration of vitamin A and requires special refining to free it from objectionable natural odor and taste, protection of an anti oxidant is important. The present report shows that hydroquinone greatly retards absorption of oxygen and loss of vitamin A in halibut liver oil. Experimental details reported include type of oils studied, preparation of the samples, testing of samples, vitamin A color unit, technique of the antimony trichloride vitamin A color test. Several tables and several graphs show results of experiments. Oils with out hydroquinone differ in susceptibility to oxidation, especially in the 'air' experiment. The same oils with hydroquinone do not differ appreciably in susceptibility to oxidation. An oil with 0.03% hydroquinone is quite resistant to oxidation. Since maleic acid inhibits oxidation of un-

saturated fats, oils, fatty acids and substances containing fatty material and tend to become rancid, a series of experiments was set up using it, but results were negative. The authors conclude that hydroquinone retards absorption of oxygen by refined halibut liver oil from air and from pure oxygen, and retards deterioration of vitamin A, as shown by color test and biological test—W S JONES and W G CHRISTIANSEN *J Am Pharm Assoc*, 24 (1935), 465 (Z M C)

Glycosides, Ferments and Carbohydrates

Folinerin A crystalline chemically uniform glucoside with complete digitalis action has been isolated from oleander leaves. It crystallizes from dilute alcohol in prismatic needles, melting point 249°, shows a specific rotation of $[\alpha]_D^{20}$ 45.95°, has an empirical formula $C_{27}H_{40}O_8$ (molecular weight 582) is relatively stable to dilute acids and seems to be related to Windaus "oleandrin," if not identical with it. On splitting off the sugar from this glucoside, a formerly unknown aglucone, oleandrigenin, $C_{25}H_{38}O_6$, is formed. This is isomeric with gitaligenin and like it, splits off water under energetic acid action to form digitaligenin, $C_{23}H_{36}O_5$. While in general the aglucones are much less active than the glucosides, in the case of this new glucoside, folinerin, its aglucone, oleandrigenin is superior to all the aglucones of the digitalis group in pharmacological activity. The cat unit (Hatcher Magnus method) is 0.25 mg/Kg. Folinerin is very active, a dilution of 1-500,000 producing tonic stoppage of isolated frog hearts and other typical actions of digitalis. On the intact heart, 1 mg folinerin is equivalent to 1200 frog doses. These values place it in the strophanthin group. The cat unit of folinerin corresponds to 0.24 mg/Kg (Hatcher Magnus). In cats the lethal dose is 0.2 mg/Kg subcutaneously, rectally 0.24 mg/Kg. The fact that the lethal dose with subcutaneous or rectal administration is so near the intravenous value (0.12 mg/Kg) points to the marked resorbability of the glucoside. This is in agreement with the markedly small molecule of folinerin. With regard to oral administration, it is of great importance that the glucoside is resorbable and resistant to dilute acids. As regards the cumulation of folinerin, it is easier to reverse its tonic stoppage of the isolated frog heart by washing than is the case with digitoxin. Furthermore, after a preliminary dose, the additional dose required to produce death is larger for folinerin than for digitoxin. Folinerin is very stable, an aqueous alcoholic solution showing no change in activity after three years' storage. In man, the glucoside is tolerated without any sequelae whatsoever, to the extent of 1 mg which is considerably above the therapeutic dose—F FLURY and W NEUMANN *Klin Wochschr* 14 (1935), 562, through *Squibb Abstr Bull*, 8 (1935), A 764.

Glycyrrhizin Dilute alkali extract of licorice is treated with magnesium or calcium salt until there is no further precipitation. From the filtrate glycyrrhizin is separated by acidifying—KANEGAHUCHI BOSEKI K K (Toyo Ito, inventor) Japan 109,401 (Jan 29 1935), through *Chem Abstr*, 29 (1935), 3784.

Other Plant Principles

Calumba Root—Bitter Principles of The bitter principle, chasmanthin, a crystalline substance, $C_{20}H_{32}O_7$ has been isolated not only from the calumba root but from another calumba principle, columbin, on treatment with acids or alkalis. Chasmanthin is present in a high melting (265°) and low melting (212°) form, both of which can be transformed into the form usually found in the root, i.e., melting at 246°. Methylation of columbin as well as that of chasmanthin yields chasmanthin monomethyl ether. Columbin, $C_{22}H_{34}O_7$, melting point 182° (decomposition) is optically inactive as is chasmanthin. It probably contains a β lactone group, while chasmanthin seems to have two lactone rings. The thermal decomposition of columbin was studied—K FEIST, P RINTELEN and E KUNTZ *Ann*, 517 (1935), 119, through *Squibb Abstr Bull*, 8 (1935), A-729.

Hai-jen-tsao (Digenea Simplex Ag)—Chemical Study of Hai jen tsao, a variety of marine alga has long been used in China as a vermifuge. The algaenic acid extracted by 2% sodium carbonate contains uronic acid and either glucuronic or mannuronic acid. The boiling water extract yields galactan, D-pararabin, a small amount of alkaloids and fucoidin which are subjected to detailed examination. It contains 0.20% of iodine—CHIH-FANG HSU *Science (China)* 18 (1934), 1418, through *Chem Abstr* 29 (1935), 4129.

Stramonium—Constituents of European Datura, Cultivated in China From air dried European *Datura stramonium* cultivated in China there were isolated, besides hyoscyne, hyoscy

amine and atropine, two neutral principles to the extent of 0.3%, *datugen* $C_{13}H_{10}O_2$, melting point, 295° , α 41.60° and *datugenin*, $C_{16}H_{12}O_6$, melting point, 265° , α 75° —T Q CHOU *Chinese J Physiol*, 9 (1935), 77, through *Chem Abstr*, 29 (1935), 4130

Valerian—Presence of α -Pyrrol Methyl Ketone in Stabilized The residues (2770 Gm) from the fresh rhizomes and roots of valerian stabilized with ethyl alcohol were employed. The filtrate obtained after distillation of the ethyl alcohol was washed with ether which left an acid residue with an odor of valeric acid, was neutralized with sodium carbonate (25%), and extracted with ether (357 Gm). The ether extract upon evaporation yielded a brown semi liquid mass, which was saponified with alcoholic potassium hydroxide (10%). The solution was concentrated, taken up with water, extracted with ether and from this residue (107 Gm) was obtained a liquid (10%) b_D^{25} $60-125^\circ$, which after further fractionation yielded a yellowish liquid (16%) b_D^{25} $68-73^\circ$, producing upon standing 0.2 Gm of a solid, crystallized from petroleum ether, melting at 90° , soluble in water and organic solvents. This was identified as α pyrrol methyl ketone by its oxime (melting point $144-145^\circ$), phenylhydrazone (melting point $143-144^\circ$) furacrylic derivative (melting point, $134-135^\circ$) which melting points agree well with those obtained for the derivative from the synthetic product —E CIONGA *Compt rend*, 200 (1935) 780, through *Chem Abstr*, 29 (1935), 3770

Unclassified

Arsenamides Compounds Containing the As-N Linkage Those who have investigated the reaction between arsenous halides and amines have given conflicting reports. These are discussed briefly. Work described in the present paper indicates that the reaction is more complex than previous work indicated. The earlier conflicting reports are due to failure to isolate all the products of the reaction. In nearly all reactions two or more products were obtained or indicated. The reaction between an arsenous halide and an amine takes place according to the following equations

- 1 $AsX_3 + RNH \rightarrow X As NHR HX$
- 2 $X_2AsNHR HX + RNH \rightarrow X_2AsNHR + RNH HX$
- 3 $AsX_3 + 2RNH \rightarrow XAs(NHR HX)$
- 4 $XAs(NHR HX)_2 + 2RNH_2 \rightarrow XAs(NHR)_2 + 2RNH HX$
- 5 $AsX_3 + 3RNH \rightarrow As(NHR HX)_3$

The course of the reaction is influenced by order of mixing strength of base and the arsenous halide used, possibly also certain steric effects. Under these varying conditions $As(NHC_2H_5 \cdot HCl)_3$, $Cl_2AsNHC_2H_5$, $As[N(CH_3)_2C_2H_5 HCl]_3$ were obtained. In addition to the arsenic compounds there is always a large amount of ammonium halide formed. Several types of compounds have been isolated. The type $XAs(NHR HX)$ and $As(NHR HX)_3$ are high melting solids, soluble in water, usually with decomposition and insoluble in organic solvents. They resemble ammonium halides in properties. Compounds of the type X_2AsNHR are high boiling liquids or low melting solids. They fume in the air and are decomposed violently by water. The name "arsenamides" is suggested for compounds containing the As-N linkage. So the following compounds prepared by the author are named $C_2H_5(I)As \cdot NHC_2H_5$ aniline ethylthioarsenamides, $Cl_2AsN(C_2H_5)_2$ diethylaminedichlorarsenamide, $As(NC_2H_5)_3 HCl$, piperidine arsenetriamides trihydrochloride, $ClAs(NHCH_2CH_2NH HCl)_2$ ethylene diamine chlorarsendiamide dihydrochloride. Experimental work is reported and each of eleven reactions discussed in detail —G O DOAK *J Am Pharm Assoc*, 24 (1935), 453 (Z M C)

3,3'-Bis-(Azometa-Phenylenediamine)-4,4'-Dihydroxyarsenobenzene and 3,3'-Bis-(Azo-2,6-Diaminopyridine)-4,4'-Dihydroxyarsenobenzene—Preparation and Properties of Since it is known that certain azo dyes penetrate tissue readily and also that some have a definite trypanocidal action, it was decided to prepare some azo dyes from arspenamine base by diazotizing it and coupling with diamines. Arsono and arsono azo compounds have been described and some patents have been issued but none are of the type prepared by diazotizing arspenamine and coupling with metaphenylenediamine and with 2,6-diaminopyridine. The two substances prepared are named in the title and have the following structural formulas

(I)

(II)

Aqueous sodium hydroxide solutions of these compounds, injected intravenously into albino rats stained conjunctiva ears and abdominal cavities in the characteristic manner. Both compounds were much more toxic than other arsenphenamines. The sodium salt of I was bacteriostatic to *B Typhoid* and *B Staphylococcus* in concentrations of 1-20,000. The free base was only slightly soluble in water but a saturated aqueous solution was bacteriostatic to both *B Typhoid* and *B Staphylococcus*. Both compounds seem too toxic for therapeutic use. Details of the experimental work are reported. Results of bacteriostatic and germicidal tests are tabulated—A E JURIST *J Am Pharm Assoc* 24 (1935) 457 (Z M C)

5,5-Diphenylbarbituric Acid The compound, which cannot be prepared by the conventional method, was obtained in small yield along with a high melting, unidentified product, by the condensation of benzene with alloxan by means of sulphuric acid. It was tested intraperitoneally on rats and was found to be effective only in doses 6-8 times the effective dose of luminal. The effective doses invariably caused death—S M McELVAIN *J Am Chem Soc*, 57 (1935), 1303 (E B S)

BIOCHEMISTRY

Barbituric Acid Derivatives—Determination of, in Urine Fifteen to twenty cc of urine are boiled with 0.2 Gm. norite and centrifuged warm. The clear supernatant liquid is decanted and the residue collected on a filter and dried. The residue is then warmed with 3 to 4 cc of absolute alcohol and 5 cc of chloroform and filtered. Two cc of this filtrate is cleared with absolute alcohol. 20 drops of 1% solution of cobalt nitrate in absolute alcohol and several drops of a 1% solution of potassium hydroxide in absolute alcohol added. In the presence of barbituric acid derivatives a blue color appears. Morphine, apomorphine and eukodal give similar reactions—MOHRSCULZ *Munch med Wschr* No 18, through *Pharm Weekblad*, 72 (1935), 696 (E H W)

Benedict's Test—Modification of This method for the rapid determination of sugar in urine, is based on the depth of color of the filtrate obtained after heating 5 cc of Benedict's qualitative reagent with 0.5 cc of urine in a boiling water bath for five minutes. The color of the filtrate is compared with standards. If the urine contains 2.0% of glucose the 5 cc of reagent is just decolorized and the filtrate is colorless. If the presence of 0.4% of glucose in the urine would result in the decolorization of 1 cc of the reagent. The standard color for this amount of sugar is obtained by dilution of 4 cc of the reagent to 5.5 cc with water. A series of standards is prepared by diluting decreasing volumes of the reagent to 5.5 cc, each decrease of 1 cc of reagent will correspond to an increase of 0.4% of glucose in the urine. The accuracy obtained by this method is sufficient for clinical purposes—J FINE *Brit Med J*, 11 (1934), 167, through *Quart J Pharm Pharmacol*, 8 (1935) 133

Duodenin—Insulotropic Hormone of Intestinal Mucosa Extracts of the mucosa of the duodenum and the proximal part of the jejunum contain a substance 'duodenin,' which stimulates the secretion of insulin from the pancreas. Injected subcutaneously into rabbits, it causes a fall of blood sugar. It is also active if given by mouth. Pepsin does not affect the hypoglycemic action. By treating an extract with pepsin and hydrochloric acid, the action of 'secretin' which stimulates the external secretion of the pancreas, is abolished but the action of 'duodenin' on the internal secretion of insulin remains unchanged. Trypsin seems to reduce the activity of duodenin—H HELLER *Arch Exptl Path Pharmacol*, 177 (1935) 127 through *Quart J Pharm Pharmacol*, 8 (1935) 153

ANALYTICAL

Acetone, *n*-Butanol and Ethanol—Analysis of, in Aqueous Solution Ten cc of distillate containing not more than 5 Gm of alcohols is diluted to 100 cc and 10 cc of this dilution is added to a cold mixture of 10 cc of 0.4*N* potassium dichromate and 10 cc concentrated sulphuric acid in a 2.5 by 25 cm test-tube. Two glass rods are dropped into the tube and the contents are thoroughly mixed. A stopper carrying a 1-mm capillary tube, the lower end of which is bent at right angles, is inserted and the tube placed in a vigorously boiling water bath. After 10 minutes it is cooled and diluted to 400 cc in a 1 liter Erlenmeyer flask. Fifteen cc of a 20% potassium iodide solution is then added, the flask is stoppered and allowed to stand 2 minutes, and the iodine released is titrated with 0.1*N* thiosulphate. A blank is run in the same way. The difference is designated as M_1 and has a value as shown by the equation

$$M_1 = 6.92B + 0.691A + 8.78E$$

in which M_1 is in cc of dichromate consumed, B is equal to the weight, in grams, of butanol, A the acetone and E the ethanol. A second titration is made to obtain another equation, and one of two procedures may be used. In one, a second oxidation, exactly like the above, is applied to a sample of distillate extracted with carbon tetrachloride. Twenty cc of the distillate is placed in a test tube with 40 cc of carbon tetrachloride, shaken, and allowed to stand 2 hours at 25° C. Ten cc of the aqueous solution is removed, diluted to 100 cc and 10 cc of this solution oxidized as above to obtain a value, M_2 which is given by the equation

$$M_2 = 2.75B + 0.386A + 8.22E \text{ plus correction}$$

Instead of extracting with carbon tetrachloride another equation may be obtained by carrying out the oxidation under different conditions. Ten cc of original distillate, containing not more than 2 Gm of alcohols per 100 cc, is diluted to 100 cc, and 5 cc of this dilution is added to a cold mixture of 25 cc of concentrated sulphuric acid and 10 cc of 0.4*N* potassium dichromate and the procedure for M_1 followed. A blank is run in the same way. The difference in titration is multiplied by two to give the value, N, shown in the equation

$$N = 24.62B + 17.68A + 8.84E$$

Then from the three equations the butanol, acetone and alcohol values may be calculated.—L. M. CHRISTENSEN and E. I. FULMER *Ind Eng Chem, Anal Edit*, 7 (1935), 180 (E. G. V.)

Acetylsalicylates—Decomposition of Acetylsalicylic drug mixtures kept in paper containers decompose on storing. Total salicylic acid was determined by hydrolyzing with alkali and determining the salicylic acid formed by bromometry according to Koppeschaar. The content of the preparations in free salicylic acid (*s e*, formed due to decomposition) was determined similarly without the previous saponification. As even pure acetylsalicylic acid decomposes under this treatment to some degree the value obtained for free salicylic acid should be diminished by 6.48%. Freshly made Kalmopyrine contained practically no free salicylic acid, a sample 6 months old contained about 12% and a sample stored for 2 years contained 44%.—V. GERVAY *Magyar Gyagyszereszlud Tarsasag Ertesuloje*, 11 (1935), 241, through *Chem Abstr*, 29 (1935), 3776

Acid Indices of Official Oils and Waxes Lime Liniment of the Belgian Pharmacopoeia IV. The variations in the different methods for determining the acidity of fats and waxes recommended in the Belg. Phar. IV are pointed out and tabulated. The following changes in the paragraph relative to the technique used to determine the acid index are recommended. Dissolve 2 Gm of the substance in 20 cc of a mixture of equal volumes of neutral ether and chloroform add 5 drops of phenolphthalein, titrate with a 0.1*N* solution of alcohol potassium hydroxide to the appearance of a red color persisting for 15 seconds. The acid index is equal to the number of mg of potassium hydroxide used to neutralize the free acid of 1 Gm of the substance analyzed (1 cc of 0.1*N* KOH is equivalent to an acid index of 2.8056). Acid indices for the individual fats and waxes are recommended and since linseed oil is used in the preparation of lime liniment, the following change is urged. The acid index of linseed oil should be less than 2.2 (equivalent to 0.8 cc of 0.1*N* alcoholic KOH).—GARY P. WEIL and CLAIRE ANSELME *J. pharm. Belg* 17 (1935) 377-381, 399-401 (S. W. G.)

Alcohol—Determination of, in Tinctures A comparison of different methods of determination of alcohol in tinctures showed that sufficient accuracy could be obtained by the methods of the British, Swedish or German Pharmacopœias, the two latter being the simpler and more convenient. The British method is more troublesome and requires to be checked by a determination of the refractive index of the distillate. The British method (modification II) is very suitable for the determination of alcohol in tinctures containing ether.—A JERMSTAD and O ØSTBY *Norsk Farm Tidsskr*, 43 (1935), 4, through *Quart J Pharm Pharmacol*, 8 (1935), 122 (S W G)

Alkaloidal Salts—Estimation of, by Direct Titration of Their Acid Radicles The author describes a method which he has used since 1927 as a control method in the preparation of compressed and hypodermic tablets. The distinguishing characteristic of his method is the use of benzyl alcohol as the solvent instead of alcohol water solvents. A table showing some typical results would indicate that the method is quite satisfactory for the purpose intended.—FELICE A ROTONDARO *Am J Pharm*, 107 (1935), 237 (R R F)

Alkaloids—Determination of Application of the Mercurimetric Method to New Alkaloid Products The mercurimetric method was successfully applied to determination of these alkaloids. They were precipitated from a 1% solution by the use of the Mayer-Valzer reagent (mercuric iodide alkaloid hydroiodide) and the complex destroyed by a mixture of nitric and sulphuric acids. The mercuric ion was precipitated by nitroprussiate and titrated with 0.1N sodium chloride. Tables of actual and theoretical equivalents are given. Apioi was detected by the following method also. To a mixture of 1 cc of a 1% aqueous alcohol solution of the alkaloid and 5 drops of a 2.5% aqueous alcoholic phosphomolybdic acid solution was added 0.5 cc concentrated sulphuric acid ($d = 1.84$), the mixture stoppered and shaken well. The color became an intense greenish blue changing to red orange on heating 2-3 minutes but returning to blue when cooled. Addition of 2-3 drops of 12% hydrogen dioxide before heating produced a yellow color which after heating changed to a persistent beige. The reaction is sensitive to 1 mg.—A IONESCO-MATIU and C POPESCU *Bull soc chim biol*, 17 (1935), 671, through *Squabb Abstr Bull*, 8 (1935), A-745

Alouin—Examination of Three Samples Solubility tests were conducted on three samples of alouin, by saturating with excess solvent and macerating for forty eight hours with frequent shaking. These tests were done at ordinary laboratory temperatures, but under identical conditions in each case. A table is given which shows the results of these tests.—D B DOTT *Pharm J*, 134 (1935), 648 (W B B)

Alpha-Amylase—Determination of In order to calculate the concentration of alpha-amylase in a given enzyme preparation from the amount of starch liquefied under the specified conditions, the authors have introduced a new enzyme unit the "liquefon," defined as 'that amount of starch liquefying enzyme which will convert the standard starch paste at the rate of 25 mg of dry starch per minute at zero time under the given experimental conditions.' Since the rate at zero time is directly proportional to enzyme concentration, the number of liquefons per gram of preparation is an exact measure of the alpha amylase content. The actual procedure follows. The 150 Gm sample of starch paste is cooled to about 19.5° C, so that after stirring in the enzyme infusion or the sodium chloride solution the temperature of the stirred paste is 21° ± 0.2° C. The correct time of stirring for the initial outflow is determined by running one or more blanks. Using this correct time, 15 cc of enzyme infusion is stirred into 150 Gm of paste and the mixture is placed in the bath at 21° C. After 59 minutes the mixture is sucked into the pipette and its outflow time is determined. The measurement of the outflow time of the mixture is begun just before the end of the hour reaction period in order to correct for the liquefaction occurring during the measurement. In order to check the stability of the paste, another blank should be run on 150 Gm of paste which has stood for 1 or 2 hours at 21° C. The outflow time of this check blank should not deviate more than 3 or 4% from the first blank. In pipetting the 15 cc portions it is necessary to avoid the introduction of saliva. A small cotton plug prevents contamination. From the outflow time of a given mixture the percentage decline is calculated, and from this the amount of starch liquefied is obtained from the table or equation. The enzyme content or activity of the infusion is derived from the amount of liquefied starch by means of the equation

$$\text{Log}_{10} L = (S - 1078) (0.000565)$$

where L = liquefons per 10 cc of infusion and S = milligrams of starch liquefied in 1 hour. From

the concentration of the infusion the number of liquefactions per Gm of preparation is calculated — S JOZSA and W R JOHNSTON *Ind Eng Chem, Anal Edit*, 7 (1935), 143 (E G V)

Aluminum—Sensitive Reagent for Separation of Aluminum and Beryllium The aluminum ion is precipitated in hydroalcoholic solution by ferrocyanides. The following reagent is recommended. Calcium ferrocyanide $12\text{H}_2\text{O}$ 20 Gm, distilled water 670 cc, alcohol (96%) 400 cc. Dissolve the ferrocyanide in the water, add the alcohol, shake, allow to stand and filter if necessary. Keep the reagent in a dark place. The sensitivity is 0.02 mg aluminum per cc. The reaction is carried out by adding the sample to the reagent and heating to boiling for several seconds, the reaction goes better if the sample contains about 0.001 Gm aluminum per cc. The same reaction may be used for quantitative determinations by nephelometry, potentiometry, gravimetric method (drying at $85-90^\circ$) and by determination of the excess of a known quantity of the reagent used, which may be done by manganometry using $N/10$ or $N/20$ solution, and in this case the sample should be in the form of the sulphate and the alcohol should be removed from the reagent by evaporation on a water-bath. The precipitate given by beryllium is more soluble than that given by aluminum and it may be separated by dilution and filtration, when the aluminum will remain as the precipitate — T GASPAR and Y ARNAL *Ann chim anal chim appl* (Mar 15, 1935) through *J pharm Belg*, 17 (1935), 510 (S W G)

Ammonia and Amide Nitrogen—Determination of, in Plant Tissue The ammonia present in plant tissues as ammonium ions, that is the free or preformed ammonia, has been determined since 1850 by distillation with magnesium oxide, preferably *in vacuo*. A study of the possibilities of interference from a number of commonly found plant constituents and of the conditions under which this determination is usually conducted, has led to the suggestion of a technique that depends upon the distillation *in vacuo* with a borax sodium hydroxide mixture used in conjunction with a phosphate buffer solution. The ammonia is then nesslerized and determined in a Pulfrich spectrophotometer. Under these conditions, interference from other substances is minimal. The new reagent is particularly designed for determinations of ammonia in solutions to which phosphate buffers have been added, as the use of magnesium oxide is then inadmissible, its convenience however, suggests that it may be generally applied with advantage — G W PUCHER, H B VICKERY and C S LEAVENWORTH *Ind Eng Chem, Anal Edit*, 7 (1935) 152 (E G V)

Antipyrine—Contribution to the microchemistry of Antipyrine sublimes with difficulty. If the sublimation is continued over an extended period of time crystals suggesting snow crystals are obtained. The reaction is not definite for quantities less than 1 mg. Antipyrine may be beautifully crystallized by taking up in water and adding very fine crystals of sodium chloride. This "salting out" process results in the formation of many prismatic crystals, right angled, six angled plates with an upper angle of 128° and side angles of 116° and oblong diamond shaped crystals with an acute angle of 66° . If nitric acid is added to a small quantity of antipyrine a beautiful color results which, however, disappears upon evaporation of the acid. When the acid is completely evaporated white crystals result which polarize light with a brilliant play of colors. The reaction is not very sensitive, 2 mg being required for positive reaction. If antipyrine is first salted out and then a drop of sodium nitrite solution and a drop of hydrochloric acid are added, sea green crystals are obtained. This reaction is one of the best for antipyrine and has a sensitivity limit of 0.1 mg and a dilution limit of 1:300. Potassium ferrocyanide followed by sulphuric acid results in star formations. In several places thin diamond-shaped crystals may be seen which have an acute angle of 82° (Limit 0.1 mg dilution 1:200). Potassium ferricyanide also gives beautiful crystals especially if the antipyrine is precipitated from diluted hydrochloric acid solution with the ferricyanide and a drop of acetone added just previous to the precipitation. Needles grouped in star formations are found (Limit $\frac{1}{4}$ mg dilution 1:200). Sodium nitroprusside gives excellent crystallization in acid solution (Sensitivity limit 0.1 mg dilution 1:200). Platinum chloride gives yellowish crystals with acid solutions of antipyrine (Limit $\frac{1}{4}$ mg dilution 1:200). If sodium iodide is added to the crystals obtained with platinum chloride a black mass of fine crystals is immediately formed. This soon changes to dark red with the formation of feather crystals — M WAGENAAR *Pharm Weekblad*, 72 (1935) 642 (E H W)

Arsenates—Volumetric Determination of The conditions necessary for the volumetric determination of arsenates by means of their reduction to arsenites by potassium iodide in the presence of sulphuric acid and titration of the arsenite formed by iodine in alkaline solution were

studied The three factors considered were the quantity of sulphuric acid and potassium iodide used and the duration of heating Correct results are obtained when the molarity of the arsenate solution, expressed in terms of arsenic pentoxide, lies between 0.0165 and 0.00099, if 2 cc. of sulphuric acid ($d = 1.8$) and 0.8 Gm. of potassium iodide are used for each 10 cc. of arsenical solution and if the duration of heating on the boiling water bath is about 10 minutes —M. F. TABOURI and H. AUDIER *Bull. soc. chim. mem.*, 1 (1934), 1570, through *Squibb Abstr. Bull.*, 8 (1935), A-748

Arsenic—Quantitative Determination of Small Amounts of An exhaustive investigation of the methods proposed for this determination is discussed and the following conclusions offered (1) The methods for the quantitative determination of the arsenic content in a preparation of fairly well known composition and that in a natural product are fundamentally different If no interferences are expected a simple oxidation titration method is satisfactory (2) The reduction to metallic arsenic by hypophosphite in strong hydrochloric acid solution is improved for this work (3) The methods which depend upon the isolation of the arsenic by means of the Schneider distillation procedure are not applicable because in these microchemical technique has not been sufficiently developed (4) For the quantitative determination of arsenic in a natural product the arsenic mirror formation or reduction by hypophosphite are methods that might be recommended In the reduction to arsine the use of zinc powder is preferred to granular zinc Any arsine remaining dissolved in the evolution flask is driven out simultaneously by a stream of hydrogen The arsenic mirror is dissolved in iodine monochloride solution and the separated iodine is determined volumetrically in strong hydrochloric acid solution in the presence of cyanogen with iodate Marsh's technique for the mirror formation is improved —J. GANGL *Pharm. Monatsh.*, 16 (1935), 87-92 (H. M. B.)

Arsenobenzenes—Chemical Examination of Arsenic was determined according to Schulek and Vilecz Schulek recently proposed use of two drops of 0.5% α -naphthoflavone as indicator in micro-determinations Samples of Revival and nearsphenamine contained 18.32-19.63% arsenic, 9.40-10.42% sulphur and 6.64-7.65% sulphur distillable with hydrochloric acid Solusalvarsan samples contained 1.883-1.917% arsenic Total sulphur content was determined according to Winkler after decomposition by nitric acid and hydrogen dioxide Sulphur distillable with hydrochloric acid was determined by method of Schulek and Dozsa —S. LASZLO *Magyar Gyógyszereszlud Tarsasag Értesítője*, 11 (1935), 266, through *Chem. Abstr.* 29 (1935), 3776

Benzene—Detection of, in Alcohol If the alcohol contains much above 0.01% benzene by volume it is diluted to approximately that value with alcohol free from benzene A 40 cc. portion is placed in a 100 cc. glass stoppered cylinder with 6 cc. of carbon tetrachloride Distilled water is added to the 90-cc. mark followed by 10 cc. of sodium sulphate solution (10 Gm. anhydrous salt to 100 cc. solution) The cylinder is stoppered, shaken and allowed to stand until the layers separate Five cc. of the bottom layer is transferred by pipette to a test-tube Three cc. of nitrating acid (containing 70 Gm. of 20% oleum, 45 Gm. concentrated sulphuric acid and 43 Gm. of concentrated nitric acid) is measured in a small cylinder and added to the test-tube shaking During 10 minutes the tube is shaken twice more, and at the end of that time 20 cc. of distilled water is added rapidly from a cylinder After mixing by pouring into another test tube and back again the bulk of the water layer is decanted and discarded The lower layer is placed in an evaporating dish on an electric hot plate When the carbon tetrachloride is gone, the dish is emptied into the test tube just used, and is rinsed into this tube with 1 cc. of amyl alcohol The dish is then rinsed into the tube using 4 cc. of caustic soda solution (140 Gm. made up to 250-cc. solution) The tube is mixed by swirling and then 1 cc. of acetone is added, the tube swirled again and placed in a rack for observation of color produced in the top layer Pure benzene at the concentration of 1 in 10,000 by volume in rectified alcohol gives by this test a red color with a purple quality in the top layer This color holds for some hours and then fades to a dull orange red As the benzene content rises above 0.01%, the color produced soon becomes too dark for identification Pure toluene gives a slightly brownish yellow and reagent xylene produces a definite though not intense green which fades in 30 minutes, giving way to a dull orange Blanks should be run —A. C. LANSING *Ind. Eng. Chem., Anal. Edn.* 7 (1935), 184 (E. G. V.)

Calcium and Phosphorus Analysis—Digesting Biological Materials for Weighed samples of suitable size are placed in 500-cc. Kjeldahl flasks, 20 to 30 cc. of concentrated nitric acid is added and the flasks are then heated gently, with frequent stirring until the samples pass into a semi colloidal dispersion Heating to dryness must be avoided The heating should require about 30

to 45 minutes. Ten cc of 70% perchloric acid is added and the flask placed over a free flame. Very low flames are necessary during the perchloric oxidation. When fuming begins the flame is so adjusted that only a trace of perchloric acid fumes reach the upper region of the flask. The heating is continued until the solution is colorless or only a faint yellow color remains. After slight cooling 50 cc of distilled water is added. Vigorous boiling occurs driving out the remainder of the nitrogen dioxide fumes leaving a clear solution. The solution is filtered into a volumetric flask and the Kjeldahl is thoroughly washed. When the solution has cooled it is made to volume and aliquots are taken. Calcium and phosphorus may be determined by the usual procedures.—H W GERRITZ *Ind Eng Chem, Anal Edit*, 7 (1935), 167 (E G V)

Calcium Hydroxide—Solubility and Determination of Calcium hydroxide, obtained by slaking quicklime, comes into equilibrium with water after shaking for one hour and is much more soluble than the crystalline variety, at 15° C, the solubility of the former is 0.133% and of the latter 0.122%, calculated as calcium oxide. The determination of calcium by weighing as oxide after precipitation as oxalate is subject to several sources of error, and should be discarded, accurate results may be obtained by the volumetric method using permanganate provided that the precipitated calcium oxalate is washed, before decomposition with acid with a saturated solution of calcium oxalate in water. The author recommends the use of pure precipitated calcium carbonate as a volumetric standard, a weighed quantity of the carbonate being ignited to oxide in platinum, slaked and titrated with acid using methyl orange or methyl red as indicator.—H BASSETT *J Chem Soc Lond* (1934), 1270, through *Quart J Pharm Pharmacol*, 8 (1935), 117 (S W G)

Camphor—Titrimetric Determination of, in Drug Preparations To substance equivalent to 0.2 Gm camphor (or hexetone) in a 100-cc flask add 0.15 Gm sodium bicarbonate, a drop of 0.1% bromophenol blue and 10 cc hydroxylamine hydrochloride (2 Gm dissolved in 10 cc water and 50 cc absolute alcohol). Heat the mixture with small flame for four hours under a short reflux condenser. Cool, and add 10% hydrochloric acid until the blue color changes to yellow. Prepare a blank in the same way and to each add carbon dioxide free 0.1N sodium hydroxide until a green color appears. Then add solid phenolphthalein to each solution and further titrate until a lilac color is shown by both liquids. The difference in no. of cc required is equivalent to camphor content, each cc of 0.1N sodium hydroxide is equivalent to 0.0152 Gm camphor.—R WOLSTADT *Magyar Gyógyszerészeti Társaság Értesítője* 11 (1935), 257, through *Chem Abstr*, 29 (1935), 3776

Cellophane and Kuprophane as Dialysis Membranes Cellophane No 300 (Kalle and Co) has a thickness of 20 μ and Kuprophane (Bemberg A G) 10 μ . If the permeability of Kuprophane is 100 then cellophane is 51, and the parchment paper used for dialysis is 13. The membranes have sufficient strength when wet, and are satisfactory for rapid electrodialysis.—H BRINTZINGER and H OSSWALD *Kolloid Ztschr*, 70 (1935), 198, through *Pharm Zentralh*, 76 (1935), 277 (E V S)

Chloride and Potassium Ions—Volumetric Microdeterminations of The chloride determination follows. Samples of the order of 1 cc of 0.01N solution are titrated directly with 0.005N silver nitrate solution, using a 10-cc burette calibrated in 0.02-cc divisions. The samples are conveniently contained in the cut-off end of a test-tube. The conditions for a satisfactory end point with dichlorofluorescein are approximately neutral solution, not over 2 drops of 0.01% solution of indicator, acetone added in small amounts approximating the original volume of the sample and illumination from the side or rear of the observer. For the determination of potassium excess of chloroplatinic acid solution is added to the sample and the solution is evaporated to dryness over a water-bath. The residue is washed with successive portions of 80% alcohol and 20% ammonium chloride both saturated with potassium chloroplatinate. The precipitate is washed into a crucible with 1 cc hot water. The potassium chloroplatinate is reduced to chloride and platinum in neutral solution with finely divided magnesium. The chloride set free is then titrated as described above.—B BULLOCK and P L KIRK *Ind Eng Chem, Anal Edit* 7 (1935), 178 (E G V)

Chloroform and Carbon Tetrachloride—Reaction for Distinguishing between Papaverine hydrochloride is soluble in chloroform but insoluble in carbon tetrachloride. Ten mg of papaverine hydrochloride (or any other alkaloid having this property) is added to one cc of the liquid (CHCl₃ or CCl₄) in which a small fragment of iodine has previously been dissolved. If the liquid is chloroform the violet color will change to yellow or yellowish red, if it is carbon tetrachloride the

violet color will remain unchanged and the alkaloidal salt will not go into solution This reaction is suggested as a check to be used with other means of differentiation between these two liquids, e g, refractive index, etc —J ROZEBOOM *Pharm Weekblad*, 72 (1935), 689 (E H W)

Chromatographic Adsorption and Its Applications The method of separation by chromatographic adsorption, devised by the botanist Tswett, consists in passing a solution of the colored substances to be studied through a tower of finely powdered adsorbing material, the various pigments are adsorbed at different levels, and can be isolated and studied separately The method is described in detail, and various applications which have been made to date are reviewed Forty-one references —EDGAR LEDERER *Chimie & Industrie*, 33 (1935), 1072-1078 (A P C)

Cod Liver Oil—Vitamin Potency and Associated Characteristics of Average In order to determine the average quality of cod liver oil purchased in the retail market, 67 samples were obtained from various sources and sections of the British Isles The blue value, vitamin A and vitamin D values were determined The determinations were all made by approved methods The oils were divided into 5 groups according to localities and average blue values for each group determined Composite oils were prepared from 64 of the samples, a composite of samples below the median, one from those above the median, and one from a mixture of the latter two Blue values were determined directly in all cases and on the unsaponifiable portion in 36 cases Spectrophotometric examinations of 3 of the composite samples were also made The vitamin A and D values were determined on the composite samples A number of tables of results are given and the possible errors introduced by the methods used and also by the 'personal equation' are discussed The following conclusions are drawn by the authors The characteristics of average cod liver oil as obtained above are Blue value 9.3, blue value (unsaponifiable matter) 21.8, E 1.1% 328 μ 0.505, vitamin A (biological assay) 670.0 units per Gm, vitamin D (biological assay) 81.0 units per Gm The vitamin assays were based upon results from 40 pairs of rats for each assay It is calculated that the error in the vitamin A assay does not exceed -14 to +17% and that from the vitamin D assay -14 to +16% by a 22/1 chance —RONALD S MORGAN and HARRY PRITCHARD *Analyst* 60 (1935), 355-368 (A H C)

Copper—Determination of, in Foods with Special Reference to Milk A method for determining copper in foods is given in detail The original paper should be consulted for details Part of the authors' summary follows 1 Diphenylthiocarbazon in chloroform is used as an extraction agent to remove copper from foods 2 With milk containing 0.12 parts per million reliable duplicates may be obtained using as little as 20 Gm of milk The error is ± 0.02 parts per million 3 The method is applicable to foods in general and is unaffected by such metals as iron, tin, aluminum, lead, zinc, nickel and manganese 4 After all possible precautions to avoid contamination the copper content of sixteen samples of milk from cows of different breeds and different localities was found to range from 0.09 to 0.17 and a mean of 0.12 parts per million —N D SYLVESTER and L H LAMPITT *Analyst*, 60 (1935), 376-382 (A H C)

Coriander (*Coriandrum Sativum*)—Report on Examination of Samples of Indian and Foreign Different samples of Russian coriander contained approximately the same amounts (average 22.18%) of material soluble in petroleum ether, Moroccan, Tuticorin and local (Udamalpet) varieties were similar in their contents of ether extractives (average 20.11%) In fresh samples of all varieties the free fat acids amounted to 4.3-8.1 mg potassium hydroxide per Gm of oil, samples showing free fat acid values of 19.5 were definitely characterized as old stock The free fat acid values of the ether extractives of coriander constitute a valuable index of the quality and age of the product *New Method for Determining the Essential Oil Content of Coriander*—Extract 50 Gm of very finely powdered sample successively with 120 cc and 60 cc of 96% alcohol in two stages of 6 hours each at water-bath temperature, using a double-surface condenser Decant the first extract and press out the second extract as thoroughly as possible with a fine muslin cloth Dilute the combined extracts to 280 cc with distilled water and steam distil until the distillate is no longer cloudy Saturate the distillate with sodium chloride and extract with small amounts of petroleum ether Dehydrate the combined extracts with anhydrous sodium sulphate and filter into a flask containing a known amount of previously dried coconut oil Wash the sodium sulphate residue and the filter paper several times with anhydrous ether to remove traces of essential oils Remove the greater portion of the ether by means of a Soxhlet apparatus in a water-bath maintained at 45° and complete the removal of ether by drying *in vacuo* until the loss in weight is approximately 2 mg per 0.5 hour under 660 mm pressure The weight which is highest

in the series after attaining this steady loss in weight represents the combined weights of the essential oil, coconut oil and the flask. The method gives concordant results in duplicate determinations. The coconut oil prevents the volatilization of the essential oil during the removal of the ether. The oven-dry samples of Russian coriander contained approximately twice as much essential oil as the others.—B. VISWANATH and C. V. RAMASWAMI, *Ayyar Agr Lwe stock India*, 4 (1934), 583, through *Chem Abstr*, 29 (1935), 4130

Creatine and Creatinine—Microchemical Identification of The following methods for the differentiation of creatine and creatinine are given: 1. Crystallization of the sample from a drop of water on a slide and observation of the types of crystals formed. 2. Observation of crystals formed on addition of a drop of a saturated solution of picric acid or a drop of a solution containing 6 Gm. iodine and 8 Gm. potassium iodide in 150 cc. instead of the drop of water in 1. The crystals are described and those from the first two procedures are illustrated. 3. Dissolve about 1 mg. of the product in 1 drop of ammonia in a porcelain dish and add 1 drop of a saturated solution of picric acid. If the product contains creatinine, a persistent orange color develops, whereas with creatine the color of the mixture is the same as a control of ammonia and picric acid. If an orange tint which becomes stronger at first and then changes to yellow is observed, creatinine is present, the alkaline medium causing it to change to creatine. 4. Using a 1% solution of sodium nitroprusside instead of picric acid, a blood red color is obtained with creatinine and a faint rose color with creatine.—GEORGES DENIGES, *Bull. soc. pharm. Bordeaux*, 73 (1935), 89-97 (S. W. G.)

Duododithymol—Assay of The tests and assay of duododithymol are critically reviewed. The following conclusions are drawn: The Belg. Phar. IV should retain the following points: 1. Modification of the formula for duododithymol according to Bougault (*J. pharm. chim.*, 17 (1918), 221). 2. Color: Yellowish red powder with a characteristic aromatic odor. 3. Solubility: Insoluble in water and glycerin, slightly soluble in alcohol, almost completely soluble in ether, more soluble in chloroform, very soluble in benzene, test-limit of solubility in benzene (20 p). 4. Test of neutrality: Aqueous filtrate neutral to litmus. 5. Moisture: 1 Gm. placed in a sulphuric acid desiccator for 24 hours loses at the maximum 0.01 Gm. 6. Mineral matter: Calcination with sulphuric acid, maximum of 3.5% of ash as sulphates. 7. Determination of mineral halides: Assay limit with solution of silver nitrate, after exhaustion in the cold, maximum 1% evaluated as potassium iodide. 8. Determination of organic chlorine: Calcination with potassium hydroxide or carbonate and determination of the chlorine in the residue. 9. Free iodine: Assay limit with N/10 hyposulphite, maximum 0.25% iodine. 10. Iodate + free iodine: Assay limit with N/10 hyposulphite, maximum 0.50% iodine. 11. Determination of iodine: Technique, minimum 44% of the dried product.—LEON LECLERCQ, *J. pharm. Belg.*, 17 (1935), 423-428, 449-453, 467-471 (S. W. G.)

Essential Oil Content of Drugs—Improved Method for Estimation of A detailed method for the estimation of essential oil content of drugs including a description of the method of operation of the apparatus, the condition of the sample before testing and the details of the distillation is given. A table is included which shows the amount of essential oil yielded by a number of samples of drugs, herbs and spices.—T. TUSTING COCKING and G. MIDDLETON, *Perf. and Ess. Oil Rec.*, 26 (1935), 207 (A. C. DeD.)

Halides—Volumetric Determinations of Use of Dichlorofluorescein as an Adsorption Indicator. Dichlorofluorescein has been used as an adsorption indicator in the argentometric titration of organic hydrochlorides dissolved in alcohol and inorganic halides in alcohol or aqueous solution. The analytical results have been within experimental error of the theoretical values on pure chemicals or of values obtained by the standard Volhard procedure on chemicals of ordinary commercial purity.—K. BAMBACH and T. H. RIDER, *Ind. Eng. Chem., Anal. Ed.*, 7 (1935), 165 (E. G. V.)

Hexamethylenetetramine—Determination of, and Its Decomposition in Dilute Aqueous Solutions Re-examination of the method previously described shows that the micromethod without distillation is practically reliable especially for rapid determinations of hexamethylenetetramine in sugar containing drug mixtures. The distillation method naturally gives more exact values. Dilute solutions of hexamethylenetetramine may easily be decomposed during storage.—E. SCHULEK and V. GERVAY, *Magyar Gyógyszerészeti Társaság Értesítője*, 11 (1935), 272 through *Chem. Abstr.*, 29 (1935), 3776

Insulin, Commercial—Rapid Method for the Determination of Purity of, in Vitro An acidified 0.2% solution of potassium ferrocyanide is a specific reagent for the precipitation of insulin from solutions. Several indifferent substances may then be precipitated from the insulin-free solution with picric acid. The authors have found that many chemical determinations depending on this principle may be made. These chemical determinations are useful and comparable with the physiological determinations.—I. I. NITZESCU and ST. SECAREANU *Bull. soc. chim. biol.*, 17 (1935), 118, through *Pharm. Weekblad*, 72 (1935), 696 (E. H. W.)

Iodine—Stability of Solutions of A study of the stability of solutions of iodine in various solvents. *Methyl Alcohol*—A solution of iodine in pure methyl alcohol showed only a very slight change in the analytical figures after keeping 160 days in a brown corked bottle, in the commercial pure alcohol some decomposition occurred. In both cases the odor of the solution showed the formation of iodoform, due to impurities in the solvent. Methyl alcohol is not recommended as a solvent for iodine. *n-Propyl Alcohol*—A 5% solution of iodine in *n*-propyl alcohol showed a considerable loss of iodine on keeping. When potassium iodide was also present the amount of decomposition was reduced, but was still considerable. *Glycerin*—A solution of iodine in glycerin showed no apparent change after keeping for one year. This also applies to a similar solution containing phenol. *Benzene*—A solution of iodine in benzene was found to have lost nearly all of its iodine after keeping for one year. Petroleum ether is to be preferred, the losses being much smaller. *Liquid Paraffin*—With pure liquid paraffin the strength dropped to about two thirds after a few days, and then remained constant. With a less pure oil the amount of free iodine dropped continuously. *Ether*—A solution of iodine in ether showed no change in strength after six months. *Chloroform*—A chloroform solution dropped, immediately after making, from 2.9% to 2.5%, and then remained constant in strength for six months. *Carbon Tetrachloride*—This solution is stable for at least six months. *Acetone*—In solution of acetone iodine forms iodoacetone which has been used as a poison gas. The strength rapidly drops and then remains constant. *Water*—Aqueous solutions, containing potassium iodide, are stable if kept in well-closed stoppered bottles, but not in corked bottles. *Tinctura Iodi Decolorata*—This is a very complex product which when first prepared contains ammonium iodide and diiodoamine. It decomposes rapidly, and should be eliminated from the Pharmacopœias.—W. HÖR. *Svensk Farm. Tid.*, 38 (1934), 422, 437, 457, 477, through *Quart. J. Pharm. Pharmacol.*, 8 (1935), 125 (S. W. G.)

Lactometer—New Type, Reading Total Solids The new lactometer herein described has a scale that reads directly in terms of percentage of total solids. The scale reading is predicated upon a butter fat content of 4% and is subject to a correction amounting to 1.2% of total solids for each variation of 1% of butter fat in the milk. Throughout its scale length the new lactometer is useful without correction for variation in the temperature of the milk provided its temperature lies between 58° F and 62° F. Where samples are at any temperature between these limits, or can readily be brought to have temperatures within these limits, this total solids lactometer will effect great economy of time in routine milk analysis. If the readings upon it lie between 11.2% total solids and 12.7% total solids, the temperature of the milk may range within the wider limits of 56° F to 63° F without any necessity of correction for temperature. The use of the total solids lactometer is not intended to do away with the check by gravimetric determination of total solids in all exceptionally important cases. Its use is merely a short cut in routine work. It is an instrument deliberately made to have the sensitivity conformable to routine milk analysis of to day, and deliberately made to give directly or after simple correction the figure (for total solids) that is otherwise arrived at indirectly by calculation through the general milk equation.—DAVID W. HORN. *Am. J. Pharm.*, 107 (1935), 212 (R. R. F.)

Methyl Salicylate—Determination of, According to D. A. B. VI The directions for assay are clear and understandable, but the results obtained are not uniform. Due to the small amount (1 Gm.) of methyl salicylate used in the assay, slight errors in weighing or measurements of reagents cause a high percentage of error. The use of alcoholic alkali as the saponifying agent gives a slower reaction than an aqueous solution and makes exact measurements more difficult. An assay based on the determination of salicylic acid produced a low result (95%). The difficulties encountered in the assay may be eliminated to some extent by increasing the amount of methyl salicylate to 2.5 Gm.—R. ECKERT. *Pharm. Zentralh.* 76 (1935), 237 (E. V. S.)

Micro- and Submicro-Colorimetric Determination of Iron The author recommends the

use of hydroxyquinoline for the determination of iron in organic liquids This method is based on the solubility of the ferric derivative of hydroxyquinoline in alcohol The solution is strongly colored a dark green and absorbs blue radiations, and may be used for colorimetric determination The reaction may be used for the determination of magnesium by finding the amount of hydroxyquinoline present by means of iron, and, from the hydroxyquinoline the amount of magnesium hydroxyquinolate—M J LAVOLLAY *Bull soc chim belg*, 17 (1935), 432, through *J Pharm Belg*, 17 (1935), 533 (S W G)

Micro-Copper-Pyridine Reaction—Application of, to Some Organic Acids The author has investigated the reaction used by Zwickler for the identification of barbituric acid derivatives adapting it to some of the organic acids The reagent consists of 4 cc of (10%) copper sulphate solution 1 cc pyridine and 5 cc of water When a few crystals of salicylic acid are introduced into the reagent crystal clumps, prisms and sometimes irregular hexagons are immediately produced The crystals are greenish blue and strongly birefringent Sodium salicylate gives an amorphous precipitate which soon resolves into the above described crystals When acetyl salicylic acid is introduced into the reagent the drop remains clear Upon scratching with the platinum needle, however, crystallization takes place with the formation of purplish blue prisms, rhomboids and hexagons The crystals are dichroic Calcium acetylsalicylate gives similar crystals after scratching Benzoic acid or benzoates give birefringent, dichroic (colorless to blue) prisms which soon resolve into stellate groups Cinnamic acid (dissolved in a little ammonia) gives rosettes of blue green prisms which later form into plates Anisic acid gives oblique dichroic prisms showing birefringence (colorless to blue) The prisms finally grow into stellate groups Anthranilic acid gives elongated birefringent hexagons and disk-shaped crystals Fumaric acid gives blue crystal clumps Dr Steenhauer states that the reaction is particularly valuable in distinguishing between salicylic and acetylsalicylic acids Seven photomicrographs are given—A J STEENHAUER *Pharm Weekblad*, 72 (1935), 667 (E H W)

Microsublimation as a Pharmacopoeial Test The author comments upon the various microsublimation tests applied by the Swiss Phar V Some are practical but others are not accurate and could not be confirmed by the author Sixteen pharmacopoeial tests are considered Microsublimation is really unnecessary for pharmacopoeial purposes since chemical identification is more easily accomplished in other ways and is more convenient for the pharmacist—ROSENTHALER *Schweiz Apoth-Zig*, 73 (1935), 273 (M F W D)

Opium—Comparison of Proposed Methods The authors, constituting the Group Committee on Opium Assays of the U S P Committee on Revision criticize the opium assay procedure suggested by the International Committee Although this latter committee's method yields results which check satisfactorily, the lack of sharpness in the end point, the absence of any time saving factors, the potential hazard attending the use of smaller quantities of samples (especially in the case of gum opium), the apparent inaccuracy of the correction factor and the inconstant variations in results obtained by different collaborators combine to establish the fact that the proposed international committee's method is inferior to the method recommended by the group committee for adoption in the U S P XI—A RICHARD BLISS, JR *et al Am J Pharm*, 107 (1935), 193 (R R F)

Organic Matter in Plant Material—Destruction of, by the Use of Nitric and Perchloric Acids Place a 4-Gm sample of the material to be oxidized in a 400 cc beaker and add 10 cc of concentrated nitric acid Cover the beaker with a watch glass and heat gently until any rapid initial reactions have subsided Then heat to boiling and boil until the contents of the beaker are almost dry Remove the beaker from the hot plate and add 10 cc of dilute nitric acid (1 to 1) and 10 cc of perchloric acid (70 to 72%) Replace the cover glass and heat very gently to a low boiling temperature, avoiding superheating Maintain this temperature until all organic material has been removed from the sides of the beaker and from the solution, which will be indicated by a colorless or slightly colored solution Remove the cover glass, allow the beaker to cool a few minutes and wash any adhering salts into the beaker If the cover glass is washed with perchloric acid, the contents of the beaker need not be cooled The above method is applicable to a wide variety of plant materials, calcium, magnesium, potassium and phosphorus are determined by standard methods—J E GIESEKING H J SNIDER and C A GETZ *Ind Eng Chem, Anal Edu* 7 (1935), 185 (E G V)

Paraffin Wax—Tensile Strength and Density at Various Temperatures The tensile or

breaking strength of commercial paraffin wax was investigated at temperatures between -10° and 30° C. It varies considerably with the temperature, reaching a maximum value of 32 Kg per sq cm at about 3° C. The density was also measured over the same temperature interval, below 25° C. it varies in a linear manner with the temperature, having values of 0.909 and 0.922 Gm per cc at 25° and 5° C, respectively. There appeared to be no direct relationships between the two quantities measured.—W F SEYER and K INOUE *Ind Eng Chem*, 27 (1935), 567 (E G V)

Peppermint Oils—Detection of Japanese Mint Oil in The following test for the detection of inferior Japanese oils in oil from *Mentha Piperita* is given. The oil (0.1 cc) measured in a 1-cc pipette (graduated in 0.01 cc) is mixed in a test-tube with 5.0 cc of a 2% solution of freshly redistilled aniline in glacial acetic acid, added from a burette. The reaction mixture is examined in a 1-cm cell of a Lovibond tintometer (B D H pattern) after an interval of 10 minutes. The reaction mixture must be protected from bright light. The presence of furfuraldehyde in the Japanese oils causes a red color having a red value of 4.5 to 7.4 when determined as above. Other oils also give some red color which varies somewhat for different types of oils (French, English, Italian, American, etc.) but is very constant for each type and in all cases is much lower than the Japanese, rarely exceeding a value of 1.0. A rough quantitative estimation may be made of the extent of adulteration. Numerous tables are given showing results obtained with various types of true oils, with adulterated oils and with mixed samples of known composition. These results seem to be very satisfactory and conclusive.—D C GARRATT *Analyst*, 60 (1935), 369-376

(A H C)

Phenolphthalein—Irreversible Fading of Besides the known reversible fading of phenolphthalein, an irreversible fading has been observed and investigated. It takes place on long keeping and is important when the indicator is used as a color standard. The effect is attributed to the formation of a tertiary carbinol carbonate ion and its subsequent reaction with hydroxyl ion, since the phenomenon is not observed with phenoltetrachlorophthalein which does not form the tertiary ion.—A THIEL and G COCH *Z anorg allgem Chem*, 217 (1934), 254, through *Squibb Abstr Bull*, 8 (1935), A 666

Pyramidon—Microchemical Reactions for The author gives the following microchemical reactions for pyramidon. Pyramidon is not sublimable and identification by this method is impossible. Crystallization by precipitation is best accomplished by the process of salting out. A few grains of sodium chloride are added to an aqueous solution of the substance which causes it to crystallize in prisms often exhibiting refractive coloring longitudinally. The reaction is not particularly sensitive (0.1 mg). Mayer's reagent causes a precipitate soon resolving itself into yellowish white prisms with angles of 60° and 120° . Recrystallization from acetone improves the reaction. 0.05 mg (1/200) may be detected. Potassium cadmium iodide and potassium zinc iodide give similar reactions. With platinum chloride beautiful crystals are obtained. These are colored violet by an oxidation product of pyramidon. The reaction works well in a 1/100 solution having a minimum sensitivity of 0.1 mg. Gold chloride gives yellow needles and rosettes which are colored black upon the addition of nitric acid. (Limit 0.05 mg dilution 1/200) Picric acid gives prisms. Sensitivity 0.1 mg dilution 1/200. Para nitro phenol results in beautiful needles. (Limit 0.1 mg dilution 1/200) Iodine potassium iodide gives an excellent crystallization especially when acidified with hydrochloric, sulphuric or acetic acid. Upon the addition of a few drops of acetone two kinds of crystals may be seen, one woolly and yellowish and one prismatic. (Limit 0.02 mg dilution 1/200) Bromine potassium bromide gives green needles with an acidified 1/100 pyramidon solution. The reaction is not very sensitive. Chinosol gives green needles in stellate formation. (Limit 0.2 mg dilution 1/100) Chinosol gives no trace of crystals with antipyrine and by means of this reaction 1% of pyramidon in antipyrine may be detected. Recrystallization from acetone is not necessary in this case.—M WAGENAAR *Pharm Weekblad*, 72 (1935) 612

(E H W)

Red Pill (or Opium Substitute) The author gives in detail a method for the determination of heroin and morphine in a type of pill used for smoking purposes by addicts. Originally the pills were encountered in Shanghai but were later discovered in narcotic raids in the United States. They are very crude of variable physical and chemical constitution and the work of detecting and determining narcotic alkaloids entails a great deal of tedious analysis, mainly because only traces of heroin and morphine are present, mixed with a host of other innocuous but troublesome materials.—PETER VALAER *Am J Pharm*, 107 (1935), 199

(R R F)

Sterols—Behavior of, toward Digitonin Tests showed that only those sterols with a hydroxy group on carbon atom No 3 in the same steric position as in cholesterol, which do not have too great a variation in the side chain give precipitates with digitonin—E FERNHOLZ *Z physiol Chem*, 232 (1935), 97, through *Squibb Abstr Bull*, 8 (1935) A 598

Surgical Dressings Criticism of Some of the Codex Standards The first point which appears to merit criticism in the new Codex concerns the adopted abbreviation for gram (g) The symbol employed in the B P (G) should have been selected in order to avoid the possibility of confusion between gram and grain For the convenience and easy reference of the majority, it is suggested that the English names for surgical dressings be given predominance The difficulties of the Dressings Sub-Committee in drawing up more stringent specifications might have been alleviated by stipulating that no consignment of any dressing should be condemned on one single examination In the absence of research revealing tests other than visual inspection, to attempt to describe a dressing in circumspect phrases is unsatisfactory The importance of the use of surgical dressings in the treatment of disease and the fact that most of them are invariably in contact with open wounds warrant the most exacting limits Another omission which might be remedied in subsequent editions of the Codex is the complete absence of "Actions and Uses" in the Surgical Dressings part of the book Throughout the whole section there is nothing to guide the apprentice In the opening paragraph of Part II it is puzzling to find the Codex condoning a common and abused practice by the statement 'substances are often added to the size (or filling) in order to increase the weight' without limiting such an offense to a definite percentage basis under the dressings concerned In the subsequent paragraphs on tests for moisture, water soluble extractive, foreign matter and cotton and wool it seems advisable to augment the 'dry at 100' by the addition of the words 'to a constant weight' The absorbing tests might also be improved as it is not stated how the dressing should be manipulated during compression—J BAIN *Pharm J*, 134 (1935) 747 (W B B)

TOXICOLOGICAL CHEMISTRY

Fluorine—Importance of Fluorinated Methemoglobin in the Determination of, in Industrial Hygiene The spectral absorption curve of fluorinated methemoglobin has a very intense maximum at $\lambda = 6100 \text{ \AA}$ Methemoglobin cannot be detected in presence of oxyhemoglobin in proportions of less than 25%, but if the methemoglobin is converted into its fluorinated derivative, the sensitiveness is increased to 10% Determination of the maximum optical density ($\lambda = 6100$) of the fluorinated methemoglobin affords a satisfactory method of determining fluorine that has been added to methemoglobin, within a range of 0.1 to 3 mg, and is therefore suitable for biological and toxicological analyses for larger amounts, standard methods are satisfactory—R FABRE and MELLE S BAZILLE *14me Congres de Chimie Industrielle Paris*, Oct 21-27, 1934 5 pp (A P C)

Humors—Chlorine Content of, after Death The chlorine content (expressed as sodium chloride) was determined in various organic liquids (26 samples of whole blood, 18 of blood plasma 10 of pericardial liquid, 9 of pleural serosities 7 of peritoneal liquid, 6 of blood from the liver) of 20 corpses, the samples in all cases having been taken not later than 48 hours after death In spite of wide variations in individual results, it is concluded that the chlorine contents of the various liquids are lower in the corpses than in the living organism the differences indicating that after death chlorine diffuses from the richer humors toward the poorer In diagnosing plasmatic hypochloremia by dilution of the blood of the cadaver (diagnosis of submersion in fresh water) such a conclusion must be based on a decrease in the chlorine content that is decidedly lower than the minimum that can be observed normally—CHARLES SOUTTER *Ann Med Legale Criminol Police Sci* 15 (1935), 385-405 (A P C)

Hydrocyanic Acid—Toxicology of Hydrocyanic acid absorbed by mouth or respiration can be identified in small quantities by distillation with dichromate and sulphuric acid The most suitable medium to receive the vapors is silver nitrate in ammonia Hydrocyanic acid is never formed by putrefaction or decomposition of tissues—PLUTARCO R ORELLA *Anales de Farm Bioquim* 6 (1935) 1 (A E M)

PHARMACOGNOSY

VEGETABLE DRUGS

Cinchona—In Amani A short historical survey of cinchona in Amani, Tanganyika Territory, is given. The alkaloid content of the various barks in different years is given, 10.55% quinine (as sulphate) in Ledger bark, and 11.21% in hybrid bark, being the highest obtained at any time. The yields of bark from the various species are given and results show that *C. ledgeriana* produces considerably less than the others. The market value of the various barks is discussed, and it is shown that the hybrid commands the best price per tree, *C. ledgeriana* having the lowest value. A description of the preparation and composition of cinchona febrifuges is given.—R. R. LE G. WORSLEY *Bull Imp Inst*, 33 (1935), 14-31 (A P-C)

Colophony—East Indian In Northern Sumatra, colophony and turpentine are obtained from *Pinus Merkusii*, the production in 1933 being 790 tons and 237 tons respectively. The colophony shows an acid value of about 193, compared with a range of 145 to 185 for the American product.—*Ber Afd Handelsmuseum Kon Ver Kol Inst* (1934) 35, through *Quart J Pharm Pharmacol*, 8 (1935), 284 (S W G)

Derris—Storage of Derris root, kept in a dry and cool place and not unduly exposed to light, undergoes no loss of rotenone on storage. If powdered, it should be kept in well closed containers. The rotenone content of the samples examined was determined by the ether crystallization method.—I. W. SPOON *Ber Afd Handelsmuseum Kon Ver Kol Inst* (1935), 90, through *Quart J Pharm Pharmacol*, 8 (1935), 284 (S W G)

Diatomaceous Earth—East Indian Deposits of diatomaceous earth in the Dutch East Indies are of four types: the Californian marine type, which occurs in a very pure form, the Hanoverian fresh-water type, two abnormal fresh water types consisting of curved hollow tubes and of long needles respectively. For the technical utilization of these it is necessary to decide which types are most suitable for particular purposes. In view of the cost of shipping such bulky material, it does not appear probable that export would be profitable.—E. C. J. MOER *Ber Afd Handelsmuseum Kon Ver Kol Inst* (1934), 89, through *Quart J Pharm Pharmacol*, 8 (1935) 284 (S W G)

Euphorbia Prunifolia Jacq This herbaceous plant is common as a weed in the cotton fields of lower Egypt. The morphology and anatomy of the plant are illustrated. The analysis of the plant shows the presence of resins, a caoutchouc like substance, euphorbone and an acrid irritant vesicating principle. The plant possesses drastic purgative properties and is commonly used by the Egyptian fellahs for that purpose.—H. KAMEL and I. R. FAHMY *Rep Pharm Soc Egypt* 6 (1934), 29, through *Quart J Pharm Pharmacol*, 8 (1935), 285 (S W G)

Ispaghula—Structure and Histology of Seeds of *Plantago Ovata* Forsk. A detailed report on the anatomy and histology of the seeds is given, including descriptive illustrations. The following summary is given: 1. Ripe seeds of *Plantago ovata* are collected in the Punjab and N. W. Frontier Provinces of India. One hundred seeds weigh from 0.148 Gm to 0.195 Gm. They are "boat shaped" about 1.4 mm wide by 2.8 mm long. The dorsal surface of the majority of seeds in commercial samples is pale gray-brown with an elliptical central red-brown spot, in a smaller number in each sample the red brown spot is irregular in size and distribution or covers the whole surface. The furrow in the ventral surface represents the hilum and contains a whitish tissue of collapsed cell walls in which there are two elliptical red-brown gaps one on either side of its center which is dark in color. 2. The single seed coat consists of (a) The outer epidermis of large, colorless, mucilage cells with a cuticle, in contact with water they swell forming a mucilaginous jelly, three regions in the hemcellulosic mucilage of these cells have different staining reactions, the cells often contain starch grains, this epidermis does not extend beyond the edges of the furrow. (b) A layer of collapsed cellulose residues of about six rows of cells. (c) The inner epidermis of suberized cells with brown contents, the pigment layer, which completely invests the endosperm. 3. The cells of the endosperm have very thick cellulose walls with large simple pits. The embryo occupies almost the entire length of the seed; its cells as well as those of the endosperm, contain protein and oil. 4. When dead seeds are moistened with water, their embryos become blackened. 5. The variation in color of the seeds is due to the inclusion of a film of air in a split of varying extent in the collapsed layer of the testa, in India the splitting occurs naturally owing to changes in the humidity of the atmosphere. Seeds grown in England remain permanently brown.

The outer epidermis of the testa is easily separated from the remainder of the seed and constitutes Ispaghula Husks " 6 The mountants which render the cellular structures most clearly evident are aniline and clove oil —E W SKYRME *Quart J Pharm Pharmacol*, 8 (1935) 161-185 (S W G)

Opium—Jugoslavian A comparison of the work of several investigators shows that opium from this country has an average of 14.5% morphine and surpasses in content that obtained from India (8%), Egypt (9.3%) Russia (9.7%) Persia (10%) and Turkey (12%) A table of comparison of this drug from 84 Turkish sources and 105 Jugoslavian sources shows that one fourth of the Turkish samples have a morphine content of less than 10% and 86.7% of the samples had a content of 14% or less, only 15% of the Jugoslavian samples showed a content of less than 14% and 75.4% of the number had a content of 15-20% Adulterants were found to be acacia, starch, toasted bread, apricot and quince kernels The production in this country varies from 20,000-200,000 Kg annually —S BECKER *Pharm Monatsh*, 16 (1935), 85-86 (H M B)

Orobanche Ramosa, L This parasitic herbaceous plant is known in Egypt as 'Haluk' The morphology and anatomy of the plant are illustrated It contains about 3% of mannite, a small quantity of sugars and tannins, traces of the glycoside orobanchin and its decomposition products, and high proportions of proteins, carbohydrates and ash The laxative properties for which this plant is used may be due to the mannite present —M A H MAHDI and I R FAHMY *Rep Pharm Soc Egypt*, 6 (1934), 35, through *Quart J Pharm Pharmacol*, 8 (1935), 286 (S W G)

Pharmacognosy Syllabuses—British and American, Compared The American pharmacognosy syllabus is considerably wider in scope than that of Great Britain and aims 'to include every crude vegetable or animal drug that the pharmacist is likely to be called upon to sell or dispense' Most of the drugs in the British Syllabuses are included in the American lists, exceptions being *Cera Flava*, *Creta Coca Mel* and *Sabina* The American syllabus embraces 305 drugs (151 primary and 154 secondary) while the British lists only 80 —G E TREASE *Pharm J*, 134 (1935) 680 (W B B)

Withania Obtusifolia, V Tack and W Somnifera, Dunal These two solanaceous species grow in Egypt The first has been recently discovered by Tackholm They closely resemble each other anatomically but have characteristic morphological differences Both of them appear to contain no solanaceous alkaloid —D Y HADDAD and I R FAHMY *Rep Pharm Soc Egypt*, 6 (1934) 41, through *Quart J Pharm Pharmacol* 8 (1935) 286 (S W G)

PHARMACY

GALENICAL

Alcohol—Concentration of, when Stored in Wooden Vessels The author stored 60 liters of 56% alcohol in a wooden barrel in a dry locality where the temperature was fairly high After eight years the alcohol content had increased from 56 to 75% He explains this by assuming that the wood of the barrel acts as a dialyzing membrane in which the water is absorbed, the alcohol behaving as a colloid The absorbed water finally evaporates from the outer surface of the barrel To prove his contention he placed a hydro alcoholic mixture in two barrels the outer surface of one being varnished The bunghole of the varnished barrel was left open so as to allow some evaporation After four years the alcoholic content of the mixture was somewhat less The alcoholic content of the mixture in the unvarnished barrel however increased 4-5% in the four year period —P SAUVATRE *Bull soc pharm Bordeaux*, 73 (1935), 111, through *Pharm Weekblad* 72 (1935), 826 (E H W)

Althea Leaves and Root—Evaluation of Many articles have been published basing the determination of mucilaginous drugs on viscosity measurements of the extract However, it is impossible to give a procedure which will be satisfactory for all mucilaginous drugs In preparing an extract of the principles of althea root a minimum of heat should be employed to prevent the solution of starch A 10% extract was prepared as follows The weighed amount of drug was lightly packed in a tall cylinder the necessary amount of water poured on, and allowed to stand at room temperature for one hour Every six minutes the contents were agitated by turning the cylinder through 360° on its horizontal axis It was then poured through cotton and then filtered clear through a double filter paper As the result of viscosity measurements run on numerous samples it may be said that the best results are obtained by macerating a drug all of which will

pass through a 1-mm mesh sieve for one hour at room temperature in a tall cylinder, shaking gently every ten minutes. An evaluation of althca root is suggested. In the preparation of an extract of the leaves, it was shown that the drug should be powdered as finely as possible. Moderate heat increases the viscosity, whereas heating at water bath temperature causes a precipitate and lowers the viscosity. A determination for althca leaves is also suggested.—E WALDSTÄTTER
Scientia Pharm, 6 (1935), 61 (M F W D)

Cherry Laurel Water and Solution of Hydrocyanic Acid—Preservation of, by Paraffin Oil and Official Vaseline. The concluding article on the preservation studies reported earlier (*J Am Pharm Assoc*, Abstract Sect, 29 (1935), 71). A vaseline layer superimposed upon the solution of hydrocyanic acid, protection against light and low temperature (refrigerator) give a stable preparation.—A GUILLAUME and G DUVAL. *Bull sci pharmacol*, 42 (1935), 211 (C T I)

Chloroform—Preservation of, for Use in Anesthesia. One per cent of absolute alcohol was added to chloroform and the product was kept at 20–26° C for 6 months in small colored flasks. On examination at the end of this period the product was clear and had an odor of pure chloroform. Tests for chlorides, chlorine, usual organic impurities, aldehydes, carbonyl chloride, etc., were negative. However, a portion of the above liquid gave positive tests for the impurities named after being subjected to light, and the author concludes that the product should be preserved by the addition of 1% of absolute alcohol and protection from light.—ADELE LISSIEVICI-DRAGANESCI. *J pharm chim*, 21 (1935), 533 (M M Z)

Colloidal Silver (Protargol)—Researches on the Modification of the Physicochemical Properties of, with the Length of Time of Its Preservation. Solutions of protargol are not equally preserved on storing. The concentration of these solutions is influenced but little by the variation of the degree of dispersion of the protargol, on the other hand the quality and the color of the glass of the bottles exercises a very sensitive influence, the greatest decrease in the degree of dispersion being observed when ordinary clear glass is employed. The presence of air likewise presents a considerable effect while its absence affects the degree of dispersion very little. From the sixth day of preservation on, the solutions of collargol showed traces of coagulation. However, from the twentieth day of preservation on a distinct diminution of the degree of dispersion was observed. The samples studied were composed of particles having diameters of 52–60 μ . The viscosity of the solutions varied according to the nature of the samples, the viscosity being the same when the solutions were of the same concentration. In the last case, the variation of the viscosity in the course of preservation was dependent upon the concentration, as soon as the latter was increased, the viscosity varied still more, it declined in a diluted solution, but increased in a concentrated solution (5–10%). The solutions of collargol presented clearly the properties of lyophilic colloidal solutions. The decrease in the viscosity of the solutions of collargol is in general parallel to the lowering of its degree of dispersion. Whatever may be the conditions of preservation, there is an increase in the coloration of the solutions. This variation is not parallel to the modification of the degree of dispersion. The maximum is produced when preserved in the presence of air. This fact is explained by the modification of the properties of proteins destined to stabilize the preparation.—I A FIALKOV and E M NATANSOHN. *J Prikl Khim*, 7 (1934), 328–338, through *Chimie et Industrie*, 33 (1935), 674 (W A P)

Drug Extraction. II. The Effect of Fineness of Powder and of Variation in Solvents on the Percolation of Belladonna Root. In connection with a general study of the fundamental principles of drug extraction, drugs of different types were used. The present report is concerned with the swelling of belladonna root in various solvents and the effect of fineness of powder in various solvents. Measurements were made (with a filar micrometer) of thin strips of cross sections before and after the addition of the solvents. A number of proportions of the following mixtures were tried: alcohol and water, glycerin and water, glycerin and alcohol. In hydroalcoholic liquids increase in alcohol reduced swelling. Alcohol alone had practically no effect. Glycerin alone caused gradual swelling. In mixtures with water, swelling increased with increase of water. For testing fineness of powder Nos 20, 40, 60 and 80 powders were used. For drug containing 10% of moisture, 90 cc of menstruum seemed best to render 100 Gm of drug "evenly and distinctly damp." U S P directions for percolation were used. Various fractions were assayed for total alkaloids and total extractive. Results are tabulated. Within the limits of No 20 and No 80 powder the fineness of powder was of minor importance. Several tables show the results of percolation with various alcohol and water mixtures. As the alcoholic strength in-

creases, extraction of alkaloids becomes more rapid and the yield of extractive greater. Four proportions (alcohol 5, water 1, alcohol 4, water 1, alcohol 7, water 3, alcohol 1, water 1) have approximately the same efficiency, extracting substantially all the alkaloid. Menstruum for U S P fluidextract appears to be well chosen. Swelling of the belladonna is discussed in connection with the swelling of chestnut wood reported in a previous experiment—WILLIAM J HUSA *J Am Pharm Assoc*, 24 (1935), 446 (Z M C)

Drugs—Storage of, New Problems in The proper storage for drugs is of growing importance as shown by (1) The increasing skill in chemical manipulation which has led to the isolation from natural sources and the marketing of remarkably unstable substances with very definite and pronounced physiological action, whose existence was not even suspected twenty five years ago (2) The synthetic preparation of an increasing number of complex organic substances characterized by relative instability in particular the metallic organic medicaments (3) The introduction of new methods of administration, e g, parenteral methods, where the medicament is introduced outside the body's natural defenses, often in massive doses (4) The decomposition of drugs which may be initiated by methods of sterilization. A study of the properties of insulin will indicate how easily substances of this class are inactivated. Studies on vitamin A indicate that the factors essential for stability should be the absence of oxygen, low temperature, choice of suitable vegetable oils as a solvent. Vitamin C may be kept in preserved fruit juice which has been tyndallized in the absence of air. Evidence collected shows that solutions of irradiated ergosterol in olive oil prepared under certain defined conditions and kept at 0° C retain their activity unchanged for two years but are liable to lose their activity slowly at room temperature. It is important that preparation be carried out under well controlled conditions, as the stability of various makes appears to be different probably due to the difficulty of removing traces of oxygen during irradiation. A knowledge of the stability of metallic organic compounds of arsenic, gold, bismuth, antimony and mercury is essential owing to the ease with which changes may occur in their constitution. Special care must be taken to prepare fresh solutions of these metallic substances, and they should also be kept in an inert atmosphere. Sterilization, bacterial infection, chemical changes, oxidation, autooxidation and actinic reaction are other factors which influence stability—J E BOWEN *Pharm J*, 134 (1935), 351 (W B B)

Galenical Tinctures of D A B VI Intimate Knowledge of the Tincture The eight various menstrua used in the preparation of the 41 tinctures are listed with examples. The official definition as given in the D A B is discussed literally. Vinegars are also included. *Types and reasons for the Spontaneous Changes in Tinctures*—For a complete understanding the knowledge of the causes of turbidity and of the deposits in the tinctures is necessary. Likewise a knowledge of the solubilities of the constituents of the drug in the menstruum used and the temperature of manufacture is required. Variation in temperature of the tincture stored may be different from that of the manufacturer but sufficient to cause a sedimentation. Changes by oxidation and reduction may be due either to external factors such as sunlight, or internal factors, by certain constituents such as ferments, enzymes, hormones or vitamins. *Old and New Possibilities of Examinations*—The author cites physico-physiological properties grouped to distinguish tinctures such as color, color and odor and color and taste. Some tinctures possess all three attributes. The comparison of the color tone to a color scale, e g, Ostwald color scale, is preferred. The residue remaining after evaporation of the tincture may be used as a test. The alcohol number, i e the cc of alcohol in 10 Gm of tincture determined after saturation with potassium carbonate, is a newly introduced test. The author reviews certain documents on the history of the introduction of capillary analysis as a means of detection in pharmacy and cites Friedrich Goppelsroeder as the Father of Capillary Analysis—HERMANN KUNZ-KRAUSE *Pharm Zentralk*, 76 (1935), 174, 205 (E V S)

Iodine—Antiseptic Power of Certain Solutions of This is a confirmation of the work of LaWall and Tice and of Karns. The tinctures of iodine usually employed are much too concentrated, the formula containing iodine 2 Gm, potassium iodide, 24 Gm, and diluted alcohol (about 50%) a sufficient quantity to make 100 cc, possesses a raised germicidal power, does not irritate the skin and penetrates easily. has a saline concentration near that of the serum, mixes perfectly with water and answers all needs—T SATRIANO *Ann Farm Biochim* 5 (1934), 37-50, through *Chimie et Industrie*, 33 (1935), 674 (W A P)

Iodine Ointment—Non-Staining During the course of the examination of a number of

samples of non staining iodine ointment a large variation in iodine content was noted. Investigations were carried out regarding the absorption of iodine by different bases under varying conditions. Iodine is only slowly absorbed by a base of melted vasoline (B. P. 1923) and prolonged heating is necessary to effect combination. This results in the loss of a large proportion of iodine, especially if an open vessel be used. The National Formulary (Great Britain) directs the iodine to be rubbed down with arachis oil in a warm mortar until solution is effected. Melted soft paraffin is then added and the whole thoroughly mixed. A sample made strictly according to these directions does not result in a non staining preparation. On heating there is a further gradual absorption of iodine by the base, but at the same time loss of free iodine occurs. The directions given by the B. P. C. 1934 are to mix the iodine with the arachis oil, add the yellow soft paraffin and heat gently with occasional stirring at a temperature not exceeding 60° until complete combination is effected, as indicated by the disappearance of the brown color. However, complete combination is not a practical proposition nor is it necessary in order to produce a non-staining preparation. Further, contrary to the B. P. C. statement, the disappearance of the brown color is not an indication of complete combination—the brown color disappears when the free iodine falls below about 0.7%. During the manufacture of the N. F. and B. P. C. 1934 ointments a dark brown resinous substance is produced which sticks to the sides and bottom of the vessel. The formation of this substance results in a serious loss of iodine, since 17.26% iodine was found in the alcohol soluble portion of the substance, and 4.46% iodine in the alcohol insoluble portion.—R. W. RICHARDSON
Pharm. J., 134 (1935), 589 (W. B. B.)

Kaolin—Emulsifying and Suspending Power of an Extracoloidal, "Kaolin Blanc Extracoloidal Suspensiv" (Gignoux & Co., Lyon, France). This product consists of particles 250 times smaller than the finest baryte and 20 times smaller than the regular colloidal kaolin, possesses unusual water absorptive power, remains suspended in water, stabilizes emulsions of both types inactive, tasteless and odorless. For liquid emulsions 1–5% is necessary, for pastes or thick emulsions at least 7% and it must always be added to the water. For concentrations to 7% an egg beater may be used to bring about dispersion, if mechanical stirrers are used concentration to 17% may be obtained. It is used as an absorbing, wetting and gelatinizing agent in various pharmaceutical and cosmetic preparations such as toothpastes, skin salves, antiseptics, disinfectants, for emulsification, suspension and dispersion of pigments, oils, waxes and resins, as an adhesive thickening and emulsifying agent for creams, face milks and liniments, as an extraction medium for pomades and drugs and in a dry condition for shampoos and face powders.—*Reichstoff-Ind. Kosmetik*, 10 (1935), 112 (H. M. B.)

Ointment Making. Bases include the two forms of wool fat, petrolatum, absorption bases from lanolin, benzoated lard, cold cream and greaseless bases from glyceryl monostearate or vanishing cream. Anhydrous is seldom used alone and petrolatum is added to it to make it spread easily. Ointments for the face, sunburns, etc., are often made with cold creams or greaseless cream bases. Lanolin and its bases are employed when quick penetration is desired, petrolatum when slow action is wished. Lanolin has supplanted benzoated lard which is not so easily absorbed and tends to become rancid. Hydrogenated oils as cottonseed are being used for tin ointments to which they impart good body, spreading qualities and sufficient absorptiveness for ordinary purposes. Waxes are added only to give body, beeswax is preferred since it makes the ointment less granular, cocoa butter is often added for emollient effect. Other bases used which are not so desirable are glycerite of starch and casein cream. The function of an ointment is to (1) promote healing, (2) allay pain and (3) protect the affected area from infection and the air. Effective antiseptics are mercury salts and phenols. The details of commercial manufacture are given—*ANON. Drug and Cosmetic Ind.*, 36 (1935), 687–688 (H. M. B.)

pH—Pharmaceutical Study of. This concludes a report begun in the previous *JOURNAL*, taking up first pH and stability of galenical preparations. A considerable number of the various findings are reported. With ergot preparations there are also contradictory statements. Confusion in literature is increased by the undependable results of various assay methods. Six investigators have concluded that pH of the fluidextract and alkaloid solutions should be adjusted to about 3.0 but they do not agree about which acid is best. Others think this figure questionable. Adjusting hydrogen ion concentration has been quite successful with aconite preparations. Swanson did the original work recommending that pH values of tinctures and fluidextracts be adjusted between 2.5 and 3.0. Among miscellaneous vegetable preparations which can be im-

proved by adjusting p_H are Compound Tincture of Gentian, preparations of veratrum, gelsemium, nux vomica and B P Compound Tincture of Cardamom. Scoville has studied a large number of tinctures of lesser importance, precipitation being increased in some, retarded in others. Miscellaneous chemical preparations have had considerable study. Some of these are Syrup of Ferrous Iodide and Syrup of Hydriodic Acid, solutions of arsenous iodide, solutions of potassium arsenite, Donovan's Solution, Solution of Iron and Ammonium Acetate, Iron and Ammonium Citrate, Solution of Magnesium Citrate. Fungous growths in Acid Solution of Phosphates can be prevented by addition of acid and precipitation in Compound Elixir of Glycerophosphates was reduced by addition of lactic acid. P_H affects color of Elixir of Ferric Pyrophosphate. P_H of Spirit of Ethyl Nitrite changed greatly during deterioration. Various hypochlorite solutions show much variation in p_H . There is evidence that hypochlorous acid ionizes in an amphoteric manner. P_H is an important factor in the stability of alkaloids during sterilization, p_H of solutions for injection must be stabilized to a value comparable to p_H of blood. Buffering to the physiological p_H , solutions of morphine, cocaine, tutocaine and larocaine for injection is important. Decomposition of morphine at high temperatures and at different p_H values has had considerable investigation. Cocaine requires an acid medium for stability. Various investigations are reported. Dissociation constants for cocaine and its hydrolysis products have been determined. The results are given. Other alkaloids discussed are procaine, atropine, homatropine, cinchona alkaloids, hydrastine, physostigmine and pilocarpine. Miscellaneous organic compounds studied were sodium luminal, thiosulphates, benzyl alcohol solutions, urotropin solutions, strophanthin solutions, iodoform in solution, hydrogen peroxide solutions, phenol neoarsphenamine. Fundamental principles not yet of practical value have been established. Ions which are in an adsorbed state have reaction qualities different from free ions. Hydrogen-ion concentration measurements on synthetic solutions in connection with pyrophosphates have been of value. The presence of a transition point at p_H 4.3 between the two types of oxidation, addition of oxygen and evolution of hydrogen has been demonstrated. A number of p_H values for the maximum stability against hydrolysis of esters have been determined and some of these are given. Olivier has claimed that the influence of the hydrogen ion concentration upon hydrolysis is conditioned by the nature of the compound. A bibliography of more than 300 references is appended.—FREDERICK F JOHNSON *J Am Pharm Assoc*, 24 (1935), 498 (Z M C)

Pills—Adsorptive Properties of Substances Used in the Preparation of The author summarizes his work as follows: 1. Of the vegetable constituents employed in the preparation of pills the greatest adsorbing power in relation to strychnine is found in althaea and licorice roots. 2. The adsorbing properties of a dandelion powder are insignificant, they are lower than those of yeast extract. In the preparation of pills with strychnine it is most rational to use dandelion root as the inert constituent. 3. The vegetable constituents employed in the preparation of pills cannot be looked upon as indifferent, because adsorbing the therapeutic substance from the pillular mass they influence the pharmacodynamic effect of the therapeutic agent. 4. Considering the change in conditions of the pharmacological activity of therapeutic substances it is necessary to work out exactly the nature of constituents employed in the preparation of pills, so as to know what vegetable constituents must be used for a given substance. 5. Pills containing alkaloids must not be kept for a long period of time.—T TSCHERIKOWSKYA *Sovets Pharm* (1935) 1-7 (A S S)

Plants—Ultrafiltration and Its Application to the Extraction of the Active Principles of A description of the preparation of ultra filters. The active principles of belladonna, hcnbanc and strophanthus pass through an acetate collodion filter, of porosity calculated to let pass only crystals. As Graham understood that term, and can thus be obtained in a very pure state.—L I BRACCIO *Boll chim farm*, 74 (1935), 185, through *Chem Abstr*, 29 (1935), 4517

Propylene Glycol—Use of, As a Solvent Experiments were carried out to ascertain the value of propylene glycol as a solvent for pharmaceutical use. From the results of these experiments, it appears that propylene glycol is not as good a solvent as ethylene glycol of defatted cochineal but in the case of cudbear it is superior. Propylene glycol is a solvent of the constituents of aloes which react with ammonia, and of the tannins in catechu. It is suggested that further work should be done to test the non toxic properties accredited to propylene glycol.—J RAR *Pharm J* 134 (1935) 590 (W B B)

Pyrethrum—Deterioration of The loss of insecticidal activity of pyrethrum is due to

oxidation and is activated by light. It can be partially inhibited by hydroquinone or tannic acid. Some slow loss of potency occurs during storage, the cause of which is unknown. Extracts dissolved in kerosene and other inert solvents are fairly stable. Strong soaps and alkalis may be deleterious because they hydrolyze the esters.—F TATTERSFELD *Chem Trade J*, 96 (1935), 273, through *Squibb Abstr Bull*, 8 (1935) A 937

Raspberry and Strawberry Flavors Raspberry extract may be prepared by pulping the fruit allowing it to ferment with sugar at 25–30° and concentrating by distillation, sugar and acid should be in ratio of 100 : 47. Addition of vanillin or vanilla extract is desirable. Cheaper extracts may be fortified with synthetics such as iso butyl formate, or acetate, iso butyl acetate, iso amyl butyrate and iso butyrate. Other substances used in large proportions are ethyl formate butyrate, iso butyrate, oenanthe, iso amyl acetate and acetaldehyde. Small quantities of clove oil and alpha ionone and traces of ethyl benzoate, neroli oil, terpeneless lemon oil, cinnamon oil, orris oil and methyl salicylate have also been recommended. In the case of strawberries, the fermentation process is omitted and the alcohol recovered by distillation *in vacuo*. It should be fortified by the addition of ethyl methyl phenyl glycidate ("Aldehyde C16"). Traces of methyl salicylate and pimento oil, coumarin with or without vanillin and the following esters may be employed: iso amyl butyrate, and iso butyrate, ethyl formate, acetate, butyrate, iso butyrate, pelargonate, benzoate and cinnamate, iso amyl formate and valerate, benzyl acetate and valerate. Other constituents are benzaldehyde, eugenol, clove oil, cinnamon oil, neroli oil, terpeneless orange oil, orris oil and cognac. The sugar to acid ratio should be 100 : 16.—H STANLEY RED-GROVE *Am Perfumer*, 30 (1935), 193–194, 222 (G W F)

Solution of Adrenaline (1–1000)—Practically Neutral, with Good Keeping Qualities. The following formula is recommended: Adrenaline 1 Gm, *N* hydrochloric acid 5.45 cc, solution of sodium bisulphite (d 1.33) 5 cc, sodium chloride 7 Gm, water enough to make 1000 cc. The amount of hydrochloric acid used is the quantity theoretically required to form the hydrochloride of the adrenaline, and the *pH* of the solution is 3.8.—LOUIS JULIEN *J pharm chim*, 22 (1935), 53–59 (S W G)

Solution of Bismuth and Ammonium Citrate, B P C 1934. It is suggested that 20 cc of distilled water be used in preparing Liquor Bismuthi et Ammonii Citratis B P C for mixing the citric acid and the bismuth subnitrate, instead of 2 cc as stated by the B P C. Also, more detailed instructions regarding the washing of the bismuth citrate should have been given in the B P C regarding this solution.—R D KOTWAL *Pharm J*, 134 (1935), 564 (W B B)

Solutions—Sterilization of, for Injection. Many drugs intended for parenteral administration are of a heat labile nature, the heat stability varying with the drug under consideration. The degree of thermostability and the loss in activity of the solutions during periods of storage at ordinary temperatures are closely related problems. All apparatus used in the preparation of Solution of Adrenaline Hydrochloride B P must be sterile, and, together with the ingredients, should be free from alkali, iron and ammonium salts. A routine method for preparing this solution is to dissolve the chlorbutol and sodium chloride in 90% of the finished volume of hot sterile distilled water, stopper the vessel with a sterile rubber bung and allow to cool. Place the adrenaline in a small bottle, displace all the air by an inert gas such as nitrogen and add a few cc of sterile distilled water followed by the hydrochloric acid measured from a sterile pipette. Pour this solution into the solution of chlorbutol and salt, rinse the smaller vessel with several quantities of sterile distilled water, add to the main solution, make up to volume, displace all air from above the solution, stopper and mix well. In regard to solutions of morphine salts, the *pH* value, often a good guide to the extent of decomposition, gives little assistance, a highly decomposed sample having a *pH* showing little variation from a normal solution. It seems, however, that the change is one of oxidation and a more stable solution may be made by preparing it under aseptic conditions, with the total exclusion of atmospheric oxygen. A satisfactory 50% solution of dextrose has been prepared by the routine method of dissolving the requisite amount of dextrose B P in an equal quantity of boiling distilled water contained in alkali-free resistance glass apparatus. The solution so obtained is filtered through a bed of fine kieselguhr on a Buchner funnel and corrected to volume when cold by a further suitable addition of water. It is then ready for sterilization at 10 pounds for half an hour.—H GARTSIDE *Pharm J*, 134 (1935) 507 (W B B)

Sterile Solutions—Preparation of Some. Detailed directions are given for preparing sterile solutions of the following for intravenous therapy: camphoric acid and salts, camphorcarboxylic

acid and salts, camphor-thiocarboxylic acid and salts, ($p\text{-CH}_3\text{C}_6\text{H}_4\text{S}$), naphthoresorcinol and hydrin, sodium polythionates, quinine, copper and urotropine salts, tetraglycolyl orthosilicate dyes, diphenyl derivatives, erythritol tetranitrate and nitroglycerin —E CHIERICI *Boll chim farm*, 74 (1935) 145, through *Chem Abstr*, 29 (1935), 4516

Sterilization Notes The article contains a summary of the conclusions from discussions on papers on sterilization. In brief, the conclusions are (1) Ampuls must be previously cleansed and sterilized by hot air at 160° for two hours, (2) distilled water should be used, (3) neutralized and sterilized oil must be used for oily liquid injections, (4) greatest of aseptic conditions should be observed, (5) autoclaving at temperatures between 110° and 120° for fifteen to twenty minutes is the perfect method of sterilization, (6) bacteriological control should be maintained over preparations if filters are used, (7) neutral glass should be used for ampuls (8) stocks should be renewed frequently —ANON *Pharm J*, 134 (1935), 384 (W B B)

Sterilization Notes Samples of olive oil and almond oil, submitted to sterilization by heating to temperatures of 150°C to 155°C for one hour, were examined at intervals in order to detect any effects due to heating. Sterilized olive oil showed considerable loss of color and had developed a greenish shade. Almond oil was slightly less colored than an untreated sample. The acid value of the two oils, after treatment, was the same as before treatment. No increase in the acidity was noticeable at weekly intervals for a month. The conclusion is that the treatment causes no subsequent deterioration. R A O'Brien and H J Parish state that the accumulated experience of some years convinces them that heating contaminated oil to 150°C for an hour ensures sterility, whatever the contamination. They also state that "the prescribed method of Tyndallization may fail to sterilize contaminated oils." Novocaine dissolved in 0.001N hydrochloric acid is stable when sterilized in a current of steam, and hydrolysis on autoclaving is not more than 2%. Hydrogen-ion concentration is not affected by sterilization. The pH value of novocaine solutions should not be more than 5. Ampuls for novocaine solutions should be made of Jena glass, since the action of a minute quantity of alkali on an unbuffered solution can alter the pH value and cause strong hydrolysis —ANON *Pharm J* 134 (1935), 647 (W B B)

Suppository Mold—Apparatus, Small Scale, for Pharmaceutical Manufacturing The mold, made of a nickled brass alloy, prepares 100 suppositories and weighs about 6 Kg. The form is divided horizontally into two halves at a point where the suppository has the greatest diameter. The two halves fit together by four guide grooves with springs at the corners, and are tightened by

two wing nuts. The method of assembling and using the mold, as well as the proper preparation of the suppository mass, is described in detail —GÄRTNER and SCHENKER *Schweiz Apoth Ztg* 73 (1935), 357 (M F W D)

Tincture of Ginger, Strong The last British Pharm reinstates Tinct Zingib Fort after its having been omitted from the two intermediate issues. The changes after an interval of nearly fifty years are practically negligible, "moderately coarse powder" replaces "fine powder," directions for the process of percolation have been deleted and metric weights and measures are used —C E DODSLEY *Pharm J*, 134 (1935), 602 (W B B)

Water-Sterilization of, by a New Quartz Lamp An apparatus is described for the sterilization of water and such oils as cod liver, soya bean, rape, etc —Rieschstoff *Ind Kosmetik* 10 (1933) 111 (H M B)

PHARMACOPŒIAS AND FORMULARIES

Pharmaceutical Formularies and the Belgian National Formulary A historical review of the formularies and dispensaries of many countries with special emphasis on the Belgian publications—O VAN SCHOOR *J pharm Belg*, 17 (1935), 383-388, 405-410, 430-434 (S W G)

Pharmacopœial Questions from Practitioners Two preparations of the Swiss Pharm V—Tablets of Ipecac and Opium and Pastilles of Sodium Bicarbonate—are considered The formula of the first differs considerably from that in the fourth edition and should no longer bear the synonym Vigner Tablets The title of the second preparation should be Compound Pastilles of Sodium Bicarbonate—J B L *Schweiz Apoth-Ztg*, 73 (1935), 321 (M F W D)

Pharmacopœias—The Oldest of Switzerland A brief history of some of the outstanding pharmacopœias is given The earliest ones were private enterprises, the first appearing in Basle in 1561 Before this the mention of drugs was made in price lists, the first of these being dated 1404 Pharmacopœias as such are of comparatively recent origin The first Swiss Pharm appeared in Latin in 1865, the second in 1872, the third in 1893 and the fourth in 1907 The earliest record of an apothecary shop is found in Basle in 1250—ANON *Schweiz Apoth Ztg*, 73 (1935), 269 (M F W D)

U S P Revision The Committee of Revision of the Pharmacopœia of the United States 1930-1940 has issued the U S P X Interim Revision Announcement No 4, which includes revised or new texts for Magnesia Magma, Oil of Lemon, Non destearinated Cod Liver Oil, Large Poison Tablets of Mercury Bichloride and Small Poison Tablets of Mercury Bichloride The tests become official on October 1, 1935 The revised text omits the manufacturing details for milk of magnesia, but adds more exacting requirements for uniformity and purity than were in the old text, these being capable of enforcement through appropriate tests For purposes of minimizing the action of magnesia magma on glass containers, 0.1% of citric acid may be added The modification of the standards for oil of lemon brings them into conformity with new developments in manufacture and authorizes the official use of a domestic oil of lemon Increasingly large importations of so-called "undestearinated cod liver oil," for subsequent destearination, made desirable appropriate standards and tests of this non destearinated cod liver oil The poison tablets of mercury bichloride must be of a distinctive color (not white) and shall be of an angular or irregular shape (not discoid) When sold in quantities for household use they should be dispensed in glass containers of a distinctive angular shape, having irregular or roughened sides or edges On the exterior of each container must be placed a red printed label bearing the word "Poison" and a statement indicating the amount of corrosive mercuric chloride per tablet—ANON *Pharm J* 134 (1935) 748 (W B B)

NON-OFFICIAL FORMULÆ

Cellulose Varnish A varnish containing, *e g*, benzylcellulose 5-18, benzine 18-40, toluene or xylene 25-45 and butyl acetate 20-35% or benzylcellulose 2-12, benzine 50-80 and ether 25-80% used for pharmaceutical or toilet purposes, is contained in a collapsible tube and used as required—J WALD and G LEGRAND *French Pat*, 777 999 (Mar 6, 1935), through *Chem Abstr* 29 (1935), 4526

Cleansing Cream Containing Magnesium Hydroxide A cleansing cream which is solid at room temperature contains beeswax 1-6, petrolatum 30-60, mineral oil 30-60, free magnesium hydroxide 0.5-6.0 and water 10-30% U S Pat 1 999,161 relates to a skin cream comprising petrolatum, a cholesterol alcohol, ceresin wax, magnesium hydroxide and water—BRUCE WALTON (to Chas H Philips Chemical Co) U S Pat 1 999,160 (April 23), through *Chem Abstr*, 29 (1935), 4136

Cosmetic Pomade A pomade contains paraffin 40, camphorated oil 24, camphorated alcohol 130, sulphur extract 1 Gm and tincture of iodine 40 drops—F BALZARELLI and C BALDINI *French Pat*, 778,236 (Mar 12 1935), through *Chem Abstr*, 29 (1935), 4526

Cosmetics—Progress in, in 1934 A discussion of the progress made in 1934 in producing new shaving, hair and skin creams, face lotions and packs, sunburn and suntan preparations, depilatories eye and lip cosmetics bath, tooth and mouth products is offered—KARL PFAFF *Reichstoff Ind Kosmetik* 10 (1935), 88-92 (H M B)

Dentifrices Oils, fats or waxes are used as means for giving to the preparations the desired consistency Examples contain (1) liquid paraffin 200, gum tragacanth 20, soap 30, sodium

perborate 30, saccharin 0.5, essential oils 2 and calcium carbonate 250 Gm, and (2) olive oil 1200, potassium acid phosphate 20, gum tragacanth 20, saponite 20, saccharin 0.5, essential oils 2 and calcium carbonate 250 Gm —G BEHR French Pat, 778,232 (Mar 12, 1935), through *Chem Abstr*, 29 (1935), 4525

Derris Root—Uses of Derris is effective against the following parasites many caterpillars, probably all larvæ of leaf-eating wasps, many beetles and their larvæ, turnip fleas, flower wasps, plant lice and red spiders. It is of no value against wasps, adult flies and moths, certain kinds of caterpillars, many beetles and scale insects. The powdered root, mixed with 40 parts of talc, makes a very good insect powder for dogs and cats —*Ber Afd Handelsmuseum Kon Ver Kol Inst* (1934), 90, through *Quart J Pharm Pharmacol*, 8 (1935), 300 (S W G)

Face Powders—Trends in A sample of face powder taken from an early Roman tomb analyzed by the British Museum was found to be much like modern powders and to contain talc, lead carbonate, chalk and clay. In the intervening period little has been done but to eliminate the poisonous ingredients and to better balance the properties. Recent discoveries take two forms (1) face powder bases and (2) the substitutes. The former are really ingredients intended to improve slip and because of their adhesiveness to supplant stearates, others are intended to provide better covering power and adhesiveness, the slip being provided by talc. The substitutes are intended to provide all of the necessary properties of a face powder, i.e., covering power to a correct degree, slip, adhesiveness and sufficient absorbing power to hold perfume and color. The outstanding property to be concerned with is covering or hiding power. There is a real demand for a powder which does not become translucent and some new bases have been developed to utilize the principle of diffusion of light through the use of uniform infinitely fine (10 microns or less) particles of a particular shape rather than depend upon the reflection of light from varying percentages of opaque pigments —F CHILSON *Drug and Cosmetic Ind*, 36 (1935) 685-686

(H M B)

Grease Paints Grease paints are made up of two main constituents, namely, a dry base and a fat base. The dry base is selected from raw materials such as zinc oxide, kaolin, precipitated chalk. The more expensive dry bases are titanium oxide and subnitrate of bismuth which are used in high class grease paints. The fats used for the fat base have to be so selected that the product will only melt at a temperature higher than that of the blood. The fat base should be made up of selected material such as hard paraffin, soft paraffin, liquid paraffin, beeswax, lanolin and oils such as kernel and almond oil. The adhesion of the grease paint to the skin of the face is one of its main features. The perfume is added to the fat base, and the coloring matter to the dry base. Thorough incorporation of the one base with the other is absolutely essential, and any failure in this respect would ruin the entire composition —A G AREND *Perf Ess Oil Rec*, 26 (1935), 254

(A C DeD)

Hair Dyes—Manufacture of A discussion of the manufacture of hair dyes including the system of preparation and the examining of the dyed hair is given —A G AREND *Perf Ess Oil Rec*, 26 (1935), 211

(A C DeD)

Hair Lotion The lotion contains alcohol 420, camphor 15, ammonia 22, turpentine oil 40 and camomilla decoction 415 Gm —HENRI FAGNY French Pat, 776,966 (Feb 8, 1935)

(T G W)

Hormonöl Supra (Chemische Laboratorium Dr Kurt Richter, Berlin) is the pure oil of *Chelonian Atheræ* Sp *Spharigida* (giant turtle oil?) from Mexico. The oil penetrates the epidermis of the human skin extending through the corium to the subcutaneous tissues. It represents the most natural and strongest astringent known being completely absorbed by the human skin. It closes large pores and removes wrinkles. Since the oil is drying it may be used as such for oily skins, for dry skins, however, it should be used with about 10% vegetable oil (almond oil). The following formula for a skin cream is offered: Hormonöl Supra 20%, white American petrolatum 15%, lanolin 10%, Hydrocerin 10%, spermaceti 5%, water 45%. To obtain the maximum astringent action a cream should contain at least 20% of the oil. In preparing the cream do not stir any more than is necessary for emulsification, no more air than is necessary should be introduced. Since the oil begins to decompose at 35° C it should not be heated over a direct flame and in a cream the oil should be added when the mass has cooled to this temperature. The value of the oil depends upon its high vitamin content and the presence of certain hormones which have a specific action on slackened cellular tissue. It may be substituted in part for oils used in fatty or

night creams and also enter the composition of nourishing, wrinkle and other creams—*Riechstoff-Ind Kosmetik*, 10 (1935), 111–112 (H M B)

Lanolin and Its Uses The following formulas are suggested *adepts lanæ cum aqua* adeps lanæ 75%, distilled water 25%, *pharmaceutical lanolin ointment* adeps lanæ anhydr 65, distilled water 20, mineral oil 15, *lanolin cream* petrolatum 100 Gm, lanolin anhydrous 300 Gm, water 600 Gm, *lanolin cold cream* fatty almond oil 4200 Gm, white beeswax 600 Gm, spermaceti 600 Gm, lanolin 1800 Gm, stearin alcohol 200 Gm (may be omitted), water 2800 Gm, borax 50 Gm, *boroglycerin lanolin prescription* A Dissolve 10 Gm boric acid with heat in 40 Gm glycerin and add 200 Gm water B Paraffin 200 Gm, liquid paraffin 500 Gm, anhydrous lanolin 50 Gm, stearin alcohol 20 Gm, cholesterol 10 Gm Fuse one with another until solution results In perfuming lanolin creams too delicate odors do not permeate while stout strong odors are too rough The following are suggested chypre, violet, honeysuckle, benzyl acetate, certain hyacinth compounds and aldehydes Lanolin powders may be prepared by dissolving lanolin in acetone and incorporating with the powder, or by fusing lanolin 10, stearin alcohol 1 and mineral oil 5, slowly adding 20 Gm water containing 1 Gm potassium stearate, cooling, adding 50 Gm of water to form an emulsion Add this to 300 Gm powder, dry, pulverize and sift In superfatting soaps 5% of lanolin is easily absorbed by soaps It causes reduction in lathering power which may be corrected by addition of coconut oil, triethanolamine (2–5%) or stearin alcohol (2–5%) Lanolin promotes water in oil emulsions—JOSEF AUGUSTIN *Am Perfumer*, 30 (1925), 187, 188, 192 (G W F)

Mouth Wash Powders The powders comprise a stabilized oxygen-yielding compound mixed with a silver containing compound and preferably also with an acid substance The oxygen yielding compound, e g, urea-hydrogen dioxide, alkali peroxide-pyrophosphate, alkali perborate or percarbonate, is preferably free from water of crystallization and is stabilized in known manner e g, with magnesium silicate The silver compound may be an inorganic salt, e g, silver nitrate, silver sulphate or the silver chloride ammonium compound or an organic salt, e g, silver acetate, or the benzoate, salicylate, or *p* hydroxy benzoate Citric, tartaric, boric or phosphoric acid, etc, or acid compounds, e g, acid phosphates are used preferably in such proportion as to neutralize only 40 to 60% of the alkalinity of the oxygen yielding compound Flavorings and perfumes may be added In an example, dehydrated sodium borate 30 is mixed with the silver salt of *p*-hydroxy benzoic acid 1.6 and tartaric acid 11.25 Gm—*Deutsche Gold- und Silber-Scheideanstalt vorm Roessler* Brit Pat, 421,692 (Dec 28, 1934), through *Chem Abstr*, 29 (1935), 3785

DISPENSING

Apomorphine Hydrochloride—Preparation of, for Injection The Spanish Phar method gives the most stable solutions Although present methods do not yield solutions which are permanently colorless, there is no loss of activity associated with the appearance of the green color—D PONTE *Giorn farm chim*, 84 (1935), 53, through *Chem Abstr*, 29 (1935), 4517

Arsenical Fowler Solution The author discusses the change in formulas for Fowler Solution involved in the third and fourth editions of the Belg Phar In the B P III the formula was Arsenic trioxide 1 part, Potassium carbonate 1 part, Water 2 parts This was changed in the B P IV to, Arsenic trioxide 1 part, Potassium bicarbonate 1 part, Water 2 parts The chemical reactions involved in the preparation of Fowler Solution are discussed with several references to the literature—G VERSCHURE *Pharm Tijdschr Nederland-Indie* 13 (1935), 41 (E H W)

Bakelite Containers In order to utilize bakelite ointment jars, it is not sufficient to see that they are not attacked Attention should be given to the ointment itself which may undergo alterations, especially modifications of coloration This is noticeable in phenolic preparations It is necessary to direct the attention of the manufacturers of bakelite to these facts—BUCCI and SCHENKE *J suisse pharm* No 20 (1935) 242, through *J pharm Belg*, 17 (1935), 511 (S W G)

Calcium Gluconate for Injection Various methods of manufacturing calcium gluconate are mentioned The method of preparing solutions for injection as used by the firm of Merck Darmstadt, is as follows calcium gluconate, pure, for injection "Merck" is dissolved in the proper amount of water by warming and then heated under a reflux condenser for two to three hours The warm filtered solution is then run into carefully rinsed and sterilized ampuls being sure that

none of the liquid remains in the neck of the ampul. The ampuls are then sterilized for one hour at 100° on at least three successive days —C A ROTHENHEIM *Pharm Acta Helv*, 10 (1935), 114 (M F W D)

Capsules—Accuracy and Speed Factors in Methods employed in determining contents of capsules are (1) dissolving contents of capsule and subsequent evaporation of solvent, (2) assay of ingredients, (3) emptying contents and weighing, (4) using empty capsule as counterpoise, (5) weighing a number of filled capsules at the same time using an equal number of empty shells as a counterpoise, changing empty shells for others after one or two operations. Objections are enumerated. One manufacturer said that the weight of empty shells of the same lot rarely varied more than 3% of the average weight. Empty shells made by different manufacturers may show a difference in wall thickness and hence in weight. One said that a 10% error would be the maximum. A table shows results obtained by weighing different batches taken at random from stock. Another table shows two methods. Two prescriptions of 12 capsules each were used. With one each capsule was weighed on an analytical balance and the average weight of the same size empty capsule subtracted, with the other the contents of the capsule were emptied on a tared watch glass and then weighed on an analytical balance. In both instances results were near theoretical. Of the three general methods for filling capsules, weighing each capsule is most accurate but is impractical for ordinary dispensing. The other two, "the punching method" and "the blocking method" are considered. Factors to be taken into consideration in any comparison are quantity of material per capsule, nature of material, use of the same prescription. Five prescriptions were filled, each by the two methods by the same operator. Tables show the results obtained. A 10% variance was arbitrarily selected, either plus or minus, from the theoretical average weight. The tables show a striking uniformity in the degree of accuracy obtained by average operators working under ordinary conditions by either punching or blocking methods. The punching method required about one-third less time. Of the 100 prescriptions filled only nine were within the 10% limit of variance, five of them filled by punching, four by blocking. The author concludes that comparative accuracy between blocking and punching is in direct ratio to the skill of the operator. Less time is required in punching than in blocking and with a comparable degree of accuracy. Results of the study indicate that a tolerance of more than 10% should be established. Average weight of an empty capsule obtained by the method described may be used as a tare in determining weight of filled capsules —JOHN W LEE *J Am Pharm Assoc*, 24 (1935), 469 (Z M C)

Chloral Hydrate Suppositories—Preparation of For preparing suppositories containing from 0.1 to 1.0 Gm chloral hydrate in each, the author suggests the following: the powdered chloral hydrate is mixed in a mortar with one third of the "Astrafat"; the other two thirds of the mass melted and added the whole mixed, and when of proper consistence poured into chilled molds. A series of suppositories containing up to 1.0 Gm of chloral hydrate in each was prepared and the solidification and melting points tabulated. After two days the suppositories showed no crystals of chloral hydrate under the microscope. An investigation of chloral suppositories made with hydrogenated peanut oil of the Swiss Pharm. V, showed them to be too soft and not easily removed from the mold —H LEHMANN *Schweiz Apoth-Ztg* 73 (1935), 297 (M F W D)

Error in Dispensing—Margin of Determination of the Reasonable or Permissible V Liquids. Though liquid prescriptions are usually measured, possibilities for error are greater than commonly held. Most of them are too small to be of practical significance. The three considered in this study in the order of importance are (1) the nature of the liquid to be measured, (2) shape and size of graduate used, (3) the personal equation. The first test aimed to determine relationship between size and shape of graduate and magnitude of error. The second test aimed to determine how magnitude of error was affected by physical properties such as color, viscosity. Liquids were measured in both cylindrical and conical graduates by 100 senior students. The liquid was poured from a quart bottle into the graduate, then to prescription bottle, then to a tared container and accurately weighed. Quantities were 10 cc, 25 cc, 50 cc and 100 cc. The magnitude of error is greater with conical graduates. The larger the graduates and the larger the volume the smaller the percentage of error. Error due to personal equation is indefinite and impractical to measure. It is revealed by a definite trend in a series of measurements by an individual. It might be due to defective vision, to natural carelessness or to some other trait. In the second series of tests concerned with physical properties the magnitude of error was in the following order: Distilled Water, Elixir of Iron, Quinine and Strychnine (color), Syrup (viscous character).

Milk of Magnesia (opaque), Castor Oil (oily) Color has a tendency to increase error and so does viscosity The large error for Castor Oil, 4.49%, is doubtless due to the fact that the refractive index is so near that of glass that adherence of the oil is not detected and insufficient time is allowed for drainage The large error with Milk of Magnesia is due to the impossibility of draining Results of the 100 workers are summarized in a table and another table shows per cent deviation from average weight "From the data obtained it appears that twice the standard deviation is a reasonable margin of error for the measurement of the volume of liquids" This would permit acceptance of the following

Shape of Graduate	10 Cc	Distilled Water 25 Cc	50 Cc	100 Cc.	Elixir I. Q. & S. 100 Cc	Syrup 100 Cc	Milk of Magnesia 100 Cc	Castor Oil 100 Cc
Cyl	97%	94%	96%	95%	93%	94%	93%	93%
Con	95%	98%	95%	95%	95%	96%	95%	94%

MARVIN J ANDREWS *J Am Pharm Assoc*, 24 (1935), 477

(Z M C)

Histamine Injection The preparation containing histamine acid phosphate 1 mg, isotonic salt solution 1 cc and phenol 0.005, is used as an antirheumatic The recommended dosage is two to three subcutaneous injections a week for four weeks—*Bull Ch Synd Pharm Seine* (Feb 1935), through *J pharm Belg*, 17 (1935), 404

(S W G)

Hospital Dispensary Methods A brief survey of hospital dispensary conditions, more specifically pertaining to the average time taken per patient at the dispensary stage—*Pharm J*, 134 (1935), 353

(W B B)

Mercury Pill B P 1932—Note on The undernoted modification is suggested for the official formula for Mercury Pill

B P		Modification	
Mercury	33 Gm	Mercury	33 Gm
Syrup	14 Gm	Syrup	12 Gm
Liquid glucose	15 Gm	Liquid glucose	12 Gm
Glycerin	5 Gm	Glycerin	1 Gm
Licorice	33 Gm	Licorice	40 Gm
		Tragacanth	2 Gm

The tragacanth should be mixed with the second portion of the licorice and incorporated in the mass The quantity of glycerin has been reduced because there is enough hygroscopic material even without any glycerin at all—*P BOA Pharm J*, 134 (1935), 356

(W B B)

Methylene Blue Injection The following formula of Dr Raymond is given Methylene blue 10 Gm, sodium thiosulphate 50 Gm, saccharose 97 Gm distilled water enough to make 1000 cc Put up in 2- 5- and 10 cc ampuls for intravenous injections—*Bull Ch Synd Pharm Seine* (Feb 1935), through *J pharm Belg*, 17 (1935), 404

(S W G)

Pill Masses A brief survey is given of the various pill excipients prescribed by the British, Belgian Dutch French, Italian, Jugoslavian, German and Swiss Pharmacopœias The author claims to have satisfactorily prepared a large number of pills using as the liquid excipient a mixture of anhydrous glycerin and glucose The author includes a compilation of the formulæ of the above pharmacopœias for Bland's pills—*C A ROTHENHEIM Schweiz Apoth-Ztg*, 73 (1935) 285

(M F W D)

Vehicles—Compositions for Use as, for Other Substances A silica gel suitable as a vehicle for other substances, e g in therapeutic or cosmetic preparations, is obtained by introducing SiF_4 into an aqueous solution of H_2SiF_6 of Sp Gr at least 1.14, separating the gel formed and washing the gel with water until it ceases to have a H_2SiF_6 reaction The gel contains hydrofluoric acid in adsorptive combination and has disinfectant properties A high hydrofluoric acid content is obtained by using H-SiF_6 of high concentration and operating at a high temperature Temperatures of 0–50° may be used Water or steam may be added during the reaction to keep the H_2SiF_6 concentration constant—*J BLOCH and E BLOCH Brit Pat*, 424,015 (Feb 13, 1935), through *Chem Abstr*, 29 (1935) 4524

PHARMACEUTICAL HISTORY

Apothecaries of the Hague This historical review cites the mention of certain early apothecaries of the Hague in the records of the city Among them are Pieter Willems de Vries 1561

Gregorius van Moersele 1562 and Gregorius de Apothecker 1563 The establishment of an apothecary in the time of Albrecht van Beyeren Colaert van Buristre (or Barastre) in 1397 is also mentioned—A J VAN HUFFEL *Pharm Weekblad*, 72 (1935), 751 (E H W)

Cosmetics in Recent Times—History of The second of a series of articles ALBERT HAUENSTEIN *Riechstoff Ind Kosmetik*, 10 (1935), 95-96 (H M B)

Homeopathy—History of An address reviewing the history of homeopathy—J KATZ *Pharm Zentralh*, 76 (1935) 269, 286 (E V S)

Pharmacy at the Beginning of the 19th Century This article, one of a series on historical pharmacy, describes Dutch pharmacy at the beginning of the nineteenth century Rather of interest is the fact that in 1812 the population of Amsterdam was nearly 200 000 and the number of pharmacists 150 To day the population is four times as large but the number of pharmacists remains nearly the same—A J VAN HUFFEL *Pharm Weekblad*, 72 (1935), 822 (E H W)

United States Patents Granted for Medicines during the Pioneer Years of the Patent Office 'Patent' means open, not secret A patent cannot be granted for a medicine of secret composition and the term "Patent Medicine," applied to medicine of secret composition is a misnomer Patenting a medicine does not preclude telling fairy tales about it, therapeutic claims in the description of some of the patents for medicines are false and fraudulent In this paper some interesting phases in the patenting of medicines are related and the history from its beginning in England is discussed, a number of well-known remedies being mentioned Our Constitution gives the power to "Promote the progress of Science and useful arts by securing, for a limited time to authors and inventors the exclusive right to their respective writings and discoveries" The first law under this provision was enacted in 1790 and provided for a board consisting of the Secretaries of State and War the Attorney-General and the President Thomas Jefferson, Henry Knox and Edmund Randolph made the first board The first patent was issued to Samuel Hopkins to cover a process for manufacturing "Pot and Pearlash" No grant for any medicine was issued under this law A new law was issued in 1893 The first patent dealing with therapeutic matters was issued in 1796 to a physician for a device for removing pain the acme of fraud In 1836, a fire destroyed records patents drawings and designs but Congress had published Indexes which were filed elsewhere and titles of the patents were preserved in this way In 1836, a new law was passed and numbering of patents was begun Between 1790 and 1836 about 75 patents covering pills medicines, ointments and salves were issued These are listed with name of medicine, date and patentee The John Cullen process patent for "Liquid Magnesia" in 1818 was probably the first for a medicine, the product resembles our present solution of magnesium citrate, and even then magnesium compounds were recognized as having aperient properties A photostatic copy of a 'Diaphoretic or Sweating Powder' patent is given and also a summary of other Howard Patents Bitter Tonic, Tincture of Myrrh Compound Antispasmodic tincture, Astringent tincture Others mentioned are Chlorine Cosmetic in 1833, Ointment for Curing Many External Diseases, 1835, Ointment for Cure of Cancer in 1836 Thomson's Improved System of Botanic Practice of Medicine, in 1836 Photostatic copy of a page of the latter is given—LYMAN F KEBLER *J Am Pharm Assoc* 24 (1935) 485 (Z M C)

PHARMACEUTICAL LEGISLATION

Food and Drug Legislation—National The text of a radio address Reference is made to the first step in food and drug legislation in 1850, the passage of the present law in 1906 and the growing recognition of need for its revision S5 popularly called the Copeland Bill contains valuable features of the present law It eliminates provisions that have caused courts to make interpretations that afford avenues of escape for unscrupulous, it extends provisions to cosmetics and advertising it amplifies and reinforces some provisions that safeguard public health it strengthens procedural provisions The Bill contains definitions of foods, drugs and cosmetics The definition of standards are broad If it becomes law the motive of fear upon which much advertising is based should be disposed of because statements of fact are required If there is not sufficient consumer interest it is in danger of not becoming a law—RALPH W CLARK *J Am Pharm Assoc* 24 (1935) 490 (Z M C)

Laws and Orders Regarding Pharmacy in 1934 A review of laws and orders which include general matters sickness compensation management of pharmacies legislature pharmaceutical concessions improvements help the commerce of new remedies spirits serums narcotics, and

statements introducing new remedies, patented medicines, etc.—WALTER SCHMIDT *Pharm Zentrallh*, 76 (1935), 240, 253 (E V S)

PHARMACOLOGY, TOXICOLOGY AND THERAPEUTICS

PHARMACOLOGY

Carotene and Vitamin A—Absorption of A study has been made of the absorption of vitamin A and carotene administered to a patient suffering from a condition which led to part of the contents of the thoracic duct being diverted into the pleural cavities. Analysis of the fluid removed at intervals from the chest cavities enabled approximate estimations to be made of the amount of vitamin A and carotene absorbed by the way of the chyle. It was found that a relatively small proportion of the carotene administered orally could be accounted for by the pigment found in the chylous fluid, whereas in the case of vitamin A, the amount recovered was such as to indicate an almost complete absorption. The vitamin, administered as the free alcohol, was found present in the lymph mainly in the esterified condition, and it is thought probable that the linkage with the fatty acids during passage through the intestinal walls accounts for the much higher coefficient of absorption as compared with that found when carotene was given. Observations on the chylous fluid show that over a range of reaction, much wider than that encountered in body fluids, no trace either of carotene or of vitamin A passed a dialyzing membrane. Both compounds appeared to be present in colloidal form and closely associated with the highly dispersed fat—J C DRUMMOND, M E BELL and E T PALMER *Brit Med J*, 1 (1935), 1208 (W H H)

Castor Oil—Purgative Action of, and Alimentary Disequilibrium Experimental evidence is presented showing that the purgative action of castor oil is due to an alimentary disequilibrium. If the castor oil be introduced into a diet properly balanced, no nutritive disturbances or laxative actions become manifest, the oil is assimilated by the animal. The authors deduce that the truly active principle and very probable cause of purgation is the ricinoleide. The pigeon was used as the test animal—R LECOQ and J SAVARE *Bull sci pharmacol*, 42 (1935), 161 (C T I)

Chemical Constitution and Taste—Relations between In previous studies of the variations in taste attention was directed principally to modifications of the carbonyl and imide groups. The research reported in this paper followed the observation that the better known synthetic sweet compounds, such as saccharin and dulcin, are derivatives of ammonia in which one or more hydrogen atoms are substituted by negative radicals. The author studied the products derived from ammonia by substitution of an acyl radical for a hydrogen, *i e*, the acetyl radical and halogenated acyl radicals. The following compounds were prepared from aqueous or alcoholic ammonia and the ester acetamide, monobromoacetamide, monochloroacetamide, dibromoacetamide, dichloroacetamide, tribromoacetamide, trichloroacetamide, monoiodoacetamide. With the chlorides and the bromides the taste became more sweet with increase in number of halogen atoms introduced into the acyl radical, or as the radical becomes more negative. The pH values for 1% solutions of the dihalogen substituted compounds are higher than for the mono or trihalogenated compounds. The pH values are lower for those compounds of bitter or pungent taste—ANTONIO GIACOLONE *Gaz Chim Ital*, 65 (1935), 129-131 (ANNE E WHITE)

Cocaine Salts—Study of the Activity of Different A series of solutions of salts of cocaine containing in 100 cc the same quantity (0.892 Gm) of cocaine base or 1 Gm of cocaine-HCl was prepared and the reactions were regulated by means of the corresponding acids to pH 4. The solutions were assayed on the rabbit's cornea according to J RÉQUIER (*Bull sci pharmacol*, 30 (1923), 580-646). The following values represent the percentage concentrations of cocaine-HCl which are the anesthetic equivalents of the solutions studied: Citrate 0.2, lactate 0.4, tartrate 0.6, sulphate 0.8, phosphate 1.0, hydrochloride 1.0, hydriodide 1.2, sulphocyanate 1.5, formate 2.5, acetate 2.9, salicylate 4, benzoate 5, phenylacetate 12. These results do not follow the theory that only the liberated base is responsible for anesthetic action. The following conclusions are drawn: 1. The activities of the salts do not arrange themselves according to the degree of hydrolysis. 2. Certain acids (particularly citric) exhibit actions entirely unfavorable to the utilization of the alkaloid, the solution of cocaine citrate being almost totally unabsorbed by the rabbit cornea. 3. The solubility in cellular lipids is not the only factor as claimed by the Meyer and Overton theory, since the salts arrange themselves according to an order determined by Hofmeister on albuminoid substances—J RÉQUIER and R DAVID *J pharm chim*, 22 (1935), 16-22 (S W G)

Coffee and Decaffeinated Coffee—Effect of, upon Tremor in Normal Men and Women

Seven young men and an equal number of women received coffee on one day of each week for several weeks and decaffeinated coffee or no special beverages on the intervening days. With the hand in a static position and the forearm supported to the wrist, the vertical movements of the index finger were magnified by an optical lever and recorded photographically. The rate of the tremor remained approximately constant throughout the experimental period even when the different beverages were administered. The amplitude of the tremor was increased for several hours after a single dose of coffee, but was not changed by decaffeinated coffee. In the women coffee containing caffeine equivalent to 2 mg per Kg of body weight produced an increase in the amplitude of the tremor but in the majority of the men the effective dose was double this size — KATHRYN HORST and J R WILLSON *J Pharmacol*, 54 (1935), 147 (H B H)

Corydaline Hydrochloride—Action of, on the Isolated Small Intestine. Corydaline is the alkaloid from *Violeta Bulbosa* (*Corydalis cava*) and corresponds to the formula $C_{22}H_{21}O_4N$. It suppresses the peristalsis of the small intestine — PEDRO N SIVORI *Rev Centro Estud Farm Bioquim*, 25 (1935) 209 (A E M)

Curare and Its Constituents—Pharmacology and Therapeutics of. A full historical and geographical survey of what is known about curare. The author found one sample of curare which had what he termed a "lissive" action that is, the power to remove pathological rigidities without interfering with voluntary movement, thus he was able to relieve tetany in dogs after removing the parathyroids and to relieve chronic spastic disease in man. He has examined many specimens of different varieties of *Strychnos* in further search for the lissive action. The lissive action is not shown by the crystalline curarine chloride prepared by King — R WEST *Proc Roy Soc Med* 28 (1935) 565 through *Quart J Pharm Pharmacol*, 8 (1935), 305 (S W G)

Acetanilid—Ratio of Toxicity of, to Its Antipyretic Activity in Rats. In rats febrile by yeast injections a dose of 12.5 mg per Kg of acetanilid produces an average fall in temperature of $0.6^{\circ}C$, while smaller doses are without significant effect and larger doses produced greater effects. Twelve and one-half mg per Kg has been taken to be the minimal therapeutic dose for rats. In normal animals, 50 mg per Kg of acetanilid produces a significant decrease in temperature, similar to the fall produced in febrile animals by 12.5 mg per Kg. The lowering of the temperature of the normal animal may be considered an early undesirable effect. The dose fatal to 50% of the rats is 800 mg per Kg. A therapeutic ratio of 64:1 for the antipyretic effect of acetanilid in rats has been obtained — PAUL K SMITH and W E HAMBOURGER *J Pharmacol* 54 (1935) 346 (H B H)

Adhesive Plaster—Irritants in. Patch tests with 8 varieties of adhesive plaster manufactured by six companies were made on 120 subjects, the patches left on for 48 hours and the reactions read. Fifty patients showed a reaction to one or more of the adhesives with the least number of reactions for one adhesive 16% and the greatest number 25%. In addition there were 13 late reactions. Six out of the group which showed marked reactions at the first removal of the adhesive tape with continued intensification at the second inspection, were tested with South American Para rubber (I), starch (II), lanolin (III),orris root (IV), iodine rosin (V), olibanum (VI), gutta serena (VII), beeswax (VIII), Burgundy pitch (IX), zinc oxide (X) and wood rosin (XI). In this group there was sensitization to at least two of the ingredients of adhesive plaster. Six were sensitive to IX, 5 to I, 3 to XI, 2 to VI, 2 to VIII, and one each to III, IV and VII. In the group showing only a slight erythema at the first inspection but who developed delayed reactions tests were made on 12 persons. At the first inspection there were two reactions to V and 3 reactions to XI. Three patients who showed nothing more than erythema at the site of the patch were patched with the 11 ingredients but no positive reactions were obtained and none of the reactions lasted 72 hours. The authors conclude that skin reactions are due to traumatic phenomena or to hypersensitivity to one or more of the ingredients of the plaster. They suggest that non irritating types of resins and rubber should be substituted for the present types used — L SCHWARTZ and S M PECK *Pub Health Repts* 50 (1935), 811, through *Squibb Abstr Bull* 8 (1935), A 915

Alcoholism—Experimental Studies in. IV Attempts to Modify the Concentration of Alcohol in the Blood after Intravenous Administration of Alcohol. The influence of various substances and procedures (diathermy, epinephrine, insulin, caffeine, carbon dioxide, oxygen, olive oil, physiological salt solution and magnesium sulphate) upon the concentration of alcohol in the human blood stream after intravenous administration of alcohol was tested. The maintenance of an elevated body temperature by diathermy apparently caused an increased rate of disappearance

of alcohol from the blood, none of the other procedures tried had any effect that could be considered significant—ROBERT FLEMING and DOROTHY REYNOLDS *J Pharmacol*, 54 (1935), 236

(H B H)

Alkaloids—Distribution of, in Different Parts of Central Nervous System and their Quantitative Microdetermination in Tissues II Quinine and Mescaline Quinine (I) appeared and disappeared more rapidly in the portions of the nervous system rich in cells. The concentration of I in the blood was at first a little more and then somewhat less than in the brain, the concentration in the liver and kidneys was much the highest. I was extracted from the tissues and determined by the fluorescence in sulphuric acid solution. Mescaline (II) determined by sublimation, showed a similar distribution to I although a greater concentration of II in the spinal fluid was observed. Dogs and monkeys were used in the experiment—M VOGT *Arch expil Path Pharmacol*, 178 (1935), 560, through *Squibb Abstr Bull*, 8 (1935), A 969

Alkaloids—Distribution of, in Different Parts of Central Nervous System and Their Quantitative Microdetermination in Tissues I Scopolamine and Atropine A study of the distribution of scopolamine and atropine in various parts of the central nervous system, at various intervals following the administration to dogs and cats and in the presence of ether and morphine. The greatest amount of alkaloid was found in the portions rich in cells, particularly the cerebral cortex and the lowest amounts in the nerve fibers and spinal fluid. The liver and particularly the kidney contained more alkaloid than the cortex. The blood contained approximately the same amount of alkaloid as the brain. The alkaloids were determined by their mydriatic effect in mice. Data are given for the absorption on animal charcoal of the hydrochlorides of apomorphine, bulbo-capnine, quinine, strychnine, atropine, scopolamine and mescaline, from M/100 and M/1000 solutions thereof—F VEIT and M VOGT *Arch expil Path Pharmacol*, 178 (1935), 534, through *Squibb Abstr Bull*, 8 (1935), A 969

Allium—Contribution to the Determination of Preparations of Daily oral administration of 0.5 cc of garlic juice decreased or prevented calcification (sclerosis) and prolonged life from 12.9 to 30–50 days in mice fed high protein diets and 0.2–0.3 cc per day of irradiated ergosterol (Vigantol). Similar results were obtained with *Allium ursinum* L. (I). This property of the allium preparations may be used for their bioassay. The allium preparations had no oral toxicity. The press juice of fresh I had such low toxicity by intravenous injection that it was practically not detectable in the mouse—U HINTZELMANN *Arch expil Path Pharmacol*, 178 (1935), 480, through *Squibb Abstr Bull*, 8 (1935), A 948

Ascorbic Acid (Vitamin C)—Comparison of Oral and Subcutaneous Administration of Protective Doses of The minimal protective dose by mouth is twice as large as that by subcutaneous injection—H C HOU *Proc Soc Exptl Biol and Med*, 32 (1935), 1391

(A E M)

Bismuth-Lecithis—An Injectable Preparation of Lecithis a lecithin containing oily solution of bismuth tri-camphosphate has been investigated. Dogs and guinea pigs have been used in this work and results show it to be relatively rapidly absorbed. After one intramuscular injection in a dog, the elimination begins quickly and continues for weeks—GEORGE KINGISEPP and JUTA OLESK *Deut Med Wochschr*, 61 (1935), 997–1000

(H R)

Blood Alcohol Its Relation to Intoxication in Man In general, intoxication is not noticeable in the human until the blood alcohol concentration is greater than 0.2%, from 0.31 to 0.4% there is a marked intoxication, alcoholic stupor is definite between 0.41 and 0.5%, above 0.5% coma and death may result—R G TURNER *Proc Soc Exptl Biol Med*, 32 (1935), 1548

(A E M)

Bone Phosphatase—Activity of, in Chronic Fluorine Poisoning The effect of chronic fluorine poisoning upon bone phosphatase was studied by comparing the phosphatase activity of control rats at various ages prior to weaning with that of rats of the same age whose only source of fluorine was the milk of the mother rat on a diet containing fluorine. The number of rats in each litter was the same. The rats used for comparison were killed at the same age, and an extract of bone phosphatase from the hind legs prepared under identical conditions. Bone phosphatase activity for the control rats showed an increase with age from the time of birth to the age of thirty days, whereas that of the poisoned group showed a decrease from the time of birth, reaching a minimum at about fifteen days of age and returning to the normal for the control rats at thirty days of age. This decrease in bone phosphatase activity harmonizes with the obvious retardation of calci-

fication in the bones of young fluorine poisoned rats—JOHN O THOMAS, R H WILSON and FLOYD DE EDS *J Pharmacol*, 54 (1935), 160 (H B H)

Bulbocapnine—Ratio between Effective and Lethal Doses of, in the Cat. The minimal effective and minimal lethal doses of bulbocapnine vary markedly in the cat, in this series the former ranged from 2 to more than 4 mg per Kg, the latter from 70 (and less) to 130 mg per Kg. Body weight does not appear to be a factor responsible for this variation. The ratio between M E D and M L D ranged from an estimated low of 1.15 to 1.57 in this series. While most animals under lethal and sub lethal dosage showed strychnine-like convulsions predominately, several manifested these effects only transiently, and one not at all—R S AMADON and A H CRAIGE *J Pharmacol*, 54 (1935), 334 (H B H)

Digitalis—Relationship of Potency of, as Determined by Different Methods. Among the group of samples of digitalis leaf, two (D and F) were found to be equally effective by the usual Hatcher-method of slow intravenous infusion into the mammal (cat and dog). To cause the same mortality in groups of frogs after injection into the lymph-sac, however, there was required 40% more of leaf F than of leaf D, in the frog therefore leaf F was significantly weaker than leaf D. On the other hand, by clinical assay and by determinations of toxicity in experimental cumulative poisoning (dog), tinctures of leaf F were if anything, slightly more potent than tinctures of leaf D. In preliminary experiments the clinical assay-method was shown to be capable of distinguishing among tinctures of the relative strengths 75 100 125. In the cases of these two samples of digitalis leaf, therefore, assay in the mammal indicated potency more accurately than assay in the frog—R C LI and H B VAN DYKE *J Pharmacol*, 54 (1935), 151 (H B H)

Digitalis Lanata Ehrh.—Pharmacological Investigation on. The toxicity of the leaves of *Digitalis lanata* is distinctly greater (25%) than that of *Digitalis purpurea*. The toxicity of the powdered *Digitalis lanata* does not vary, even after a year of storage in an atmosphere of carbon dioxide. The leaves treated with chloroform and dried in a current of warm air are less active than those dried at ordinary temperature and without special treatment—A RABBENO and C MARINI *Boll Soc Ital Biol Sper*, 9 (1934), 748-750, through *Chimie et Industrie*, 33 (1935), 677 (W A P)

Dinitrophenol—Action of, on Rate of Oxidation of Ethyl Alcohol in Vitro. At a pH of 7.4 concentrations of dinitrophenol from 1-5,000,000 to 1-20,000,000 slightly increased the rate of oxidation of alcohol by rat liver *in vitro*, while higher concentrations slightly diminished it. This indicated that under some conditions an increase of tissue metabolism produced by dinitrophenol is accompanied by an increased rate of oxidation of alcohol—H W NEWMAN, W C CUTTING and M L TAINTER *Proc Soc Exptl Biol Med*, 32 (1935), 1479 (A E M)

Drugs—Absorption of, Through the Oral Mucosa. II. The ratio of sublingual to similarly effective subcutaneous doses was determined as follows: Cocaine 2, diacetylmorphine 3, thebaine greater than 4, emetine greater than 6—ROBERT P WALTON *Proc Soc Exptl Biol Med*, 32 (1935), 1486 (A E M)

Drugs—Absorption of, Through the Oral Mucosa. III. Fat-Water Solubility Coefficient of Alkaloids. The oil-water solubility coefficient is an important factor in the selective oral absorption of alkaloids. Other factors which are significant are relative potency, degree of local vasoconstriction, irritation and alkalinity or acidity—ROBERT P WALTON *Proc Soc Exptl Biol Med*, 32 (1935), 1488 (A E M)

Drugs—Distribution of, in Different Parts of Central Nervous System and Their Quantitative Microdetermination in Tissues. VI. Chloral Hydrate. Data are given on the distribution of chloral hydrate (I) in various parts of the nervous systems of cats and dogs, at various intervals after administration. I was extracted from the tissues with ether and the ether residue taken up in dilute sulphuric acid. I was determined by reduction with zinc dust in acetic acid solution and titration of the chlorine according to the Volhard method. I appeared and disappeared more rapidly from the portions rich in cells. Maximum concentration was reached in a few minutes in all parts—M VOGT *Arch exptl Path Pharmacol*, 178 (1935), 628, through *Squibb Abstr Bull*, 8 (1935) A-969

Ephedrine—Observations on Dogs under Continued Influence of. Remarkable constancy is found in the systolic blood pressure of dogs in standard conditions. Ephedrine produces a disturbance of nitrogen metabolism, probably by diminishing the assimilation of protein. A transient diuresis is always observed. Glycosuria usually persists after withdrawal. Tolerance to the

pressor action of ephedrine is manifested. Ephedrine administration in doses that maintain a continuous hypertension may be continued for 2 weeks without other effects, the blood pressure and protein absorption return to normal within a few days of withdrawal —ERIC OGDEN and A R TEATHER *J Pharmacol*, 54 (1935), 320 (H B H)

Ergoclavine—Action of, on Diuresis Ergoclavine is a new alkaloid obtained from ergot of rye and has pharmacological action similar to that of ergotamine and ergotamine. With respect to its action on diuresis, ergoclavine in doses of 0.0075–0.04 mg per Kg intramuscularly diminished considerably the amount of fasting urine in dogs, and also inhibited the diuresis following the ingestion of water or sodium chloride solution, but to a smaller extent than did the injection of 0.15–0.2 mg of ergotamine. Unlike the latter compound, ergoclavine did not decrease diuresis caused by a urea solution, but rather increased it —E ZUNZ and O VESSELOVSKY *Compt rend soc biol*, 119 (1935), 534, through *Squibb Abstr Bull*, 8 (1935), A 925

Ergoclavine and Sensibamine—Action of The author concludes that the new ergot alkaloids, ergoclavine and sensibilamine, produce pharmacological effects identical in character and intensity with those of ergotamine, and therefore with those of ergotamine also. These comparative studies were made upon the isolated guinea pig and rabbit uterus as well as upon the "vasomotor reversal" preparation of the cat —A VARTIAINEN *J Pharmacol*, 54 (1935), 259 (H B H)

Ethyl Alcohol—Effect of Certain Drugs on the Metabolism of Alcohol was administered to dogs by stomach tube in doses of 15 or 30 Gm per Kg and determinations of blood alcohol made over a period of twelve hours. The normal blood alcohol curve was not changed by the administration of one unit of insulin per Kg, either when the insulin was given alone or with sufficient glucose to prevent a drop of blood sugar. Large doses of thyroxine or desiccated thyroid administered some days prior to the alcohol experiment caused very little change, if any, from the normal curve. On the other hand the disappearance of body alcohol was greatly accelerated by the administration of dinitrophenol in a dose of 7.5 or 15 mg per Kg, the rate of alcohol consumption by the tissues being about doubled in some cases. Dinitroresol in a dose of 7.5 mg per Kg produced about the same results as did twice this dose of dinitrophenol. Determinations of the loss of alcohol by breath showed that only a small part of the effect produced by the dinitro compounds was due to increased excretion by the lungs. The doses of the dinitro compounds necessary to cause much acceleration in body oxidation of alcohol are probably too toxic for them to be of any practical use in the treatment of acute alcoholism and the results are presented solely for their scientific value —R N HARGER and H R HULPIEU *J Pharmacol*, 54 (1935), 145 (H B H)

Lanadigin, Digitoxin and Ouabain—Cumulative Poisoning by Lanadigin (or digilandid C) has been considered, by clinical test, to be a relatively non-cumulative glucoside. It was compared with U S P ouabain and digitoxin by assay in the frog and dog and found to be of the same toxicity as digitoxin in the dog but about twice as toxic as digitoxin in the frog. In cumulation experiments in dogs, lanadigin proved clearly to be a more powerful cumulative poison than either ouabain or digitoxin —H B VAN DYKE and R C LI *J Pharmacol*, 54 (1935), 161 (H B H)

Local Anesthetics—Relation of pH and Surface Tension to Activity of The authors report observations upon the relation between surface tension and physiological activity for ten local anesthetics at varying known hydrogen ion concentrations. The following substances were studied: B-4-morpholine ethyl benzoate hydrochloride, B-4-morpholine ethyl cinnamate hydrochloride, B-4-morpholine ethyl phenylurethane hydrochloride, B-4-morpholine ethyl α -naphthylurethane hydrochloride, G-4-morpholinepropyl benzoate hydrochloride, G-4-morpholinepropyl cinnamate hydrochloride, G-4-morpholinepropyl phenylurethane hydrochloride, G-4-morpholinepropyl α -naphthylurethane hydrochloride, cocaine and procaine. Both surface tension lowering and anesthetic activity vary with the pH in a manner paralleling the titration curves, indicating that both effects can be attributed only to the base. No correlation between surface tension lowering by the individual compounds and their physiological activity could be detected —JOHN H GARDNER and JOSEPH SEMB *J Pharmacol* 54 (1935), 309 (H B H)

Luteal Hormone—Biological Study and Testing of The horns of the rabbit uterus at time of puberty appear small, very slightly vascular and slightly muscular. Only a very small amount of blood vessels are visible, and the epithelium is simple. Injection of luteal hormone alone pro-

duces no change. If some follicular substance is included, there is an increase in diameter in the horns of the uterus, the muscular appearance changes and the secretion is altered. Further injection causes intense reactions, the horns become extremely large, moist and congested, the muscular layer disappears and blood vessels appear in the form of a network. These vessels are dilated. The determination is carried out as follows. Inject subcutaneously into a 600-800 Gm Parisienne rabbit, at time of puberty, during 6 consecutive days, 4 mg per day of crystalline follicular substance contained in an oil solution. Also inject subcutaneously during the next 6 days the substance to be studied, in an oil solution. At the end of the twelfth day the animal is killed, the uterus removed and placed in formaldehyde solution. An examination in an Ultrapak is immediately carried out. Standard unit setup is the amount of luteal substance which corresponds to the physiological activity obtained by injection into an 800 Gm rabbit at age of puberty, after subcutaneous administration of follicular substance, of 0.2 mg of crystalline luteal hormone prepared in oil solution and injected during 6 consecutive days.—H. PENAU and H. SMONNET, *J. pharm. chim.*, 21 (1935), 485 (M. M. Z.)

Male Hormone—Biological Estimation of, upon the Hardhead. A critique of the two currently used methods of standardization supplemented with a report of an improvement in the castration technique of Glaser and Haempel. B's technique consists in anesthetizing the fish with urethane or soneryl and then making as short a ventral incision as is possible with the aid of fine scissors at the area of the genital buds. The gonads are exposed carefully with the aid of surgical forceps, and then removed. The operative area is dried with absorbent cotton or surgical gauze, 'painted' with ether and sealed with collodion. The per cent recoveries by this technique, on two lots, were 89 and 100 respectively, as compared with the approximate 50% recoveries obtained with the straight G and H technique. B finds the intramuscular route the best method of giving the orchic extracts to the test objects. In no instance, did a non active extract, as determined on castrated test objects, prove to be active when intact fish were used. Careful temperature control and utilization of as large a number of fish as is practical are of paramount importance for accurate work.—A. BEAUNE, *Bull. sci. pharmacol.*, 42 (1935), 193 (C. T. I.)

Mannide and Isomannide—Fate of, in the Animal Body. The chemistry of mannitol, isomannide and mannide is reviewed briefly and the structural formulae are given. The results are summarized as follows: 1. The removal of 2 molecules of water from 1 molecule of mannitol with the formation of isomannide or mannide destroys the capacity of mannitol to be stored as glycogen in the liver of the white rat. 2. Mannide significantly increases the respiratory quotients of white rats, while isomannide does not. 3. Isomannide and mannide are ineffective in relieving insulin shock in mice and are also incapable of raising the fasting blood sugar level of rabbits.—J. C. KRANTZ, JR., W. E. EVANS, JR. and C. J. CARR, *Quart. J. Pharm. Pharmacol.* 8 (1935), 213-217 (S. W. G.)

Methylamino-methyl Heptene—Pharmacological Action of. This compound has the formula

It is a sympathetico mimetic-amine which stimulates the respiratory center and to a lesser degree other parts of the central nervous system. It relaxes those smooth muscles which have an inhibitory innervation from the true sympathetic the stomach, intestine, etc., but it dilates the pupil, stimulates the heart and will sometimes restore a heart with fibrillating auricles to a normal beat. With correct dosage and under suitable conditions the drug is capable of producing a great rise of arterial pressure which may not come down to normal for two or three hours. On intravenous injection of the drug the volume of the kidney, spleen, etc., shrinks, the stomach relaxes, the mucosa of the nose and pharynx shrinks greatly and the bronchioles dilate. The drug has a trade name 'octin,' is markedly slower in action than epinephrine, and will have a very considerable clinical use.—D. E. JACKSON, *J. Pharmacol.*, 54 (1935), 152 (H. B. H.)

Morphine—Action of, as a Metabolic Stimulant. Fifty-one successful experiments were made upon four dogs studied systematically at the fourth, eighth, sixteenth and twenty fourth hour after the daily injection. The average metabolic increases for the entire twenty four hours were

found very significant, being respectively 11.2, 7.3, 4.8 and 14.8%. The authors emphasize the importance of maintaining the adult animals at constant body weight and upon a practically perfect state of rest during the tests which were made in a copper chamber with closed Benedict Universal Apparatus—H. G. BARBOUR and JANET ANDREWS *J Pharmacol*, 54 (1935), 137

(H. B. H.)

Morphine, Codeine, Heroin and Dilaudid—Comparative Study of Analgesia Produced in Normal Subjects by The table gives the average results from five subjects, selected for their analgesic response, to whom various doses of the four drugs were administered subcutaneously at weekly intervals. Five sensitive face spots as determined with von Frey hairs were employed to measure the degree of analgesia. Neither the subject nor the observer had knowledge of the drug or dosage used.

	Dose Required to Give Equal Peaks of Analgesia Mg	Peak of Analgesia Reached Minutes	Duration of Analgesia Minutes	Subjective Degree of Depression	Subjective Degree of Euphoria
Morphine sulphate	8	90	200	5	1
Codeine phosphate	64	30	150	1	0
Heroin hydrochloride	1-1.5	30	130	2	4
Dilaudid hydrochloride	0.8	90	165	3	1

No definite correlation can be made between the subjective sensation of depression and the actual analgesia obtained. In confirmation of Mullin and Luckhardt it is noted that hyperalgesia often follows the period of analgesia even though the individual is still subjectively depressed at the time. A most constant and striking finding is the difference in time required after administration for the various drugs to produce their maximum analgesic action. Although solubility is not the only factor involved, rapid onset of analgesia does occur with the most soluble salts—C. C. PFIEFFER and M. H. SEEVERS *J Pharmacol*, 54 (1935), 156

(H. B. H.)

Nicotine—Contribution to Pharmacology of This study was made to determine the nature of the nicotine action causing failure of respiration in cats. Application of fairly large doses of nicotine to the floor of the fourth ventricle failed to paralyze respiration. The minimal lethal dose by intravenous injection was found to be consistently smaller than by intracarotid injection. Following the administration of the minimal lethal dose stimulation of the phrenic nerve and of the diaphragm directly showed that the myoneural junctions had been completely, or almost completely paralyzed. A record of phrenic nerve potentials showed that when the muscles of respiration had ceased to function as a result of nicotine the intermittent discharges from the respiratory center continued as in the normal. From the above evidence the authors conclude that nicotine causes respiratory failure as a result of a curare-like peripheral paralysis—HARRI GOLD and FREDERICK BROWN *J Pharmacol*, 54 (1935), 143

(H. B. H.)

Parathyroid Hormone—Use of Rabbits in the Standardization of The blood serum of rabbits has been found to respond to injections of parathyroid extract given together with oral administrations of calcium chloride. The variations in the calcium concentrations in the serum of rabbits was found to be of a qualitative rather than a quantitative nature. The method of Hamilton and Schwartz (*J Pharmacol*, 46 (1932), 285) or its modification by the author may be used to detect, but not to measure small quantities of parathyroid hormone. The results of the experiments are given in tables and plotted curves—F. J. DYER *Quart J Pharm Pharmacol*, 8 (1935), 197-212

(S. W. G.)

Phenobarbital—Effects of Phenacetin and Aspirin, Respectively, upon Action of Whereas acetylsalicylic acid antagonizes the hypnotic action of phenobarbital, phenacetin in no way diminishes its activity. Phenacetin may exert a protective influence by antagonizing the toxic effects of phenobarbital—ALFRED GILMAN and HENRY G. BARBOUR *Proc Soc Exptl Biol Med*, 32 (1935), 1634

(A. E. M.)

Pituitary Extract—Hypersensitiveness to A case report in which a 28-year old housewife, without personal or family history of allergic diseases, exhibited a severe hypersensitivity to a dose of pituitary extract at the birth of her seventh child. Massive swelling of the lips and face was noted and the patient complained of a swollen tongue. She began to have difficulty in breathing, which was evidently due to obstruction in the upper respiratory tract. The edema of the larynx

increased rapidly and she had more respiratory difficulty. The administration of epinephrine relieved the situation and she recovered completely. Subsequent skin tests showed positive reactions to cattle, hog and human pituitary extracts, but negative reactions to cerebral cortex and skeletal muscle extracts of cattle, hogs or humans—F. A. SIMON *J. Am. Med. Assoc.* 104 (1935), 996 (M. R. THOMPSON)

Potassium Salts—Diuretic Action of Doses of from 0.1 to 0.2 Gm. per Kg. daily for several days of potassium chloride, nitrate, bicarbonate, acetate and citrate were given by mouth to normal individuals and patients having edema, in some of the latter, kidney disease was present. These salts lead to the increase of excretion of water and potassium in the urine, the most regular and sustained diuresis occurred with the nitrate. The kidney was able to concentrate the potassium of the serum approximately fifty times. When this concentrating function is preserved in renal disease, potassium salts seem to be well tolerated—NORMAN M. KEITH and MELVIN W. BINGER *J. Pharmacol.*, 54 (1935), 148 (H. B. H.)

Pukateine—Pharmacological Action of The alkaloid, pukateine can be extracted from the bark of the Pukatea tree (*Laurelia Novae Zeelandiae*, Monimiaceae). It has the formula $C_{18}H_{17}O_3N$, and the constitution has been established by Barger and Girardet. In the form of the hydrochloride pukateine has the following minimal lethal doses in terms of grams per kilogram body weight: frog, 0.25 (anterior lymph sac), mouse, 0.18 (subcutaneously), rabbit 0.12 (intravenously) and 0.2 (subcutaneously). It tends to depress all muscle tissue with the possible exception of the uterus. It depresses conductivity of the nerves. The action upon the central nervous system is similar to that of morphine, the depressive effect being most marked upon the respiratory center. It produces a peripheral vaso-dilatation and this in conjunction of the diminished cardiac output produces a fallen blood pressure. The effect on the refractory period and the ability to prevent cardiac fibrillation is also described—WILLIAM S. FOGG *J. Pharmacol.*, 54 (1935), 167 (H. B. H.)

Pyrethrins—Action of, on Marine Animals A pharmacodynamic study of the neuromuscular toxic activity of pyrethrins. The tests were carried out (1) by placing the test object in dilute emulsions of the pyrethrins, thereby allowing the animal to absorb the toxic agents by the respiratory tract, and (2) by administering the pyrethrins hypodermically. In each instance control tests were carried out to ascertain the effect of the dilutions of alcohol present in the emulsions. The pyrethrins are more active upon fish, crustacea and cephalopod molluscs when the toxic agents are taken up by the respiratory tract. Fish are also very sensitive to hypodermic doses. The echinoderms are practically unaffected by pyrethrins when administered by either of the above routes—O. GAUDIN *Bull. sci. pharmacol.* 42 (1935), 145, 222 (C. T. I.)

Retrorsine—Action and Toxicity of Retrorsine, an alkaloid of *Senecio retrorsus*, in the form of a hydrochloride induces weakness and paralysis of the extremities of frogs in the dosage of 1 mg. per Gm. In white mice it causes acute death within two and one half hours with clonic convulsions in the dosage of 290 or more mg. per Kg., injected intravenously. Doses of 70 to 145 mg. per Kg., produce no convulsions but hepatic necrosis and renal degeneration in the majority of animals, and finally death in one to eight days. In guinea pigs, the minimal lethal dose of retrorsine hydrochloride by intravenous injection is approximately 320 mg. per Kg. An amount equivalent to 50% of the minimal lethal dose, repeated every other day for four doses failed to bring about any visceral changes in ten days. The guinea pig is apparently less susceptible than the mouse to this alkaloid. Retrorsine has a depressor and a hyperglycemic action. It inhibits isolated rabbits' intestines, but contracts isolated guinea pigs' virgin uteri—K. K. CHEN, A. LING CHEN and CHARLES L. ROSE *J. Pharmacol.*, 54 (1935), 299 (H. B. H.)

Sedatives and Hypnotics The author discusses the physiology of the nervous system briefly and mentions some of the desirable qualities in medicaments. He describes the pharmacological action of the various classes of sedatives and hypnotics such as chloral, paraldehyde, the barbitol derivatives, bromides, cocaine, organic bromine compounds, scopalamine and others—ALFRED FRÖHLICH *Scientia Pharm.*, 6 (1935), 57 (M. F. W. D.)

Sodium Propyl-Methyl-Carbinyl-Allyl Barbiturate A Short-Acting Hypnotic. The drug was compared with pentobarbital sodium and amytal. Oral administration causes earlier appearance of ataxia. The duration of anesthesia was longer than with pentobarbital and about the same as with amytal. However, the time of recovery was only half that of sodium amytal—EDWARD E. SWANSON *Proc. Soc. Exptl. Biol. Med.*, 32 (1935), 1563 (A. F. M.)

Sodium Thioethanesulphonate—Metallic Derivatives of, in Therapeutics Organometallic compounds containing the —SH group in which H is replaced by gold, bismuth, antimony, mercury and other heavy metals, were prepared by the following series of reactions $\text{CH}_3\text{Br} \cdot \text{CH}_3\text{Br} + \text{Na}_2\text{SO}_3 = \text{CH}_3\text{BrCHSO}_3\text{Na} + \text{NaBr}$, $\text{CH}_3\text{BrCHSO}_3\text{Na} + \text{NaHS} = \text{HSCH}_3\text{CHSO}_3\text{Na} + \text{NaBr}$, treatment of the mercaptan with gold chloride gives $\text{AuSCH}_3\text{CHSO}_3\text{Na}$, amorphous, very light yellow containing 53% gold (theoretical 54.7%), remains unchanged when heated to 170°, above 170° gradually turns yellow and becomes light brown at 280°, easily soluble in water to a barely perceptible yellow, insoluble in oil and in all organic solvents, unaffected by the usual reagents for gold (except hydrogen sulphide which produces first a brown coloration and finally a precipitate of sulphide, stannous chloride in hydrochloric acid solution and nitric acid destroy the complex with precipitation of gold). A 5% solution, when injected subcutaneously or intramuscularly, is easily absorbed, it produces no shock phenomenon when injected intravenously. In spite of its high gold content, it is a little less toxic than most of the other gold thioderivatives (about 0.05 Gm. per kilo body weight), with the exception of the metallic thioderivatives of sugars, but the lower toxicity of the latter is accompanied by a correspondingly low activity.—AUGUST LUMIERE and FÉLIX PERRIN *14me Congrès de Chimie Industrielle, Paris*, Oct. 21-27, 1934 (A P-C) 3 pp

Spinal Anesthesia in the Rabbit Therapeutic Coefficients The minimal lethal dose as well as the minimal anesthetic dose by subarachnoidal injection was established for several anesthetics upon rabbits. From these two threshold concentrations the therapeutic coefficients for these anesthetics can be calculated as follows: metycaine, 4.0; procaine, 6.6; panthesine, 8.0; nupercaine, 11.4; tutocaine, 12.0; and pantocaine, 30.0.—R. N. BIETER, R. W. CUNNINGHAM, O. LENZ and J. W. McNEARNEY *J Pharmacol* 54 (1935) 137 (H B H)

Syntropan—Contribution to the Pharmacology of The results of the various tests carried out, together with reproductions of kymograph tracings, are presented. The following conclusions have been drawn: 1. Syntropan has in 1 d 11 Gm. per Kg. of body weight of toad intralymphatically in 18 hours and 316 mg. per Kg. of body weight of rabbit hypodermically in 40 minutes. Post mortem examination revealed no organic lesions. The heart was arrested in diastole with venous congestion. 2. In the toad and rabbit, syntropan in small doses stimulates the cerebrum and, if the dose is high, convulsions occur, which are central in origin. In fatal doses the drug paralyzes the cerebrum and the respiratory center. 3. In stronger solutions, syntropan acts like atropine in antagonizing the effect of arecoline hydrochloride on heart, intestine and ureter. 4. In the dog, syntropan in moderate doses lowers the blood pressure in spite of the acceleration of heart beat and vasoconstriction. The drug depresses the cardiac muscle directly. Syntropan stimulates the respiratory center in small doses. 5. There is no evidence that syntropan is a valuable drug for the relaxation of plain muscle tissue. In fact the uterus and mesenteric vein respond to the drug by a rise of tone. 6. The drug has practically no action on the gastrocnemius muscle of the toad in a 1:1000 solution. 7. The dilatation of the pupil of the rabbit produced by strong solutions of syntropan is inferior to that produced by atropine in more dilute solutions.—KARAM SAMAN and MOHAMED I. EL ASREGY *Quart J Pharm Pharmacol*, 8 (1935), 186-196 (S W G)

Thyroid—Pharmacology of, in Man A review, with discussion, of the effects produced by thyroid, thyroxine and certain compounds structurally related to thyroxine upon clinical patients. The iodine content of desiccated thyroid, with its relationship to calorogenic activity receives interesting consideration. It has been calculated that in a normal man the thyroid forms thyroxine or its equivalent at the rate of about 0.3 mg. a day and that there are about from 10 to 14 mg. in the body outside of the thyroid gland. Following the intravenous administration of a single dose of 10 mg. of thyroxine to a patient with myxedema, there is a marked lag in the clinical improvement behind changes in the metabolic rate, the period of highest metabolism being characterized by intoxication and the period of falling metabolism by improvement. Observations on the calorogenic action of diiodotyrosine, thyronine, diiodothyronine and N acetyl thyroxine show that the amino group, the diphenyl ether group and all four iodine atoms are essential for the maximum effect of thyroxine. Of special interest is the rather rapid return of the metabolism to the level before treatment following a single dose of diiodothyronine (from seven to eight days respectively in two patients with rates of minus 35% and minus 40%) compared with the slow return following a single dose of thyroxine (from seventy to eighty days at a level of minus 40%). The increase

in metabolism produced by dinitrophenol in myxedema, with little or no clinical improvement, suggests that there may be different types of altered metabolism that cannot be differentiated by changes in the rate of oxidation alone. As the complexity of the molecule of various thyroxine compounds increases, the greater will be their absorption from the gastro-intestinal tract and hence the less the effect of alkali in augmenting the absorption. As a result of digestion with pepsin, data have been obtained which suggest that nearly all the calorogenic activity of the whole gland is possessed by less than half of the total iodine (acid-insoluble precipitate). The acid-soluble portion does possess slight calorogenic activity and after a single large dose the metabolism appears to return to its level before treatment more rapidly than after an equal change produced by the acid-insoluble precipitate. This finding has an important bearing on the U. S. Pharmacopoeia method of standardizing desiccated thyroid by a determination of the total organic iodine. After heating with approximately normal sodium hydroxide for four hours, desiccated thyroid loses more than two-thirds of its calorogenic activity, whereas thyroxine is unaffected by the same treatment. This finding has an important bearing on the proposed standardization of desiccated thyroid by a determination of its thyroxine content. The subcutaneous administration of extracts of the anterior lobe of the pituitary produced an increase in basal metabolism in eighteen of twenty-eight patients of various types including two with hypopituitarism, ten with low basal metabolism of unknown cause, several with nontoxic goiters, including three patients with mild myxedema, and one case of exophthalmic goiter. During the injections in the patient with exophthalmic goiter, a mild case of the disease became a moderately severe one.—W. O. THOMPSON, *et al.* *J. Am. Med. Assoc.*, 104 (1935), 972 (M. R. THOMPSON)

Trichlorethylene—Contribution to Pharmacology of Trichlorethylene in amounts of 0.12 cc per 100 Gm. of rat subcutaneously did not influence oxygen consumption. In perfused amphibian heart it had solely a depressant effect. When administered by inhalation to etherized dogs, it produced a fall in blood pressure and tended to diminish the rate and increase the depth of respiration. The influence of the drug on the coronary flow (Moravitz preparation) was irregular, in some cases it produced a decrease and in others an increase in the rate of flow. The authors are of the opinion that the drug exerts no specific influence on the coronary circulation. The relief afforded by trichlorethylene in certain cases of angina pectoris might be accounted for on the basis of its sedative action.—J. C. KRANTZ, JR., C. J. CARR, RUTH MUSSEY and W. G. HARNE. *J. Pharmacol.*, 54 (1935), 327 (H. B. H.)

Ureas—Relative Anesthetic Effects of Various. Hypnosis has been found to be a property quite common to the ureas. With respect to hypnotic effectiveness, in the alkyl ureas molecular weight is a determining factor, as with the aliphatic alcohols. In general, in the aliphatic ureas the hypnotic potency decreases in the following order, monoalkyl ureas, symmetrical dialkyl ureas (methyl series), unsymmetrical dialkyl ureas, symmetrical dialkyl ureas (ethyl series) and trialkyl ureas. The toxicity values are not consistent, thus making generalization concerning this property difficult. In the aryl and alkylaryl ureas molecular weight is not an important factor in determining hypnotic effectiveness. In these series, the position of a substituent group in position isomers is more important.—J. S. BUCK, A. M. HJORT and E. J. DE BEER. *J. Pharmacol.*, 54 (1935), 188 (H. B. H.)

Vitamin B—Studies of Crystalline. IV. Injection Method of Assay. A modification of the Smith injection technique for vitamin B assay is described which is quick, convenient and reasonably accurate. The material to be tested is injected from a tuberculin syringe through a 26 gauge needle into the fleshy part of the rat's hind leg. As much as 0.75 cc. of the liquid (pH 4.0-6.0) containing as high as 10% solids can be introduced into each leg subcutaneously with satisfactory results. The effect can be noted within 12-48 hours. With an adequate dose the symptoms of paralysis disappear entirely with an accompanying gain in weight. If the dose is very inadequate, the symptoms are not alleviated and may become definitely worse and there is generally a loss in weight. If the injected dose is barely adequate, a partial cure may result. With minimum curative doses paralysis recurs in 5-10 days after successful treatment. As a result of an extremely large dose animals have remained cured for as long as 32 days. Surviving animals that are not cured by the first injection are used again after the lapse of one day. Those that are cured or definitely improved are kept on the depletion diet until paralysis recurs and are then re-injected. In this way, the same rat can be used several times. The curative dose according to the response standard established is 5γ. The minimum dose which completely cures practically every animal

is 75γ—M AMMERMAN and R E WATERMAN *J Nutrition*, 10 (1935), 25, through *Squabb Abstr Bull*, 8 (1935), A-1019

TOXICOLOGY

Amidopyrine—Toxic Reactions of Therapeutic doses of amidopyrine, e g, 0.2–0.648 Gm, can exert a harmful effect on the general condition of sensitive persons (fever, chill, nausea, headache, etc) and on the activity of blood forming organs. The effect on the granulocytopoietic apparatus is stimulating as well as inhibitive, decrease in the total granulocyte value and increase in the immature and young elements. In individual cases, there is a subsequent leukocytosis. The amidopyrine effect extends to the monocyte- and lymphocyte producing organs and also to erythropoiesis. These changes recede spontaneously when the drug is discontinued, otherwise it is to be expected that the initial symptoms advance to a marked granulocytopenia with typical clinical manifestations. Three cases described by Bonsdorff, of which two were fatal, illustrate this. It is of utmost significance whether other antipyretics are capable of producing granulocytopenia. Antipyrine, the parent substance of amidopyrine and its derivatives, fall in this group. Several cases of granulocytopenia have already been reported with antipyrine. Salicylic acid has not yet been found to be an offending substance in humans, but it has been observed to cause granulocytopenia in animals. Barbituric acid preparations are dangerous because they are often combined with amidopyrine. Indeed one of the acids, 5 ethyl 5 phenyl barbituric acid (Luminal) has been reported as causing a decrease in the granulocytic value in animals.—B v BONSORFF *Klin Wochschr*, 14 (1935), 465, through *Squabb Abstr Bull*, 8 (1935), A-563

Arsine—Poisoning by A detailed description of a case in which an accidental fatal poisoning was traced to arsine from the circumstances accompanying the accident and the clinical symptoms, in spite of the fact that no arsenic was found in the analysis of the viscera. Death occurred 8 days after the victim had cleaned out the sludge from a tank 1 m high by 2 m in diameter, used for the purification of pyrites burner gases, the work having required only about 10 min. The sludge consisted of 13% iron sulphate, 84% lead sulphate and 2.6% arsenious oxide, instead of wooden tools, as usual, the victim had used an iron scraper which showed distinct signs of attack by acid. It was concluded that, in spite of the preliminary washing with water, there remained sufficient acid in the sludge to react with the scraper, with evolution of hydrogen which reacted with the arsenious oxide to form arsine.—J LECLERCQ and H SPRIET *Ann Med Légale Criminol Police Sci*, 15 (1935), 362–366 (A P-C)

Arsphenamine—Ocular Reactions Due to In twenty cases of primary and secondary syphilis (19 had early syphilis) treatment with arsphenamine produced toxic ocular reactions of varying degree. The initial signs were usually subjective and unilateral and frequently so slight as to produce no detectable eye changes, usually, however, there was slight haziness of the vitreous or blurring of the nerve head. Continuation of arsphenamine aggravated the condition producing considerable optic neuritis and possibly secondary optic atrophy. Vision improved fairly rapidly and returned to normal if the arsphenamine was discontinued when the first symptoms were observed. Further antisyphilitic treatment with iodides, bismuth or mercury caused no ocular symptoms and did not prevent the return of the eye condition to normal. Subsequent treatment with arsphenamine was possible in most cases if given cautiously with cessation at the first signs of ocular symptoms, but some cases showed hypersensitivity to the drug. Of the twenty cases with ocular symptoms, nine showed other arsphenamine reactions including nitrotoxic reactions, dermatitis and postarsphenamine hepatitis with jaundice. None of the cases showed any signs of neurosyphilis.—J J SKIRBALL and F M THURMON *Am J Syphilis & Neurol*, 19 (1935), 197, through *Squabb Abstr Bull*, 8 (1935), A-644

Atropine—Action of, on Reanimation of Heart in Secondary Chloroform Syncope The author points out that reported differences in the action of atropine in the heart in chloroform poisoning have been due to differences in the mode of injection. The author has injected atropine directly into the heart successfully, in contrast to results reported following injections into the jugular vein.—L GARRELON *Compt rend soc biol*, 118 (1935), 854, through *Squabb Abstr Bull*, 8 (1935), A-646

Aurotherapy—Dangers in Therapeutic use of gold may cause modifications in the blood (eosinophilia and agranulocytosis). The symptoms which are associated with true saturation (coated tongue, nausea, diarrhea) resemble the picture obtained in the case of uremia, in fact, in

these cases, amounts of urea as high as 50-60 cg have been found. It is well to detect these slight azotemias, since they are forerunners of polynucleosis and therefore of saturation. Regular ex amination of the constituents of the blood should be carried out during gold therapy.—R DUVAL *Bruxelles-Med*, No 23 (1935), through *J pharm Belg*, 17 (1935), 472 (S W G)

Benzene—Experimental Research on the Toxicity of the Vapors of Concentration of Benzene in the Blood and Speed of Removal A study of guinea pigs, weighing 800-850 Gm and subjected to benzene vapors, showed that the benzene content of the animal, especially with higher concentrations (20-50 mg /liter) is a linear function of the duration of inhalation, up to 20 minutes. The most severe symptoms are noticeable when the benzene content of the blood is 2.6-2.8 mg per 100 Gm of animal. Benzene vapors introduced into the animal by inhalation disappear quickly from the blood, when air is free from vapors, and the symptoms vanish. The vapors are eliminated chiefly by the lungs and partly by the kidney.—MARCEL PERONNET *J pharm chim*, 21 (1935) 503 (M M Z)

Bichloride of Mercury—Quantitative Study of Renal Injury in a Case of Acute Poisoning by A quantitative study of a case of acute mercuric chloride poisoning showed that extensive renal damage occurred almost immediately, lasted for several weeks and then improved slowly with return to normal function three and one half months after poisoning.—R H FREYBERG and F H LASHMET *Am J Med Sci*, 189 (1935), 392 through *Squabb Abstr Bull*, 8 (1935), A 589

Bromides—Toxic Reactions of A report of five cases of bromide intoxication observed in general medical practice. The recommended treatment is sodium chloride orally (6-8 Gm daily), by hypodermoclysis or intravenously.—E H HASHINGER and C C UNDERWOOD *J Kansas Med Soc*, 36 (1935) 183, through *Squabb Abstr Bull*, 8 (1935), A-752

Carbon Monoxide Poisoning—Chronic Effects on persons exposed to carbon monoxide for many years show that occurrence of chronic carbon monoxide poisoning cannot be doubted. Carbon monoxide haemoglobin is dissociated through abundant ventilation but this does not take place completely. A residue of carbon monoxide haemoglobin always remains.—HERMAN GERBIS *Deut Med Wochschr*, 61 (1935) 991-994 (H R)

Datura Stramonium—Food Poisoning from The authors describe an epidemic of food poisoning in Amsterdam involving at least 34 cases. The epidemic was caused by a grocery firm supplying a preserving factory leaves of *Datura Stramonium* in error, for savory.—H PEETERS and J C DE JONG *Pharm Weekblad*, 72 (1935) 715 (E H W)

α -Dinitrophenol—Chronic Lesions Produced by When administered to guinea pigs in amounts approximating the human therapeutic dose, α dinitrophenol produced hepatic lesions giving no external symptoms and shown to be due to the nitro groups.—R JONNARD *Ann Méd Legale Criminol Police Sci* 15 (1935), 181-183 (A P C)

Mercurial Diuretics—Reaction at Site of Injection of, as Influenced by Theophylline It has been demonstrated in animals and in man that the presence of theophylline in combination with a mercurial diuretic definitely decreases the local toxic reaction.—ARTHUR C DEGRAFF and ROBERT C BATTERMAN *Proc Soc Exptl Biol Med* 32 (1935), 1546 (A E M)

Methylene Blue, Methemoglobin and Cyanide Poisoning Methemoglobin does not accumulate in significant quantities in the blood of dogs after intravenous injection of clinically recommended quantities of methylene blue. This fact, however, should not bring into question the proposed methemoglobin explanation of the dye's action in cyanide poisoning. The failure of methemoglobin to accumulate is explicable on the basis of the known behavior of the reactions involved, namely the reduction of the formed methemoglobin by leuco methylene blue and the enzyme systems present in the erythrocytes, and the rapid disappearance of the injected dye from the blood. *In vivo* formation of methemoglobin is readily demonstrable after administration of both cyanide and methylene blue because of the stability of the cyanmethemoglobin which is formed. Considerably more than half of 2 M L D of subcutaneously administered cyanide is demonstrably bound in the circulating erythrocytes of dogs injected with methylene blue immediately before administration of the cyanide. When the dye is injected continuously throughout the period of cyanide absorption a still greater fraction of the cyanide is bound in the blood. The principal action of methylene blue in counteracting the toxic effects of cyanide appears to depend

therefore, upon methemoglobin formation. In the absence of experimental demonstration that methylene blue can replace the cyanide sensitive catalysts which are concerned with vital processes, the methemoglobin explanation appears to be all that is required —WILLIAM B WENDEL, *J, Pharmacol*, 54 (1935), 283 (H B H)

Phenolphthalein—Reactions Caused by A survey of the literature on reactions caused by phenolphthalein shows that the reports deal mainly with the general constitutional effects, *e g*, syndromes in which circulatory, renal or nervous disturbances predominate, and with cutaneous eruptions. The total number of reactions observed is small considering the extensive use of the drug. Most of the reactions were noted after a single or occasional average dose. Nine cases of systemic disturbances resulting from an overdose and 6 cases of possible cumulative action are somewhat offset by 11 reported instances of no apparent ill effects from overdosage. The laxative dose of the white phenolphthalein is 3 times that of the yellow which contains more of a residue known as the 'dark bodies'. Compounds from which phenolphthalein is prepared and related derivatives were not responsible for the cutaneous lesions, nor was the vehicle responsible for the eruptions. Chemical and microscopical examination of the blood and urine in normal persons showed no noticeable difference before and after use of the drug. Eruptions may appear after the first dose suggesting previous contact, or the occasional use of an average dose may bring on a sudden development of hypersensitivity. Phenolphthalein, but none of the other commoner drugs reproduced the cutaneous lesions. The reactions suggest an allergic response in persons sensitized to the drugs. In most cases skin tests are negative. Abramowitz assumes that there is a form of specific hypersensitiveness, allergic in nature, in patients who have eruptions due to phenolphthalein. He also suggests that other tissues besides the skin may become sensitized accounting for the general reactions that develop —E W ABRAMOWITZ *Arch Dermatol Syphilol* 31 (1935), 777, through *Squibb Abstr Bull* 8 (1935), A-974

Refrigerating Agents—Toxicity of the Newer Air conditioning apparatus is generally of the water injection type, and as the water comes into direct contact with the air that it cools, it is important that it be not contaminated through leaks by the cooling gases. The new cooling agents (ethyl chloride, dichloroethylene, dichloromethane) are less toxic than carbon dioxide, ammonia or sulphur dioxide, but all cooling agents are injurious to the human organism when they modify the composition of the atmosphere. Fluorine compounds (CF_2Cl_2 , $CFCl_3$, CF_3Cl , etc.) recently proposed in America are not without drawbacks. Efforts should therefore be directed along the lines of improvement of the apparatus to render practically impossible contamination of the cooling water or of the cooled atmosphere —R LANDSBERG *Rev Gen Froid*, 15 (1934), 239-241, through *Chimie & Industrie* 33 (1935), 1111 (A P C)

Toxicity—Relation of, to Mode of Administration After the injection of 15.5 cc procaine (scurocaine) (I) solution containing 0.00012 Gm epinephrine (adrenaline) per 3 cc or a total of 750 mg I, into the exposed femoral artery of a 13 Kg dog the dog showed an intense excitation for 10 minutes. The injected foot was used awkwardly, but was not paralyzed and the animal was completely normal on the following day. A month afterwards, the same dog, though considerably weakened from other experiments, was given 700 mg I intravenously in the same leg as previously injected. Respiration became slow and deep and after 5-6 movements ceased entirely and the heart stopped beating. With the intravenous injection 0.25-0.5 cc "soluprotin" the phenomenon of intense shock was obtained regularly, but the injection of 1 cc into the artery was followed by some local reactions but no indication of a general reaction. Similarly the injection into the artery of 20 cc acetylcholine, 1 mg epinephrine (adrenaline), 1 ampul of cobra toxin amounts which could not be injected intravenously, gave only varied local reactions. Up to 5 cc of the compound (sommifen) of 5 allyl 5-isopropyl barbituric acid with 5.5 diethyl barbituric acid diethylamine had to be injected into the femoral artery to obtain a simple quieting effect although general anesthesia was obtained with 3 cc intravenously. On the other hand the injection into the femoral artery of the sodium salt of 5 cyclohexenyl-1.5 dimethylbarbituric acid (sodium evipal) produced almost the same anesthesia as the intravenous injection. The author suggests that the injection of some of these substances into the arteries may be characterized by a loss of toxicity without a loss of the desirable effects —P GOINARD *Compt rend soc biol*, 118 (1935), 689, through *Squibb Abstr Bull*, 8 (1935), A 631

THERAPEUTICS

8-Aminoquinoline—Derivatives of, as Antimalarials IV Compounds referable to the formula

were prepared, where N is represented by 6, 7, 9 and 11, respectively. The therapeutic indices of the compounds were, in the order given 13.3, 33.3, 40 and 5. Homologs containing an uneven number of methylene groups in the side-chain were more active and had a higher index than those possessing an even number of such groups. The relatively high index of 40 in the case of the nine carbon side-chain was occasioned chiefly by the low toxicity of the compound. The preparation of the greater number of compounds was based upon the use of α - ω -glycols. By use of the dibromide and the bromido acetate, the corresponding α diethylaminoalkyl acetates were obtained. Heating the latter with hydrobromic or hydrochloric acid gave the diethylaminoalkyl bromide or chloride which was then condensed with 8-amino-6-methoxyquinoline. The stabilities of the compounds increased with the length of the side-chain. Diethylaminopentyl chloride undergoes cyclization upon distillation, the higher homologs with less ease after three to four months standing.—O. J. MAJIDSON, O. S. MADAJEWA and M. W. RUBZOW. *Arch. Pharm.* 273 (1935) 320 (L. L. M.)

Amyl Nitrite—Use of, in Cases of Contraction Ring. A paper describing the use of amyl nitrite during labor in the rare condition in which a ring of persistently contracted muscle occurs in the body of the uterus, and prevents the delivery of the child. Amyl nitrite when administered causes relaxation of this ring. The author has tested the effect of amyl nitrite upon isolated strips of human uterus suspended in a bath, but he did not observe much effect.—C. R. CROFT. *Proc. Roy. Soc. Med.*, 28 (1935), 481, through *Quart. J. Pharm. Pharmacol.*, 8 (1935), 303 (S. W. G.)

Antipyretics. Antipyretics should only be sold on a physician's order and recognized as palliatives until the irritating cause is removed. Acetylsalicylic acid (I), the least dangerous of the drugs, might be excepted from such restriction. Acetanilide (II) so loudly decried as a cause of cardiac weakness and excluded from the B. P. and Canadian Formulary is undoubtedly efficient and perhaps not more dangerous than 1,5-dimethyl-4-dimethylamino-2-phenyl-3-pyrazalone (III, amidopyrine) which has replaced it as the official drug. *p*-Aceto-phenetide (IV, phenacetin) is not so dangerous and 1,5-dimethyl-2-phenyl-3-pyrazalone (V, antipyrine, phenazone) is credited as being even less harmful. I is much less dangerous but also much less efficient. 2-Phenyl-4-quinolinecarboxylic acid (VI, cinchophen) decreases fever and pain of acute articular rheumatism and like the others, may relieve pain of chronic lesions in muscles and joints, but its use should be carefully controlled. The evidence of the use of combinations of antipyretics with sodium bicarbonate or other alkali or caffeine is drawn largely from the use of relatively acute toxic doses. Sodium bicarbonate does however protect I in the stomach and its use is a little more credible than caffeine. The synergistic effects of combinations of III and barbiturates or IV and diethyl barbituric acid (VII) have been reported. Many cases of agranulocytic leucopenia have resulted from the use of III-barbiturate combinations. The IV-VII combination might be more extensively tested. Codeine (VIII) has compared with morphine little value in relieving pain yet appears to be effective in certain headaches. Clinical experience seems to justify the combination of VIII with antipyretics. The combination IV-VII-VIII may frequently replace morphine.—V. F. HENDERSON. *Can. Med. Assoc. J.* 33 (1935), through *Squibb Abstr. Bull.*, 8 (1935) A. 989

NEW REMEDIES

SYNTHETICS

Atabrin (Winthrop Chemical Co, Inc New York N Y) is the dihydrochloride of met'oxychlor diethyl aminopentyl amino-acridine It is also known as chinacrin It is claimed to be an efficient and satisfactory agent for the treatment of malaria, destroying sexual and asexual parasites of tertian and quartan malaria and the asexual forms of tropical malaria It is marketed in tubes of 15, 0 1 Gm tablets—*Am Drug* (Mar 1935), 106 (T G W)

Prostigmin (Hoffmann-La Roche, Inc Nutley N J) is a 0 5% aqueous solution of the dimethyl carbamimic ester of meta-oxyphenyl trimethylammonium methyl sulphate a para sympathetic stimulant resembling physostigmine It shows a pronounced action on peristalsis but at the same time the less pronounced miotic influence and almost complete absence of cardiac and vasomotor effects It is administered hypodermically or intramuscularly for post operative gas pains for intestinal atony and for the severe constipation of the bed ridden and other chronic cases It should not be used with asthmatics It is marketed in cartons of 12 and 50 1 1 cc ampuls—*Am Drug* (Feb 1935) 110 (T G W)

SPECIALTIES

A P L (Ayerst, McKenna and Harrison Ltd, Rouses Point, N Y) is a preparation of the hormone of the placenta, prepared and biologically standardized in accordance with the technique of Dr Collip of McGill University It is a specific stimulant which when administered subcutaneously and intramuscularly will increase the endocrine activity of the ovary Its use is indicated in uterine hemorrhage in mastalgia and in the secondary type of amenorrhea It is not intended for intravenous use It is available in the form of a sterile standardized solution containing 100 biological day units (Collip) per cc It is marketed in boxes of 6, 1 cc ampuls and in 5 cc and 10 cc rubber stoppered bottles—*Am Drug* (May 1935), 108 (T G W)

Absorbent Medicine for Internal Use An intestinal absorbent medicine is prepared by dispersing kaolin of colloidal fineness in an aqueous dispersion of an inorganic hydroxide gel, e g aluminum hydroxide ferric hydroxide—JOHN WYETH & BROTHER Brit Pat 423 541 (Feb 4, 1935), through *Chem Abstr*, 29 (1935), 4523

Acecolox (Anglo-French Drug Co Inc New York, N Y) contains acecoline (stabilized acetylcholine hydrochloride) 2 Gm fenchone (terpenic ketone of camphor group) 10 Gm ichthyol, 1 25 Gm, titanium oxide, 2 Gm butyl para amino benzoate 1 Gm, zinc oxide, 10 Gm, excipient, q s ad, 100 Gm It is claimed that recently formed and small varicose ulcers treated by this method usually heal and cicatrize within a week, older ulcers and those with edema and lymphangitis become clean and healthy in a week and cicatrize in a month It is indicated in the treatment of varicose ulcer, atonic wounds and skin ulcerations in which there is a strong trophic factor It is supplied as an ointment in 1 oz tubes—*Drug Circ*, 79 (June 1935), 70 (T G W)

Alumin (Eli Lilly & Co, Indianapolis, Ind) is a finely subdivided powder which goes readily into suspension in water and contains kaolin 24 Gm, aluminum hydroxide, 24 Gm, calcium carbonate, 16 Gm bismuth subcarbonate, 16 Gm, sodium chloride 3 Gm, acacia 6 Gm, aromatics q s, dextrose, q s to make 100 Gm It is claimed to neutralize mineral and organic acids absorbs toxins of bacterial origin checks excess secretions from mucous membranes, and allays irritation in the gastro intestinal tract It is indicated in gastric hyperacidity and hypersecretion, useful in the presence of frank organic disease such as gastric or duodenal ulcer, also in certain cases of dysentery and diarrhea It is marketed in 4 oz and 1-lb jars—*Drug Circ* 79 (July 1935), 62 (T G W)

Aminogen (Christina Laboratories New York, N Y) is a preparation containing the sub molecular immunologic determinants of the protein molecule complex Its use is recommended in the treatment of gastro duodenal ulcers and for the abolition of muscular spasms, of the angio sperm and hyperemia and for increasing the quantity of anti pepsin and proenzymes in the blood It is administered by intramuscular injection It is supplied in packages containing 12 24 and 100 2 cc ampuls—*Am Drug* (Jan 1935), 108 (T G W)

Androcalcion H (Laboratories Cortial Paris) are found on the market as yellow colored tablets each tablet containing 0 15 Gm calcium lactate 0 05 Gm magnesium glycerophosphate

0.05 Gm theobromine, 0.02 Gm Testes pulv, and 0.02 Gm Iodaseptinum Androcalcion E is found on the market in blue colored tablets, each tablet containing 0.2 Gm calcium lactate, 0.02 Gm magnesium glycerophosphate, 0.01 Gm iodomethyl hexamethylenetetramine, 0.02 Gm Testes pulv, and 0.02 Hypophysis Lobus anterior—*Pharm Weekblad*, 72 (1935), 752

(E H W)

Antagasan (Behring works) is a lactic acid bacterial preparation used for diseases caused by bacterial infection. The lactic acid bacteria present in the preparation biologically prevent the growth of pathogenic bacteria. Antagasan has no toxic properties and also exhibits no harmful effect on the tissues. The preparation works by lessening secretion and causing the disappearance of the pathogenic germs. It is used in surgery in catarrhal ulceration of the mucous membrane, in wounds, as an irrigant in cystitis, in otitis and laryngology, in inflammation of the middle ear, etc. It is applied in tampons and gauze bandages which are changed every 24 hours. It is found on the market in bottles of 20 and 100 Gm—*Pharm Weekblad*, 72 (1935) 824

(E H W)

Anterior Pituitary Extract (E. R. Squibb & Sons New York, N. Y.) is an alkaline aqueous extract of the anterior pituitary glands of cattle, and containing the thyrotropic and sex stimulating factors of the anterior pituitary gland. It is administered intramuscularly. It is used for pituitary types of dwarfism and Simmond's disease. It is supplied in 10 cc vials containing 100 growth units—*Drug Circ*, 79 (June 1935), 25

(T G W)

Antutrin-S (Parke, Davis & Co., Detroit Mich.) is the sex hormone of the anterior pituitary as obtained from the urine of pregnancy. It is a standardized product representing in each cc, 100 rat units. It stimulates ovarian function notably the development of the corpora lutea. Its use is indicated in metrorrhagia, menorrhagia, uterine bleeding, retarded sex development and amenorrhea. It is supplied in the form of a hypodermic solution in 10 cc rubber capped vials—*Am Drug* (Apr 1935) 108

(T G W)

Arsaceticum According to the *Schweiz Apoth Zeitung* (1935), 204, the original *Arsaceticum* is no longer produced by I. G. Farben. If the product is called for under this name one should dispense sodium acetylarsanilicum, meeting the requirements of the Pharmacopoeia—*Pharm Weekblad* 72 (1935) 752

(E H W)

B. R. I. Colloid (Anglo French Drug Co., Inc., New York, N. Y.) is a lead selenide colloid that has been investigated experimentally and clinically at the Bristol (England) Royal Infirmary and found to be of value in operable carcinoma. It is also called "D.S." It is administered intravenously in 5 to 10-cc doses at weekly intervals during 8 to 12 weeks. The maximum dose is 15 cc. It is supplied in 5, 10- and 15-cc ampuls—*Am Drug* (Mar 1935), 106

(T G W)

Baldronit (Otto Reichel, Fabrik pharm u biol Erzeugnisse Berlin-Neukölln) is a sedative and hypnotic. It is an extract of 80% *Valeriana montana* and 5% *Adonis vernalis* with 12.5% of ethyl allyl barbituric acid with amidopyrine. It is useful in cardiac neurosis, neurasthenia and hypertension—*Deut Med Wochschr* 61 (1935), 1002

(H R)

Biocholine (Anglo French Drug Co., New York, N. Y.) is a physiologically tested solution of choline hydrochloride, entirely free from mono- and diethylamines. It possesses the property of rebuilding the cholesterol molecule and increasing the cholesterol content of the blood. Its use is indicated in active tuberculosis, both pulmonary and extra pulmonary. It should not be used in those diseases (e.g. diabetes) where there is already an excess of cholesterol in the blood. It is supplied in boxes of 25, 50 and 100, 1-cc ampuls (0.02 Gm of choline hydrochloride per ampul)—*Am Drug* (Apr 1935), 108

(T G W)

Biseptol (The Maltbie Chemical Co., Newark, N. J.) is a light soft, antiseptic powder containing bismuth salts, boric acid, thymol iodide, alum, menthol and other ingredients in a base of fine talcum. It is easily wetted by serous exudates. It is used as a dry surgical dressing for the treatment of skin abrasions and skin infections, and is marked in 1-oz. sprinkler top cans—*Drug Circ*, 79 (June 1935), 70

(T G W)

Bismo-Kaolin (Flint Eaton & Co., Decatur Ill.) is a white creamy liquid containing in each fluidounce 40 grains each of bismuth subcarbonate and kaolin in colloidal suspension. It contains no cathartics or oil, no sugar or alcohol. It is marketed in 4- and 16 oz. bottles—*Am Drug* (Mar 1935) 106

(T G W)

Bismurung is an ointment consisting of bismuth oxychloride in colloidal dispersion in an emollient base. It is recommended as an antiseptic ointment which is soothing and healing in any inflamed, irritated or painful condition of the skin. It is beneficial in all forms of dermatitis.

pruritus, eczema and many other conditions Bismurung is supplied in 1 oz and 2 oz tins—*Quart J Pharm Pharmacol*, 8 (1935), 317 (S W G)

Bokanol (Chatelain's Laboratories, Paris, George J Wallau, New York, N Y Dist) is a preparation containing in each case 3 cc dose 0 001 Gm of colloidal iron, 0 150 Gm of sodium glycerophosphate, 0 060 Gm of sodium cacodylate and 0 0015 Gm of strychnine cacodylate The solution is dispensed in a 3-cc ampul and is recommended in the treatment of neurasthenia chlorosis and anemia—*Am Drug* (Feb 1935), 108 (T G W)

Bromostronturan, sodium bromide strontium chloride-urea, is supplied as an intravenous or intramuscular injection, and as tablets for oral administration, for the treatment of itching dermatoses It is recommended for the treatment of acute and chronic eczema, urticaria, pruritus, neurodermatitis and other forms of dermatitis The dose in severe cases should be one 10 cc ampul injected intravenously every day In less severe cases 5 cc injected four times a week will be sufficient Bromostronturan tablets should be given 2 or 3 times daily to supplement the injections in severe cases, but may be given alone in milder cases The 10 cc ampuls are issued in boxes containing 1, 3 and 8 ampuls The 5 cc ampuls are supplied in boxes of 2 and 8 Bromostronturan tablets are issued in packages of 25 and 100—*Quart J Pharm Pharmacol*, 8 (1935), 317 (S W G)

Cal-B (The Calco Chemical Co, Inc, Bound Brook N J) is a mixture of wheat germ vitamin B and calcium gluconate It is used for the relief of calcium deficiency and the tonic effect of vitamin B It should be given only on the advice of a physician It is marketed in bottles of 4 oz—*Drug Circ*, 79 (July 1935), 60 (T G W)

Calcidex (Intravenous Products Inc, New York N Y) is a solution of colloidal calcium combined with pure dextrose Each 10 cc of the solution represents the equivalent of 6 grains of calcium hydroxide or 10 grains of calcium chloride It is administered intravenously or intramuscularly for conditions associated with calcium deficiency, such as tuberculosis bronchial asthma, bronchitis or hay-fever It is marketed in packages of 6, 25 and 100, 10 cc ampuls—*Am Drug* (Feb 1935), 110 (T G W)

Calcinate (Carroll Dunham Smith Pharmacal Co Orange, N J) are ampuls containing 0 09 Gm of calcium It is a sterile aqueous solution, less painful than calcium chloride and is tolerated to about twice the quantity It contains 13 1% calcium or nearly 50% more calcium than calcium levulinate It is administered intravenously or intramuscularly It is indicated in calcium deficiencies It is supplied in ampuls of 5 and 10 cc in boxes of 6, 25 and 100—*Drug Circ*, 79 (July 1935), 60 (T G W)

Calcio-coramine (Gesellschaft fur chemische Industrie, Basel) is a well crystallized double salt of pyridine β carbonic acid diethylamide (coramine) and calcium rhodanate It is soluble in water and has been shown by experiments on rabbits to be only slightly toxic The circulatory and respiratory stimulant action of the coramine is increased by the calcium rhodanate especially as far as the heart action is concerned Calcio coramine is found on the market in 400 mg tablets Dose 1-2 tablets three times a day—*Pharm Weekblad*, 72 (1935), 824 (L H W)

Calcium "Eci" (Electrochemische Industrie, Ltd, Roermond) is a calcium gluconate ($C_6H_{11}O_7$)₂Ca, in powdered form *Pharm Weekblad*, 71 (1935), 825 (L H W)

Calogran (Flint, Eaton & Co, Decatur, Ill) is a granular effervescent form of calcium gluconate It contains 50% of the gluconate It is designed for real calcium therapy affording easy solubility and adequate dosage It is indicated in all cases where calcium is indicated, such as edema, inflammatory conditions, exudative diathesis and weeping eczema It is supplied in 5-oz bottles—*Am Drug* (Apr 1935), 108 (T G W)

Canfidrol-Solution, Canfidrol-Ampuls (Laborat Farmacol Reggiano, Correggio, Italy) contain calcium camphosphonate and ephedrine hydrochloride put up in containers of 15 cc and in packages of 6 ampuls, 1 cc each and 3 ampuls, 5 cc each—*Pharm Presse* 40 (1935), 279 (M F W D)

Carmacin "Tabloid" (Burroughs Wellcome & Co, Inc New York N Y) contain calcium carbonate, grains 12 magnesium carbonate grains 8, sugar, grains 8, oil of peppermint, $q\ s$ The antacid effect of calcium carbonate is augmented by that of magnesium carbonate which also acts as a mild saline purgative, alkalizes the urine, and is a mild diuretic It is suitable for treatment of hyperacidity dyspepsia and heartburn The antacid properties render it useful in acute

gastric catarrh, acute gastro enteritis and gastric ulcer It is supplied in glass tubes of 25 products—*Drug Circ*, 79 (June 1935), 70 (T G W)

Caspetol (E R Squibb & Sons, New York, N Y) is a palatable combination of Squibb's tasteless castor oil with 15% of a special light mineral oil with 3% of alcohol It is marketed in 3-oz bottles—*Am Drug* (May 1935), 108 (T G W)

Cavodol tablets contain a cod liver oil concentrate with a potency of 1000 vitamin A and 500 vitamin D units, reduced iron colloidal copper, calcium iodide, berberine sulphate and extract of gentian They are recommended for the treatment of avitaminosis and anemia The adult dose is 1 to 2 tablets three times daily with water or milk Children can be given half of the adult dose Two tablets are equivalent to 1 tablespoonful of cod liver oil The tablets are supplied in bottles of 100—*Quart J Pharm Pharmacol*, 8 (1935), 318 (S W G)

Ceanothyn (Flint, Eaton & Co, Decatur, Ill) is a hydroalcoholic extract of the bark of the root of *Ceanothus americanus* containing the alkaloids of this drug in uniform solution The preparation is claimed to be a reliable hemostatic, applicable to conditions of actual bleeding largely restricted to hemostasis where capillaries are involved It is administered orally and is well adapted to routine prophylactic use in minor surgical procedure in throat and nose operations in oral surgery and in urological and gynecological work It is marketed in 1-pint bottles—*Am Drug* (May 1935), 108 (T G W)

Choloton for Injection (Chemisch Fabrik Promonta G m b H, Hamburg 26) is a solution of albumin-free liver extract, extrahepatic bile duct and bile It is supplied in ampuls and is used in liver and bile duct diseases—*Deut Med Wochschr*, 61 (1935) 1002 (H R)

Chondrocein (Christina Laboratories New York, N Y) is a cartilaginous extract consisting chiefly of purified and chemically controlled scleroproteins extremely rich in disulphide and sulphhydryl groups The administration of these sulphur compounds has found a great value in the treatment of all forms of arthritis, sciatica, neuralgia and neuritis In addition to the disulphide and sulphhydryl groups it contains scleroproteins which act as nonanaphylactic and non specific agents, thereby stimulating cellular activity and leucocytosis It is dispensed in the form of a sterile solution designed for intramuscular injection It is marketed in packages of 12, 24 and 100, 2 cc ampuls—*Am Drug* (Feb 1935), 106 (T G W)

Chromosmon (Curta & Co) is a dark blue liquid marketed in ampuls of 10 cc It is a solution of methylene blue and glucose and is used in all cases of gas poisoning, as prussic acid carbon monoxide, illuminating gas, etc—*Pharm Weekblad*, 72 (1935), 825 (E H W)

Citrofinal is a new name for the sodium chloride free kitchen salt *Citrovin* manufactured by Chem Fabrik Bad Homburg and recommended for use in salt-free diets—*Pharm Weekblad* 72 (1935) 752 (E H W)

Collosol Calcium (Crookes Laboratories, Inc, New York N Y) is an 0.85% aqueous colloidal suspension of calcium oleate (representing 0.05% of metallic calcium) designed as an effective agent in calcium therapy Its use is indicated in the treatment of tuberculosis especially when combined with iodine treatment It has also been found of value in the control of hemorrhage (ante and post operative) as a prophylactic in hay-fever and in the treatment of pelvic pains in women It is administered intramuscularly intravenously or orally It is marketed in boxes of 6, 0.5 and 1-cc ampuls, in 30 cc rubber-capped bottles, and in 8 and 16 oz bottles—*Am Drug* (Feb 1935), 108 (T G W)

Collosol Iodine (Crookes Laboratories, Inc, New York, N Y) is a loose colloidal combination of hydroiodic acid and protein suitable for administration either by the oral, subcutaneous or intravenous route It is offered in oleaginous and in aqueous solution and also in ointment form Collosol Iodine Oil may be rubbed into the skin without staining it is non-irritating and is non-coagulative of tissues and it rapidly penetrates the tissues Collosol Iodine Aqueous produces slow elimination of iodine and affords minimum danger of iodism The oil is used by local absorption in localized rheumatoid arthritis and for enlarged glands and goiter It is also used in the treatments of skin diseases, such as eczema, chilblains and ringworm of the scalp The aqueous solution is used orally in arthritis and goiter and as a spray in catarrhal conditions When injected subcutaneously, intramuscularly or intravenously it is of value in syphilis and in rheumatism Collosol Iodine Oil is dispensed in 1-, 4-, 8 and 16 oz bottles The aqueous solution (0.2% iodine) is dispensed in 4-, 8, 16 and 80 oz bottles The isotonic intravenous fluid (0.2% iodine) is dispensed in 10-cc ampuls (6 to the package) and also in 4 oz bottles The intramuscular or sub

cutaneous fluid (1% iodine) is supplied in 1-cc ampuls and in 1 oz bottles—*Am Drug* (June 1935), 110 (T G W)

Cortical-Liquid, Cortical-Ampuls (Istituto Opoterapico Pisa) contain the aqueous total extract of the fresh cortex of the suprarenal glands, put up in containers of 40 cc and in packages of 6 ampuls, 2 cc each—*Pharm Presse* 40 (1935), 279 (M F W D)

Cratægol Tablets (Carroll Dunham Smith Pharmacal Co, New York, N Y) are orange colored sugar-coated tablets each containing 2 minims of cratægus compound, 1 minim of fluid extract of apocynum, 1 grain of sodium nitrite, $\frac{1}{100}$ grain of gold and sodium chloride and $\frac{1}{100}$ grain of nitroglycerin. These tablets are indicated in high blood pressure with its attendant vertigo, nasal hemorrhage, flushed red hot skin and cardiacal complications. They are marketed in packages of 1 000 and 5 000—*Am Drug* (Mar 1935), 106 (T G W)

Crystal Violet Jelly (Caleo Chemical Co, Bound Brook, N J) is a 1% jelly of crystal violet in a water-soluble tragacanth base. It has been found to be a valuable agent in the treatment of burns. It is marketed in 4 oz and 1-lb glass jars—*Am Drug* (July 1935), 76 (T G W)

Cyclobis (Winthrop Chemical Co, Inc, New York, N Y) is composed of bismuth camphenylate, an organic bismuth compound containing 30% of bismuth. It is insoluble in water but gives a clear solution in oil; it is well tolerated, relatively non-toxic and does not produce tissue irritation at the site of the injection. It is administered intramuscularly only generally given in courses, alternating with the arsenicals. It is indicated in all stages of syphilis and is well adapted for the treatment of congenital syphilis used in conjunction with the arsenicals. It is supplied in boxes of five 2 cc ampuls of the 10% oily solution—*Drug Circ*, 79 (July 1935) 29 (T G W)

Cysteine Hydrochloride (E R Squibb & Sons, New York, N Y) is a preparation of the hydrochloride of the sulphhydryl compound cysteine, $\text{CH}(\text{COOH})(\text{NH})\text{CHSH}$, buffered with sodium borate, so as to produce a 0.5% solution having the pH 4.0. It is recommended as a wet dressing for wounds stimulating granulation and epithelial proliferation. It is marketed in 0.5 and 5.0 Gm ampuls in packages of five—*Am Drug* (Feb 1935), 108 (T G W)

Darmo-Stop-Tablets (Fa Brady and Schmidgall, Vienna, 12th dist) contain in each tablet 0.50 Gm basic calcium aluminum tannate in chocolate, 2 in a package—*Pharm Presse*, 40 (1935), 279 (M F W D)

Deriphyllin Oral (Chemisch Pharmazeutische A G, Bad Homburg, Frankfurt a M) is a solution of theophylline oxyamine containing 0.412 Gm per cc. It is used as a diuretic and cardiac tonic—*Deut Med Wochschr* 61 (1935), 1002 (H R)

Dermabella Skin Oil (Fabrik für pharm Spezialitäten, Homöopathie und Biochemie G A Reinecke, Hannover) a virgin cold pressed olive oil perfumed with natural products is used for sunburn, body and skin care and as a massage oil—*Pharm Zentralh* 76 (1935), 380 (E V S)

Devegan (Winthrop Chemical Co, Inc, New York, N Y) Tablets containing acetylaminohydroxyphenylarsonic acid, a small amount of boric acid, and a substance obtained by subjecting carbohydrates to a partial transformation by mild oxidation and hydrolysis. A destructive agent against the flagellate and cystic forms of *Trichomonas*. It furnishes a culture medium for the lactobacilli normally present in the vagina and reestablishes the normal vaginal flora and thereby aids in preventing infection by foreign organisms. It is indicated in the treatment of *Trichomonas vaginitis* and of leukorrhea due to mixed and non-specific bacterial infections. It is issued in boxes of 25 tablets—*Drug Circ* 79 (June 1935), 25 (T G W)

Dibroluur (Society for Chemical Industry, Katwijk, Netherlands) is bromdiethylacetylurea—*Pharm Weekblad* 72 (1935), 825 (E H W)

Dicalcium Phosphate with Viosterol (E R Squibb & Sons, New York, N Y) is the trade name for tablets each of which contains 9 grains of dicalcium phosphate, 6 grains of calcium glueonate and viosterol (Squibb) of the potency of 660 vitamin D units (1934 standard). The calcium phosphorus ratio is 1:625. Its use is indicated in the treatment of mild rickets in supplying calcium during pregnancy and lactation and in other conditions where calcium therapy is desirable. It is supplied in bottles of 50 tablets—*Am Drug* (Apr 1935), 108 (T G W)

Diffundol (Diffundol G m b H, Frankfurt a M) is an ointment containing soda salt ointment, ethereal oil, rectified oil of turpentine, sulphur compounds and Formoxyl hydrate. It is used as an antirheumatic—*Deut Med Wochschr* 61 (1935), 1002 (H R)

Dinitrenal Capsules (Drug Products Co., Inc., Long Island City, N. Y.) are capsules each containing alpha dinitro phenol sodium (100 mg.), suprarenal and charcoal. It is claimed to be a metabolic stimulant which accomplishes controlled reduction in weight, if not due to lack of thyroid secretion. It is used in the treatment of obesity and should only be used under the supervision of a physician. It is issued in bottles of 20 and 100 capsules—*Am Drug* (Jan 1935), 108

(T G W)

Diotrast is the name applied in the United States to the substance known in Europe as *Per abrodil* (*Quart J Pharm Pharmacol* 5 (1932) 753). It is 3,5-diiodo-4-pyridone N-acetate of diethanolamine, and is used as a urographic contrast agent. It is a white odorless powder containing 51.8% of iodine, m.p. 246–247° C. It is supplied in 20 cc ampuls containing a 35% solution, the dose intended for an adult, but it can safely be given to young children without toxic effects—*Quart J Pharm Pharmacol*, 8 (1935), 318

(S W G)

Diposal (C. F. Boehringer & Sons) is now produced as an ointment procurable in tubes and containing 5% diposal. The diposal is dissolved in oil and then worked up with other fatty constituents, the preparation being used in cases of muscular rheumatism to augment the internal therapy—*Pharm Weekblad*, 72 (1935) 752

(E H W)

Dosarter is the trade name for "collampoules" containing colloidal arsenic sodium silicate, sodium iodide sodium salicylate, analgesin and thiosinamine. It is indicated in arteriosclerosis when it is administered hypodermically in 3 cc doses. It is supplied in 3 cc ampuls—*Am Drug* (Mar 1935) 106

(T G W)

Drug Specialties and Nostrums—Certain, in Tea Form. The composition of some fourteen different tea mixtures expressed in proportionate relationship of the herbal constituents is given—W. PEYER *Süddeut Apoth.-Ztg.*, 75 (1935), 321, through *Chem Abstr.*, 29 (1935), 4519

Embrodex contains phenylethyl iodide 1% undecylenic iodide 0.2% incorporated in a non-greasy emollient base, for external application. It is suggested for the treatment of rheumatism, sciatica, arthritis, chilblains, sprains, as a chest rub in bronchitis and as an antiseptic dressing for wounds and ulcers. The absorption of embrodex causes hyperemia relieving congestion, and with the analgesic action of phenylethyl iodide gives relief from pain. Embrodex is applied 3 or 4 times daily to the affected part and rubbed gently until absorbed. It is supplied in small and large collapsible tubes in 1 lb tins, and in larger packings for hospitals—*Quart J Pharm Pharmacol*, 8 (1935) 318

(S W G)

Emmenin Liquid (Ayerst McKenna and Harrison Ltd., Montreal, Canada and Rouses Point, N. Y.) is an alcohol soluble, ether insoluble placental hormone prepared and biologically standardized by the technique employed by Dr. Collip of McGill University. It supplements the oestrogenic activity of the hypo functioning ovary and is active when administered by mouth. It is recommended in dysmenorrhea, menstrual headache, menopausal symptoms, amenorrhea and in vomiting in pregnancy. It is marketed in 4 oz bottles—*Am Drug* (Apr 1935), 108

(T G W)

Endo-Mangalac (Endo Products, Inc., New York, N. Y.) is a standardized solution of endomanganese proteinate which is superior to regular milk injections. It is indicated in pelvic infections, in neuritis, in furunculosis and in various forms of acne. It is administered intramuscularly. It is marketed in packages of 12, 25 and 100 1 cc ampuls and in packages of 12, 25 and 100, 2 cc ampuls—*Am Drug* (Feb 1935), 106

(T G W)

Endothyrim (Harrower Laboratory, Inc., Glendale, Cal. and New York, N. Y.) is the trade name for a standardized thyroid that is triple the U. S. P. strength. Its iodine content is 0.6% and it is virtually non-toxic. It is indicated in all conditions where total thyroid is given and it does the same work as one third the usual dose. It is marketed in bottles of 50 0.5 grain tablets—*Am Drug* (Feb 1935) 108

(T G W)

Entacard (Reed and Carnrick, Jersey City, N. J.) is the trade name for enteric coated tablets each containing 5 grains of sodium bicarbonate, 1/2 grain of calcium carbonate, 1/4 grain of potassium bicarbonate and 1/4 grain of magnesium carbonate. It is claimed to afford systemic alkalinization without gastric disturbance and is therefore of value in nephritis, rheumatism, diarrhea and for other disorders conditioned upon a lowered alkalinity. It is marketed in metal boxes containing 75 tablets—*Am Drug* (June 1935) 110

(T G W)

Entoral (Eli Lilly & Co., Indianapolis, Ind.) Pulvules containing killed pneumococci 25,000 million *H. influenzae*, 5,000 million streptococci, 15,000 million *M. catarrhalis* 5,000

million An immunizing antigen administered orally which will produce heterophile antibody in sufficient amounts to increase the resistance of individuals to respiratory infections One pulvule is given one hour before breakfast for seven successive mornings, thereafter, two pulvules taken each week throughout the season For children under six years of age, one half the adult dose is given It is supplied in bottles of 20 pulvules—*Drug Circ*, 79 (June 1935), 25 (T G W)

Epherheumine (Kon Pharm Fabrieken, Brocade-Stheeman & Pharmacia, Netherlands) is a combination of 500 mg acetylsalicylic acid and 15 mg ephedrine hydrochloride, in tablet form—*Pharm Weekblad*, 72 (1935), 752 (E H W)

Ephetonogen is a combination of ephedrine and adrenaline, containing in 1 cc 0.0001 Gm of adrenaline and 0.02 Gm of ephedrine It is indicated in diseases accompanied by bronchial spasm and in infectious toxic collapse The advantage claimed for this combination is that the necessary quantity of adrenaline is much reduced, and adrenaline intoxication is avoided In rhino laryngology it may be administered by painting or spraying, or as an inhalant The dose is 1 or 2 cc daily It is supplied in boxes of six 1 cc ampuls—*Quart J Pharm Pharmacol*, 8 (1935), 318 (S W G)

Estrogenic Hormone (Reed and Carnrick, Jersey City, N J) is prepared from prenatal urine in aqueous solution containing 500 rat units (approximately 1,500 international units) per cc and in oil solution containing 2,000 rats units (approximately 6,000 international units) per cc Also in oil solution of higher unitage The aqueous solution is administered by subcutaneous injection and the oil solution by intramuscular injection It is used for amenorrhoea and dysmenorrhoea associated with uterine hypoplasia, in menopausal disturbances, and certain cases of functional sterility It is supplied in the aqueous solution (500 rat units) in boxes of 1 and 6 1 cc ampuls and in the oil solution (2,000 rat units) in boxes of 1, 3 and 6 1 cc ampuls—*Drug Circ*, 79 (July 1935), 29 (T G W)

Ethacreo (Sharp & Dohme Philadelphia & Baltimore) is an elixir containing chloroform creosote, terpin hydrate calcium and sodium glycerophosphates It is claimed to possess expectorant tonic and mildly antiseptic action, identical in strength with Elixir Terpin Hydrate and Creosote, N F V but differs in color and in the basic elixir which is used to make it more palatable It is indicated in every type of cough, particularly obstinate coughs, also in the treatment of chronic coughs of long standing and in hoarseness It is issued in 1-pint and 1-gallon bottles—*Drug Circ*, 79 (July 1935), 28 (T G W)

Femivir (Anglo-French Drug Co, Inc, New York, N Y) is a pluriglandular extract combining the hormones of the female reproductive glands with a small quantity of yohimbine It is prepared from fresh glands and the extract is presented in the form of specially coated tablets which are easily absorbed It stimulates the dormant female reproductive glands and produces sexual desires and is therefore used in sexual frigidity, amenorrhoea and in sterility It is marketed in bottles of 50 and 300 tablets and also in boxes of 12 ampuls for subcutaneous injection—*Am Drug* (July 1935), 76 (T G W)

Ferrodic iron granules contain colloidal ferrous phosphate in combination with glucose and chocolate It is claimed that the iron remains in the ferrous condition indefinitely, and that it has a pleasant flavor free from the astringent taste of iron salts Suspensions in water give no reaction for ionized iron, but the iron is rapidly dissolved in hydrochloric acid as in the stomach and maximum absorption is ensured The granules are recommended for administration to children and to those liable to gastric disturbance following the use of other iron compounds A teaspoonful of ferrodic iron granules is equivalent in iron to 10 grams of Bland's pill, or 4 teaspoonfuls of Parrish's chemical food The dose is half to two teaspoonfuls taken alone or on bread and butter, or in hot or cold milk Ferrodic iron granules are sold in 1/2 lb and 1 lb screw top tins—*Quart J Pharm Pharmacol*, 8 (1935), 318 (S W G)

Ferro-Salicylate (Wm S Merrell Co, Cincinnati Ohio) contains in each fluidounce, 40 grams of natural sodium salicylate and 40 minims of tincture of ferric citrochloride in a palatable solution of ammonium citrate It is an anodyne, hematonic and tonic and does not induce gastric disturbances It is given in doses of one or two teaspoonfuls in water three or four times daily It is used for the treatment of rheumatic conditions anemias or debilitated conditions following prolonged illness, and in post-influenza convalescence It is supplied in pint bottles—*Drug Circ*, 79 (June 1935), 68 (T G W)

Flavicrine (Christina Laboratories New York N Y) is a thiazonium derivative of diamino

alkyl acridine, a dye possessing high bacteriostatic activity. It possesses low toxicity as compared to ordinary acridine dyes, is more permeable to inflamed tissues and acts equally well in acid and in alkaline urine. It is used in the treatment of gonorrhea and in renal and genito urinary infections. It is administered intravenously in the form of a 2% solution. It is marketed in the form of a 2% solution in 5 cc ampuls (6, 24 and 100 to the package) —*Am Drug* (July 1935), 76

(T G W)

Gon A-Vee 16 (G H Sherman, M D, Inc., Detroit, Mich.) is a combined antiviral (A-Vee) made from the common organisms as found in gonorrhea of the male and female tracts, incorporated into a suitable bland innocuous semi-tenacious base. It is claimed to be capable of conferring local immunity to the area injected and of controlling the mixed Neisserian infections. Used as a local injection for acute gonorrhea of the male and female. Two cc is injected deep into the male urethra and 5 to 7 cc injected at least twice weekly into the cervical canal of the female. It is supplied in packages containing five 3/4 oz tubes, one 12 1/2 cc vial of Gonococcus combined vaccine and three semi flexible metal catheters —*Drug Circ*, 79 (June 1935), 24

(T G W)

Gynocalcium M (Laboratories Cortial, Paris) is found on the market in the form of purple-colored tablets, each tablet containing 0.25 Gm calcium lactate, 0.025 Gm magnesium lactate, 0.025 Gm Testes pulv., 0.125 Gm Ovaria pulv., and 0.05 Gm calcium lactophosphate —*Pharm Weekblad*, 72 (1935), 752

(E H W)

Gynocalcium P (Laboratories Cortial, Paris) is found on the market in red colored tablets each tablet containing 0.2 Gm calcium lactate, 0.025 Gm magnesium lactate, 0.02 Gm Hypophysis Lobus ant. and 0.05 Gm calcium lactophosphate. Both Gynocalcium M and Gynocalcium P are used for amenorrhoea and other disturbances —*Pharm Weekblad*, 72 (1935), 752

(E H W)

Hexa-Chloride Compound (Pitman Moore Co., Indianapolis, Ind.) is a urinary antiseptic, each fluidounce representing methenamine, 40 grains, ammonium chloride, 40 grains, tincture hyoscyanus, 40 minims, Zea mays, dry, 40 grains, triticum 80 grains, and aromatics. It is so prepared as to increase the acidity of the urine and hence secure the full antiseptic action of the methenamine. It is used in all conditions indicating the administration of methenamine, including many forms of cystitis, certain gonorrheal conditions and other urinary infections. It is supplied in pint bottles —*Drug Circ*, 79 (July 1935), 60

(T G W)

Hexylresorcinol Crystoids (Sharp & Dohme, Philadelphia & Baltimore). Each crystoid contains 0.2 Gm of crystalline hexylresorcinol, enclosed in a hard gelatin covering. It is used to control round worm (*Ascaris*) and hookworm (*Uncinaria*) infestations. It is marketed in packages of six vials, each vial containing five crystoids —*Drug Circ*, 79 (June 1935), 24

(T G W)

Hydronal (I G Farbenindustrie, Bayer) is colloidal aluminum hydroxide prepared by a special method and of such a grade that at 37° it allows a certain quantity of N/10 hydrochloric acid to remain in the gastric juice so as to allow the activity of pepsin to proceed undisturbed. Two-3 tablets are given before meals as a prophylactic and 1-2 tablets are taken after meals in hyperacidity. The tablets contain 0.5 Gm hydronal —*Pharm Weekblad*, 72 (1935), 825

(E H W)

Idracaine (J D Riedel Chemical Factory) is a mixture of 0.5 Gm Idragine (Acid acetylsalicylicum, Riedel) and 0.05 Gm caffeine in tablet form —*Pharm Weekblad*, 72 (1935), 752

(E H W)

Idragine is the name given by A G Riedel to acetyl salicylic acid manufactured by them —*Pharm Weekblad*, 72 (1935), 752

(E H W)

Injectable Liver Extract, Abbott (Abbott Laboratories, North Chicago, Ill.) contains in each cc an extract derived from 50 Gm of fresh, edible, mammalian liver by a process of fractionation and concentration which conserves the pernicious anemia factor. It is used for intramuscular injection in the treatment of pernicious anemia. It is issued in boxes of ten 1-cc vials —*Drug Circ* 79 (July 1935), 29

(T G W)

Iodaseptine (Laboratories Cortial, Paris) is a compound of benzomethylphenylester. It contains 42% iodine, is not toxic and does not give rise to local reactions. It is used in rheumatism, tuberculosis and arteriosclerosis. It is found on the market in 10% solution in ampuls and in tablets containing 0.2 and 0.5 Gm iodaseptine. Iodaseptine with salicyl contains 76 mg of sodium salicylate per cc. It is put up in ampuls of 5 and 10 cc —*Pharm Weekblad*, 72 (1935), 752

(E H W)

Iosicol (Factory for Chemical and Pharmaceutical Preparations of Pharmacist P Bolder Keulen Netherlands) is a solution of 2 Gm of potassium iodide in colloidal silicic acid solution. It is used in arteriosclerosis — *Pharm Weekblad*, 72 (1935), 753 (E H W)

Jectovin (McKesson & Robbins, Inc., Bridgeport Conn.) is a sterile neutral solution of vitamin A (100 000 units per cc., U S P X 1934 Revised) and vitamin D (12,500 units per cc., U S P X 1934 Revised) in sesame oil. It is rapidly absorbed when periodically injected intramuscularly in the gluteal regions. The dose is $\frac{1}{2}$ to 1 cc weekly or semi monthly. It is indicated in pregnancy, rickets, tuberculosis and in all cases of depletion of vitamin reserve as in chronic ailments or because of severe regulated dietaries. It is especially adaptable in conjunction with calcium and phosphorus therapy in the treatment of fractures with delayed knitting. It is supplied in vials of 5 cc — *Drug Circ*, 79 (July 1935), 28 (T G W)

Kataline (Society for Chemical Industry, Katwijk Netherlands) contains phenacetine, dimethylamidoantipyrine, caffeine, quinine sulphate and is sold in tablets containing 350 mg of the mixture — *Pharm Weekblad*, 72 (1935), 825 (E H W)

KLX tablets contain in each: herba capsellæ 0.05 Gm, cortex cinnamomi 0.05 Gm, folia matieo 0.05 Gm, *Valeriana officinalis* 0.05 Gm, potassium iodide 0.3 Gm. They are recommended for the treatment of functional cases of menorrhagia and dysmenorrhœa. In ordinary cases one tablet taken three times daily for three days will be sufficient, but in severe cases the dose can be increased to 4 tablets — *Quart J Pharm Pharmacol*, 8 (1935), 319 (S W G)

Kolag (Kolag Co., New York, N Y) contains colloidal kaolin, finely powdered agar, sodium sulphocarbolate, lactose and aromatics. It is indicated in the treatment of colitis and allied intestinal disfunctions, its tendency is to produce normal bowel movement without catharsis, the emulsion form has the added lubricative powers of mineral oil. It is supplied as plain or alkaline powder in 4 oz, 8 oz and 24 oz sizes and in the emulsion form in pints — *Drug Circ*, 79 (June 1935), 70 (T G W)

Lactozym Alfa (Bacteriological and Therapeutic Laboratory of Prof J Mezzodoli, Bologna) is the normal lactic acid forming proteolytic ferment of the stomach and intestines dispensed in potable form in ampuls — *Pharm Weekblad*, 72 (1935), 753 (E H W)

Liviron (Christina Laboratories New York N Y) is a concentrated liver extract with iron. It is a sterile aqueous solution containing a nitrogenous non protein fraction G which Colin, Minot and Murphy obtained from fresh mammalian liver. Each cc of the solution represents approximately 33 Gm of whole fresh liver, plus 4 mg of physiologically active ferrous iron. It is employed intramuscularly in the treatment of pernicious and secondary anemia. It is supplied in packages of 12, 24 and 100 1 cc ampuls — *Am Drug* (Mar 1935), 106 (T G W)

Luteal Ampuls (Istituto Opoterapico, Pisa) contain the aqueous total extract of the corpus luteum, sold in packages of 6 ampuls 1 cc each — *Pharm Presse*, 40 (1935), 278 (M F W D)

Magganon Asthma Powder (A G fur medizinische Producte, Berlin N65) contains the alkaloids of ephedra, aristolochia and aspidosperma, potassium iodide, and antipyrines. It is used for bronchial and cardiac asthmas — *Pharm Zentralh*, 76 (1935), 353 (E V S)

Mastal-Liquid, Mastal-Ampuls (Istituto Opoterapico Pisa) are the aqueous total extract of fresh mammary glands put up in 60 cc containers and in packages of 12 ampuls 2 cc each — *Pharm Presse*, 40 (1935), 279 (M F W D)

Merphenyl (Hamilton Laboratories, Inc. Hamilton Ohio) is the trade name for a series of preparations containing basic phenylmercuric nitrate. These preparations afford new and effective agents for the control of pathogenic bacteria, fungi and yeast. The Merphenyl preparations include *Merphenyl Nitrate Solution* — A 1 1500 aqueous solution used as a general antiseptic and for injections of the vagina and cervix. It is supplied in 16 oz bottles. *Merphenyl Nitrate Ointment* — A 1 1500 ointment in an oycholesterol base. It is a rapidly absorbed fungicide and antiseptic of value in a number of skin infections. It is supplied in 1 oz tubes and in 1 lb jars. *Merphenyl Nitrate in Glycerin* — A 1 1000 solution used in mouth and throat infections. It is supplied in 2-oz bottles. *Merphenyl Picrate Tincture* — A 1 200 phenylmercuric picrate solution the solvent being a mixture of acetone, alcohol and water. It is an effective preparation for preoperative skin sterilization. It is supplied in 2 oz bottles — *Am Drug* (May 1935), 109 (T G W)

Metamucil (G D Searle & Co. Chicago Ill.) is the trade name for the mucilaginous con

stituents of the seed of *Plantago ovata* held in dispersion with a specially prepared milk powder. It is recommended as a useful adjuvant in the treatment of constipation, coprostatitis and colitis. It does not irritate the gastric or intestinal mucosa and does not interfere with the digestion. It is supplied in 6-oz and 1 lb containers—*Am Drug* (June 1935), 110 (T G W)

Minerasal (G D Scarle & Co, Chicago, Ill) is a granular effervescent mineral food and body alkalinizer containing 14 mineral salts required by the body cells in the proportions suggested by a study of the mineral content of human milk. It is neither diuretic nor laxative in action. Its use is indicated in the treatment of acidosis or hypoalkalinity, gastric hyperacidity, general debility. It is claimed to be of value in the treatment of peptic ulcer. It is supplied in 4 oz screw capped bottles (12 to the carton)—*Am Drug* (July 1935), 76 (T G W)

Miosal-Liquid, Miosal-Ampuls (Istituto Opoterapico, Pisa) contain the aqueous total extract of fresh bovine muscles, put up in containers of 40 cc and in packages of 12 ampuls of 2 cc each—*Pharm Presse*, 40 (1935) 279 (M F W D)

Mucidan Cough Drops (Rhenania, Pharm Abt der Kali-Chemie AG, Berlin NW7) contain ammonium thiocyanate in combination with the saponins of primrose, thyme and polygala, and a calcium salt—*Pharm Zentralh*, 76 (1935), 353 (E V S)

Natrico Pulvoids (Drug Products Co, Inc, Long Island City N Y) are enteric coated green tablets containing potassium nitrate, sodium nitrite, *cretagus oxyacantha* and nitroglycerin (1/250 grain per tablet). Their use is indicated for the prevention of cerebral and cardiac accidents and for the symptomatic treatment of hypertension. They are marketed in bottles of 100 tablets—*Am Drug* (Feb 1935), 110 (T G W)

Neda Hair Tonic, Clinical (Neda-Werk, Eduard Palm, Munchen 13), a remedy to prevent loss of hair, contains dilute alcohol, tincture of cantharides, salicylic acid, tannic acid, pilocarpine hydrochloride and oil of bay—*Pharm Zentralh*, 76 (1935), 353 (E V S)

Neo-Trepol (Anglo-French Drug Co, Inc, New York, N Y) is a precipitated bismuth in an aqueous isotonic solution. It is administered by intramuscular injection for those forms of syphilis where the use of bismuth is indicated. It is marketed in packages of 6 and 12, 3 cc ampuls—*Am Drug* (Jan 1935), 108 (T G W)

Nupercainal (Ciba Co, Inc, New York, N Y) is an analgesic and antipruritic ointment containing 1% of alpha-butoxyloxyacetic acid diethyl ethylenediamide (nupercaine) blended with lanolin and petrolatum. The prolonged anesthetic action makes the ointment especially valuable for the relief of pain and itching, occurring in affections of the skin and mucous membranes. It is indicated in burns, sunburn, ordinary eczema, cracked nipples, chapped skin, hemorrhoids and other painful and itching conditions of the skin. It is marketed in 1 oz collapsible tubes and 1 lb tins—*Am Drug* (Feb 1935), 106 (T G W)

Olaixin ointment (Olaixin-Werke, Arzneimittelfabrik, Essen Kray), a wound and healing salve for eczema, sores and cutaneous sufferings, is prepared from almond oil (28.0 Gm), phenol (25.0 Gm), lemon oil (1.5 Gm), precipitated sulphur (10.5 Gm), wax (10.0 Gm) and vaseline (25.0 Gm)—*Pharm Zentralh*, 76 (1935), 353 (E V S)

Oholase (Anglo French Drug Co, Inc, New York, N Y) is an iodized oil (40% iodine) designed for radiological examinations. Its use is indicated in the Roentgenological visualization of the spinal canal, the female generative organs and other cavities of the body. It is also of value for intensive iodine chemotherapy without iodism. The administration for radiological examinations is performed according to a special technique, for iodine medication it is administered intramuscularly. It is marketed in boxes of 10, 1-cc ampuls, 6, 2 cc ampuls, and 4, 5 cc ampuls, and in 12 cc bottles—*Am Drug* (Feb 1935) 106 (T G W)

Orgabroom (N V Organon Oss, Netherlands) is a bromine preparation in the form of bouillon cubes prepared with meat extract and vegetable products. Each cube contains 1.2 Gm sodium bromide with vegetable and animal amino acids and peptones. The sodium chloride content is not more than 40 mg per cube. Dose 1-2 cubes, one to two times a day—*Pharm Weekblad*, 72 (1935), 753 (E H W)

Osnol is the new name for *Rheumosnal* (*Pharm Zentralh*, 75 (1935), 336)—*Pharm Zentralh*, 76 (1935) 354 (E V S)

Otalgan is a 5% solution of phenazone in anhydrous glycerin, and is recommended for treatment of non perforated otitis media, and all painful affections of the ear. Sufficient otalgan should be instilled into the ear to fill the acoustic passage. It should be warmed and hot or moist

poultices should not be applied Otagan is a colorless liquid and does not interfere with otoscopic examination It is supplied in bottles of 6 and 10 cc—*Quart J Pharm Pharmacol* 8 (1935) 319 (S W G)

Ovaria Siccata (N V Organon) is no longer prepared defatted, as it has been found that the active constituents (Progesterone and Menformon) are very soluble in fats The undefatted powder is grayer in color—*Pharm Weekblad*, 72 (1935), 825 (E H W)

Pantheric Tablets (Parke, Davis & Co, Detroit, Mich) are enteric coated and chocolate coated tablets containing 5 grains of triple strength pancreatin These are of value in intestinal indigestion and its consequences, such as underweight, fermentative colitis and certain forms of food allergy They are marketed in bottles of 100 and 500 tablets—*Am Drug* (May 1935), 108 (T G W)

Pellitol (Pitman Moore Co, Indianapolis Ind) contains resorein 5%, bismuth subnitrate bismuth subgallate, oil of cade, zinc oxide, calamine and echinacea in a special lanum petrolatum base It is a protective, anodyne and astringent stimulating healthy granulation and reducing scar tissue to a minimum It is used in subacute and chronic eczemas burns, scalds *pruritis ani* and *vulva* and all conditions in which the skin is broken or destroyed It is issued in ounce collapsible tubes and ounce quarter pound and pound jars—*Drug Circ*, 79 (June 1935) 68 (T G W)

Percamal (Gesellschaft für Chemische Industrie Basel) contains 1% Percarnum and is a convenient absorbing ointment constituent to which also is added Aqua Hamamelidis and solution of aluminum formate It is used among other things to diminish the pain in burns inflammation of the nipples decubitis, intertrigo, anus fissures, sunburn, etc It is found on the market in tubes of 20 to 40 Gm—*Pharm Weekblad*, 72 (1935), 825 (E H W)

Peristaltine (Ciba Company, Inc, New York, N Y) is a preparation of water soluble glucosides of casearia sagrada It is claimed to produce a laxative effect in 8 to 10 hours, without irritation or disturbance of the digestive tract It is administered orally or hypodermically It is used in all types of chronic constipation, as a prophylactic in intestinal stasis to avoid distension before or after laparotomy It is marketed in bottles of 15, 1 1/2 grain sugar coated tablets and in cartons of 5 and 20 2 1/2 grain (15 cc) ampuls—*Drug Circ* 79 (June 1935) 24 (T G W)

Per-Joodtheodural (Society for Chemical Industry, Katwijk Netherlands) contains calcium salicylate with calcium theobromine, 417 mg, potassium iodide 83 mg, papaverine HCl 30 mg per tablet The tablets are used in high blood pressure, arteriosclerosis etc—*Pharm Weekblad*, 72 (1935), 826 (E H W)

Pertussis Vaccine (Sauer) (Parke, Davis & Co, Detroit Mich) is a bacterial vaccine prepared according to the formula of Dr Louis W Sauer, of Northwestern University Medical School who has used the vaccine successfully in hundreds of children during the past seven years It is an effective immunizing agent against whooping-cough The immunity is established in four months and lasts for five years It is administered by intramuscular injection in each arm, three administrations being sufficient It is supplied in an 8 cc rubber diaphragm capped vial—*Am Drug* (Jan 1935), 108 (T G W)

Phenandryne (Schieffelin & Co New York, N Y) is the acetic acid ester of phenol It is a clear colorless fluid insoluble in water It is a powerful germicide killing such micro organisms as *Staphylococcus pyogenes*, pneumococcus streptococcus and *bacillus coli* It is a non irritating non-caustic analgesic and has proved of value in dental work It is marketed in packages of 12 3 5 Gm bottles—*Am Drug* (Feb 1935) 106 (T G W)

Phos-Cal (McKesson & Robbins Inc Bridgeport, Conn) is a preparation containing approximately 20 0% calcium and 11 7% phosphorus prepared from pasteurized milk by a special process which removes fats and casein but recovers the unaltered calcium phosphorus milk minerals plus the globulin protein fraction as they occur in fresh milk It is indicated in the treatment of calcium deficiencies and in all cases where increased calcium phosphorus intake is indicated It is issued as the powder in 8-oz bottles and as lozenges in bottles of 18 and 100—*Drug Circ* 79 (June 1935) 25 (T G W)

Phytine (Ciba Co Inc New York, N Y) are tablets composed of calcium magnesium inositol hexaphosphate acid and containing 12% calcium, 22% phosphorus, 1 5% magnesium in organic combination It is indicated wherever calcium and phosphorus in a readily assimilable

form is desired, in rickets, osteomalacia, delayed union of fractures, asthma, vasomotor rhinitis, urticaria, tetany, spasmophilic expressions in young children, also useful in nervous affections, convalescence, tuberculosis, pregnancy and lactation. It is issued in bottles of 40, 4 grain tablets—*Drug Circ*, 79 (July 1935), 62 (T G W)

Plastosol is an antiseptic liquid plaster containing copper guaiacol sulphonate and pectrodine, dissolved in a volatile organic solvent. Pectrodine is a new iodine compound of the nature of an ethereal oily liquid which penetrates into crevices and has a stimulant antiseptic action. Copper guaiacol sulphonate coagulates albumins and acts as an astringent and styptic. Plastosol is suggested as a handy first aid dressing for wounds, and for use on operative wounds and varicose and other ulcers before the application of other dressings. It is supplied in bottles fitted with a flattened dropper with which it can be applied. Plastosol is issued in a standard size, and 4-oz dispensary size bottles—*Quart J Pharm Pharmacol*, 8 (1935), 319 (S W G)

Postalan Hemorrhoidal Ointment (Fürstl Fürstenberg, Hofapotheke, R. Baur in Donaueschingen) is prepared from ethyl *p* aminobenzoate (5 Gm), bismuth subgallate (5 Gm), zinc oxydate (7.5 Gm), extract of witch-hazel (1.25 Gm), balsam of peru (1.25 Gm), tannic acid (0.5 Gm), menthol (0.5 Gm), and simple ointment (29.0 Gm)—*Pharm Zentrallh*, 76 (1935), 354 (E V S)

Proctoids are suppositories containing zinc oxide 10.00, boric acid 10.00, bismuth oxyiodide 1.67, bismuth subcarbonate 8.33, belladonna, powdered extract, 0.50, ephedrine sulphate 0.1, balsam of peru 1.0, cacao butter to 100. These suppositories are recommended for the treatment of painful and bleeding piles. They combine the astringent and antiseptic qualities of zinc oxide and boric acid, with the antiphlogistic properties of bismuth oxyiodide and the vasoconstrictive effect of ephedrine sulphate. It is an advantage to irrigate the rectum with hot saline or bicarbonate solution before the introduction of a suppository. Proctoids are of "torpedo" shape to facilitate their retention. They are supplied in boxes of 12—*Quart J Pharm Pharmacol*, 8 (1935), 320 (S W G)

Progravid (Renova, Laboratorium für Medizin, Kottbus) is a tablet containing 0.4 Gm cerium oxalate, phenacetin and amidophenazone. It is used in pregnancy vomiting—*Deut Med Wochschr*, 61 (1935), 1003 (H R)

Prokluman (Ciba Co., Inc., New York, N. Y.) or "sistomensin Compound" is the name given to tablets containing sistomensin (ovarian hormone, Ciba), nitroglycerin, amidopyrine, caffeine-sodium-salicylate and peristaltine, Ciba. It is used in the treatment of disturbances connected with the menopause such as ovarian deficiency, depression or exaltation, tachycardia, insomnia and headache. It is supplied in bottles of 40 and 100 tablets—*Am Drug* (Jan 1935), 108 (T G W)

Prolisal (Schering & Glatz, Inc., New York, N. Y.) is the trade name for 'Elixir Alcalinus Salicylatis' a preparation designed for the treatment of colds. Each fluidounce contains 40 grains of sodium citrate, 16 grains of sodium salicylate, 8 grains of potassium guaiacol sulphonate, 24 grains of urotropin and 1.5 grains of extract of cascara combined in an aromatized special elixir. It is marketed in 8 oz bottles—*Am Drug* (Feb 1935), 110 (T G W)

Proviron (Schering Kahlbaum, Berlin) is a standardized male sex hormone. It is found on the market in ampuls—*Pharm Weekblad*, 72 (1935), 826 (E H W)

Puerpal Fever-Serum ("Behringwerke" I. G. Farbenindustrie) is a concentrated streptococcus serum obtained from streptococcus puerpal sepsis—*Deut Med Wochschr*, 61 (1935), 1003 (H R)

Remonol (Seydel Chemical Co., Jersey City, N. J.) is resorcinol mono acetate. It is a thick syrupy oily liquid soluble in alcohol, benzol, chloroform, acetone, and solutions of alkalis. It is insoluble in water. It is indicated for external applications in inflamed conditions of the skin, such as barbers' itch. It is usually applied in alcohol or acetone solution or in the form of an ointment. It is marketed in 1 lb containers—*Am Drug* (Mar 1935), 106 (T G W)

Rhinitol contains menthol 0.5, eucalyptol 0.5, chloral camphor 0.1, chlorthymol 0.01, azulen 0.2, ephedrine 0.25, vasogen to 100. It is recommended as a prophylactic against the common cold. Vasogen is a chemically treated liquid paraffin which readily emulsifies with water and it is claimed that this property increases the efficacy of rhinitol—*Quart J Pharm Pharmacol*, 8 (1935), 320 (S W G)

Rugar (McKesson & Robbins Inc., Bridgeport, Conn.) consists of colloidal barium sul-

phate dispersed in an adhesive medium It coats and paints the lining mucosa in clear outline, thus visualizing the folds of rugæ of the gastro intestinal tract, and facilitates early diagnosis It is used as a contrast medium which enables the early diagnosis of the diseases of the œsophagus stomach and intestines It is supplied in 10 oz jars —*Drug Circ* 79 (June 1935), 68 (T G W)

Ruthmol is a chloride-free table salt, composed of fruit extractives and mineral substances with a sodium and potassium base It can be used as a substitute for common salt in all cases where a salt-free diet is prescribed, such as cardiac disease, with decompensation, renal disease arterio sclerosis, tuberculosis and obesity Its taste is indistinguishable from that of sodium chloride, and it possesses the same power of giving piquancy to otherwise tasteless insipid foods Ruthmol is sold in containers of suitable shape for the table and in 1-lb jars —*Quart J Pharm Pharmacol*, 8 (1935), 320 (S W G)

Ryzamin-B (Burroughs Wellcome & Co New York, N Y) is a concentrated and purified fraction of rice polishings, in the form of a thick palatable syrup It has a minimum potency of 50 international units of vitamin B₁ per Gm It is used as a dietary reinforcement for patients of all ages to stimulate appetite and promote utilization of food, also in the specific treatment of beri beri, sprue and other abnormal conditions due to a serious deficiency of vitamin B₁ It is supplied in tubes of ½ oz and jars of 8 oz —*Drug Circ* 79 (June 1935), 68 (T G W)

Sanosin (Chemische Fabrik Perdynamin G m b H Berlin O) is a tablet containing quinine hydrochloride and caffeine each 0.025 Gm, phenacetin 0.1 Gm and amidopyrine 0.076 Gm It is used as an antineuralgic and antipyretic —*Deut Med Wochschr*, 61 (1935), 1003 (H R)

Sarcoptol is a combination of colloidal sulphur with other antiseptic, antiparasitic and analgesic ingredients recommended for the treatment of scabies, seborrhœas, pruritis, eczema, acne and alopecia It is non-toxic and non-irritating and does not stain the skin, linen or clothing It is applied with friction until completely absorbed In cases where the skin is unduly sensitive it may be diluted with 1 part of olive oil to 4 or 5 parts of the liquid In scabies a single application with friction, preceded by a warm bath usually effects a cure Sarcoptol is supplied in 2 oz and 4-oz bottles —*Quart J Pharm Pharmacol* 8 (1935), 320 (S W G)

Sav-Skin (The Doak Co., Cleveland, Ohio) is a protective ointment composed of zinc hydroxide cream It is used as a protection against irritating substances such as liquids, fumes or dusts, helpful in the prevention of industrial dermatitis It is supplied in 4 oz and 1 lb jars —*Drug Circ*, 79 (July 1935), 60 (T G W)

Scilloral (Asta A G Chemische Fabrik, Brackwede) is a cardiac substance obtained from *Bulbus scilla* It is supplied in capsules, liquid and suppository form —*Deut Med Wochschr*, 61 (1935), 1003 (H R)

Sedozym (Chemisch-Pharmazeutische A G Bad Homburg Frankfurt a M) is a dry vitamin containing yeast extract with 50% calcium and ammonium bromide It is used as a sedative —*Deut Med Wochschr* 61 (1935), 1003 (H R)

Septicemine (Laboratories Cortial Paris) is a crystallized combination of urotropin with iodine and benzomethyl (methyl benzoate?) It contains 33% iodine It is found on the market in ampuls of 4 cc containing a 10% solution in tablets of 0.2 and 0.5 Gm and in drops Septicemine is employed in acute infections, influenza, broncho pneumonia, septicemia, etc The injections are administered intravenously or intramuscularly —*Pharm Weekblad* 72 (1935), 753 (E H W)

Silver-Col (McKesson & Robbins Inc Bridgeport Conn) contains 0.8% eucalyptol 0.15% silver abietate dispersed in liquid petrolatum 80-85 Saybolt at 100° F It is claimed to be a highly germicidal colloidal organic silver compound It is indicated in the prophylaxis and treatment of specific urethritis, congested conditions of the nasopharynx in gynecology for topical application and urethral instillation also for skin infections It is marketed in 2-oz bottles —*Drug Circ*, 79 (July 1935), 62 (T G W)

Sodium Racemic Lactate (Parke Davis & Co Detroit, Mich) is a molar solution of sodium racemic lactate a chemical found by Hartmann and Senn to be of distinct value in the correction of acidosis and for the alkalization of the urine It may be sterilized either by boiling or by autoclaving It is administered intravenously intraperitoneally or subcutaneously and may also be used orally It is supplied in 40 cc ampuls in packages containing 1.6 and 25 ampul —*Am Drug* (Feb 1935), 106 (T G W)

Sorcin Sclerosing Solution (Wm S Merrell Co, Cincinnati, Ohio) is a solution composed of 5% Sorcin Merrell (sodium ricinoleate 97 to 98% with minute quantities of sodium oleate and sodium linoleate) in distilled water. The pH of the solution is adjusted to approximately 8.0 to assure a stable chemical compound which may be relied upon to produce uniform clinical results in sclerosing varicose veins, a powerful hemolyzing agent forming a soft gelatinous clot which effectively but slowly organizes obliterating varicosities, when introduced into the vein it causes formation of a soft jelly-like thrombus which adheres to the lining of the vein resisting resolutions and absorption, thus an effective obliteration of the vein is produced. It is supplied in 20 cc puncturable cap vials—*Drug Circ*, 79 (July 1935), 28 (T G W)

Sulisocol (Drug Products Co, Inc, Long Island City, N Y) is the trade name for 'Hypo-sols' or (ampuls) containing a clear sterile aqueous isotonic solution of colloidal sulphur. The solution contains 1% of colloidal sulphur. It is administered intravenously or intramuscularly for the treatment of various forms of arthritis and of certain abnormal dermatological conditions. It is supplied in packages of 25 and 100, 1- and 2 cc ampuls—*Am Drug* (Mar 1935), 106 (T G W)

Sulphocide (The Columbus Pharmacal Co) consists of soluble alkaline polysulphides with betanaphthol and aromatics in a special liquid soap. It is used as an antiseptic solution for the prevention and eradication of certain fungus and parasitic invasions. It is supplied in 3 oz bottles—*Drug Circ*, 79 (June 1935), 70 (T G W)

Thiohisarson (Christina Laboratories, New York, N Y) is composed of the sodium salt of a bismuth derivative of pentavalent organic ester of aminosulphone arsenic acid containing approximately 36% bismuth and 13% arsenic. It is claimed to prevent leucopenia, to cause a rapid disappearance of the treponema from primary and secondary specific lesions. It is used intramuscularly in the treatment of primary, secondary and tertiary syphilis. It is supplied in boxes of 24 and 100, 2-cc ampuls—*Drug Circ*, 79 (July 1935), 62 (T G W)

Thioglycerol Solution 1 50 (Abbott Laboratories, North Chicago, Ill) is a solution of 1 part by weight of thioglycerol in 50 parts by volume of glycerin. It stimulates the growth of epithelial tissue, causes lymph to flow outward toward the wound, produces granulation and epithelial proliferation. It is used in sluggish wounds, due to burns, lacerations or other traumata, varicose ulcers, bed sores, skin grafting. It is issued in boxes of six, 5 cc bottles and bottles of 50 cc—*Drug Circ*, 79 (June 1935), 24 (T G W)

Triglucon (McNeil Laboratories, Phila Pa) is the trade name for capsules representing a combination of iron, copper and calcium gluconates. Each capsule contains 0.032 Gm of iron, 0.00064 Gm of copper plus a sufficient quantity of calcium gluconate. It is an effective alterative and tonic for use in simple and nutritional anemias. It is supplied in both capsules and tablets in bottles of 100, 500 and 1 000—*Am Drug* (Apr 1935), 108 (T G W)

Urgum (The Calco Chemical Co, Inc, Bound Brook, N J) is a mixture of two non water soluble glucosides, scillonin-A and scillonin B derived from squill. Each tablet contains 0.5 mg and each cc of solution contains 1 mg. Its cardiac action is essentially similar to that of digitalis. It is useful in cardiac decompensation in the cardiac arrhythmias in cardiorenal edema. It is issued in bottles of 100, 500 and 1 000 tablets and in solution in bottles of 1 oz, 6 oz and 12 oz—*Drug Circ*, 79 (July 1935), 29 (T G W)

Urinne (Rathkamp Company of Batavia) is the name given to a mixture of vegetable drugs used in the treatment of catarrh of the bladder, kidney and bladder stones. What these East Indian drugs are is not stated. Dr J Blomberg, The Hague is the Netherlands agent—*Pharm Weekblad*, 72 (1935) 753 (E H W)

Verodigen (C F Boehringer and Sons, Mannheim) is a digitalis preparation. It comes on the market in 0.8 mg ampuls corresponding to 0.1 Gm digitalis leaf. Previously Verodigen was only obtainable in tablet form due to the fact that the solution does not keep well. In the new package it occurs in powdered form, i.e., 0.8 mg of Verodigen mixed with 100 mg of glucose. Beside this an equal number of ampuls of double distilled water are enclosed in which the powder may be dissolved just previous to the injection—*Pharm Weekblad*, 72 (1935), 753 (E H W)

Vibeta (Dr Georg Henning, Berlin) is a preparation which is claimed to contain vitamin E. In 1926 Evans and Burr demonstrated that a diet of food free from vitamin E resulted in sterility. They therefore assumed the presence of an antisterility factor which they named vitamin E. One of the richest materials in vitamin E was wheat germ oil. The administration of this oil to women

phate dispersed in an adhesive medium. It coats and paints the lining mucosa in clear outline thus visualizing the folds of rugæ of the gastro intestinal tract, and facilitates early diagnosis. It is used as a contrast medium which enables the early diagnosis of the diseases of the œsophagus, stomach and intestines. It is supplied in 10 oz jars—*Drug Circ*, 79 (June 1935) 68 (T G W)

Ruthmol is a chloride free table salt composed of fruit extractives and mineral substances, with a sodium and potassium base. It can be used as a substitute for common salt in all cases where a salt-free diet is prescribed, such as cardiac disease, with decompensation, renal disease, arterio sclerosis, tuberculosis and obesity. Its taste is indistinguishable from that of sodium chloride and it possesses the same power of giving piquancy to otherwise tasteless insipid foods. Ruthmol is sold in containers of suitable shape for the table and in 1 lb jars—*Quart J Pharm Pharmacol*, 8 (1935) 320 (S W G)

Ryzamin-B (Burroughs Wellcome & Co, New York, N Y) is a concentrated and purified fraction of rice polishings, in the form of a thick palatable syrup. It has a minimum potency of 90 international units of vitamin B₁ per Gm. It is used as a dietary reinforcement for patients of all ages to stimulate appetite and promote utilization of food, also in the specific treatment of beriberi, sprue and other abnormal conditions due to a serious deficiency of vitamin B₁. It is supplied in tubes of 1/2 oz and jars of 8 oz—*Drug Circ*, 79 (June 1935) 68 (T G W)

Sanosin (Chemische Fabrik Perdynamin G m b H Berlin O) is a tablet containing quinine hydrochloride and caffeine each 0.025 Gm, phenacetin 0.1 Gm and amidopyrine 0.075 Gm. It is used as an antineuralgic and antipyretic—*Deut Med Wochschr*, 61 (1935) 1003 (H R)

Sarcoptol is a combination of colloidal sulphur with other antiseptic, antiparasitic and analgesic ingredients recommended for the treatment of scabies, seborrhœas, pruritis, eczema, acne and alopecia. It is non-toxic and non-irritating and does not stain the skin, linen or clothing. It is applied with friction until completely absorbed. In cases where the skin is unduly sensitive it may be diluted with 1 part of olive oil to 4 or 5 parts of the liquid. In scabies a single application with friction, preceded by a warm bath, usually effects a cure. Sarcoptol is supplied in 2 oz and 4 oz bottles—*Quart J Pharm Pharmacol*, 8 (1935) 320 (S W G)

Sav-Skin (The Doak Co, Cleveland, Ohio) is a protective ointment composed of zinc hydroxide cream. It is used as a protection against irritating substances such as liquids, fumes or dusts, helpful in the prevention of industrial dermatitis. It is supplied in 4-oz and 1 lb jars—*Drug Circ*, 79 (July 1935) 60 (T G W)

Scilloral (Asta A G Chemische Fabrik, Brackwede) is a cardiac substance obtained from *Bulbus scilla*. It is supplied in capsules, liquid and suppository form—*Deut Med Wochschr*, 61 (1935) 1003 (H R)

Sedozym (Chemisch Pharmazeutische A G Bad Homburg Frankfurt a M) is a dry vitamin containing yeast extract with 50% calcium and ammonium bromide. It is used as a sedative—*Deut Med Wochschr*, 61 (1935) 1003 (H R)

Septicemine (Laboratoires Cortial Paris) is a crystallized combination of urotropin with iodine and benzometbyl (methyl benzoate?). It contains 33% iodine. It is found on the market in ampuls of 4 cc containing a 10% solution, in tablets of 0.2 and 0.5 Gm and in drops. Septicemine is employed in acute infections, influenza, broncho pneumonia, septicemia etc. The injections are administered intravenously or intramuscularly—*Pharm Weekblad*, 72 (1935), 733 (E H W)

Silver-Col (McKesson & Robbins Inc, Bridgeport, Conn) contains 0.8% eucalyptol, 0.15% silver abietate dispersed in liquid petrolatum 80-85 Saybolt at 100° F. It is claimed to be a highly germicidal colloidal organic silver compound. It is indicated in the prophylaxis and treatment of specific urethritis, congested conditions of the nasopharynx, in gynecology for topical application and urethral instillation, also for skin infections. In scabies a single application with friction preceded by a warm bath usually effects a cure. Sarcoptol is supplied in 2 oz and 4 oz bottles — *Quart J Pharm Pharmacol* 5 (1935) 320 (S W G)

Say-Skin (The Dork Co Cleveland Ohio) is a protective ointment composed of zinc hydroxide cream. It is used as a protection against irritating substances such as liquids fumes or dusts helpful in the prevention of industrial dermatitis. It is supplied in 4-oz and 1 lb jars — *Drug Circ* 79 (July 1935) 40 (T G W)

Scalloral (Asta A G Chemische Fabrik Brackwede) is a cardiac substance obtained from *Bulbus scilla*. It is supplied in capsules liquid and suppository form — *Deut Med Wochschr* 61 (1935) 1003 (H R)

Sedozym (Chemisch Pharmaceutische A G Bad Homburg Frankfurt a M) is a dry vitamin containing yeast extract with 50% calcium and ammonium bromide. It is used as a sedative — *Deut Med Wochschr* 61 (1935) 1003 (H R)

Septicemine (Laboratorios Cortid Paris) is a crystallized combination of urotropin with iodine and benzomethyl (methyl benzoate?). It contains 33% iodine. It is found on the market in ampuls of 4 cc containing a 10% solution in tablets of 0.2 and 0.5 Gm and in drops. Septicemine is employed in acute infections influenza broncho pneumonia septicemia etc. The injections are administered intravenously or intramuscularly — *Pharm Weekblad* 72 (1935) 753 (E H W)

Silver-Col (McKesson & Robbins Inc Bridgeport Conn) contains 0.85% eucalyptol 0.15% silver acetate dispersed in liquid petrolatum 80-85 Saybolt at 100° F. It is claimed to be a highly germicidal colloidal organic silver compound. It is indicated in the prophylaxis and treatment of specific urethritis congested conditions of the nasopharynx in gynecology for topical application and urethral instillation also for skin infections. It is marketed in 2 oz bottles — *Drug Circ* 79 (July 1935) 62 (T G W)

Sodium Racemic Lactate (Parke Davis & Co Detroit Mich) is a molar solution of sodium racemic lactate, a chemical found by Hartmann and Senn to be of distinct value in the correction of acidosis and for the alkalinization of the urine. It may be sterilized either by boiling or by autoclaving. It is administered intravenously intraperitoneally or subcutaneously and may also be used orally. It is supplied in 10 cc ampuls in packages containing 1.6 and 25 ampuls — *Am Drug* (Feb 1935) 106 (T G W)

Soricin Sclerosing Solution (Wm S Merrell Co, Cincinnati, Ohio) is a solution composed of 5% Soricin Merrell (sodium ricinoleate 97 to 98% with minute quantities of sodium oleate and sodium linoleate) in distilled water. The pH of the solution is adjusted to approximately 8.0 to assure a stable chemical compound which may be relied upon to produce uniform clinical results in sclerosing varicose veins, a powerful hemolyzing agent forming a soft gelatinous clot which effectively but slowly organizes obliterating varicosities, when introduced into the vein it causes formation of a soft jelly like thrombus which adheres to the lining of the vein resisting resolutions and absorption, thus an effective obliteration of the vein is produced. It is supplied in 20 cc puncturable cap vials—*Drug Circ*, 79 (July 1935), 28 (T G W)

Sulisocol (Drug Products Co, Inc, Long Island City, N Y) is the trade name for "Hypo sols" or (ampuls) containing a clear sterile aqueous isotonic solution of colloidal sulphur. The solution contains 1% of colloidal sulphur. It is administered intravenously or intramuscularly for the treatment of various forms of arthritis and of certain abnormal dermatological conditions. It is supplied in packages of 25 and 100, 1- and 2 cc ampuls—*Am Drug* (Mar 1935), 106 (T G W)

Sulphocide (The Columbus Pharmacal Co) consists of soluble alkaline polysulphides with betanaphthol and aromatics in a special liquid soap. It is used as an antiseptic solution for the prevention and eradication of certain fungus and parasitic invasions. It is supplied in 3 oz bottles—*Drug Circ*, 79 (June 1935), 70 (T G W)

Thiobisarsol (Christina Laboratories, New York, N Y) is composed of the sodium salt of a bismuth derivative of pentavalent organic ester of aminosulphone arsonic acid containing approximately 36% bismuth and 13% arsenic. It is claimed to prevent leucopenia, to cause a rapid disappearance of the treponema from primary and secondary specific lesions. It is used intramuscularly in the treatment of primary, secondary and tertiary syphilis. It is supplied in boxes of 24 and 100, 2 cc ampuls—*Drug Circ*, 79 (July 1935), 62 (T G W)

Thioglycerol Solution I 50 (Abbott Laboratories, North Chicago, Ill) is a solution of 1 part by weight of thioglycerol in 50 parts by volume of glycerin. It stimulates the growth of epithelial tissue, causes lymph to flow outward toward the wound, produces granulation and epithelial proliferation. It is used in sluggish wounds, due to burns, lacerations or other traumata, varicose ulcers, bed sores, skin grafting. It is issued in boxes of six, 5 cc bottles and bottles of 50 cc—*Drug Circ*, 79 (June 1935), 24 (T G W)

Triglucon (McNeil Laboratories, Philadelphia) is the trade name for capsules representing a combination of iron, copper and calcium gluconates. Each capsule contains 0.032 Gm of iron, 0.00064 Gm of copper plus a sufficient quantity of calcium gluconate. It is an effective alternative and tonic for use in simple and nutritional anemias. It is supplied in both capsules and tablets in bottles of 100, 500 and 1 000—*Am Drug* (Apr 1935), 103 (T G W)

Urginin (The Calco Chemical Co, Inc, Bound Brook, N J) is a mixture of two non-water soluble glucosides, scillonin-A and scillonin B, derived from squill. Each tablet contains 0.5 mg and each cc of solution contains 1 mg. Its cardiac action is essentially similar to that of digitalis. It is useful in cardiac decompensation, in the cardiac arrhythmias in cardiorenal edema. It is issued in bottles of 100, 500 and 1 000 tablets and in solution in bottles of 1 oz, 6 oz and 12 oz—*Drug Circ*, 79 (July 1935), 29 (T G W)

Urinne (Rathkamp Company of Batavia) is the name given to a mixture of vegetable drugs used in the treatment of catarrh of the bladder, kidney and bladder stones. What these East Indian drugs are is not stated. Dr J Blomberg, The Hague, is the Netherlands agent—*Pharm Weekblad*, 72 (1935) 753 (E H W)

Verodigen (C F Boehringer and Sons, Mannheim) is a digitalis preparation. It comes on the market in 0.8 mg ampuls corresponding to 0.1 Gm digitalis leaf. Previously Verodigen was only obtainable in tablet form due to the fact that the solution does not keep well. In the new package it occurs in powdered form 1 cc 0.8 mg of Verodigen mixed with 100 mg of glucose. Beside this an equal number of ampuls of double distilled water are enclosed in which the powder may be dissolved just previous to the injection—*Pharm Weekblad*, 72 (1935) 753 (E H W)

Vibeta (Dr Georg Henning, Berlin) is a preparation which is claimed to contain vitamin E. In 1926 Evans and Burr demonstrated that a diet of food free from vitamin E resulted in sterility. They therefore assumed the presence of an antisterility factor which they named vitamin E. One of the richest materials in vitamin E was wheat germ oil. The administration of this oil to women

subject to having miscarriages appeared to result in a favorable reaction. The firm of Dr G Henning has a similar preparation on the market which was investigated by P Schoorl in the laboratory of Prof Grijns at Wageningen, and in which no antisterility factor could be demonstrated.—*Pharm Weekblad*, 72 (1935) 754 (E H W)

Virapalme (Dr I Donath, Pressburg) is an ointment containing bee poison. It comes in two strengths, normal and forte and is used in the treatment of rheumatism.—*Pharm Weekblad* 72 (1935) 751 (E H W)

Vireysate (Fruit Bischoff Co Inc New York N Y) is a dialysate of *Viscum album* (Mistletoe). It is claimed to be a vasodilator acting upon the small blood vessels and thereby permitting easier circulation. It reduces high blood pressure without disturbing digestion or the nervous system. It also gives relief in *angina pectoris* and may be used prophylactically. It is applied in bottles of 30 cc and in bottles of 25 and 50 tablets.—*Drug Circ* 79 (July 1935) 60 (T G W)

Vistonic Syrup (La Synthe Chimique, Vienna, 16th dist) contains copper chlorophyll, iron and manganese glycerophosphites, quinine, caffeine and extract of strychnine, put up in packages of 115 Gm.—*Pharm Presse* 10 (1935) 279 (M F W D)

Vistonic Tablets (La Synthe Chimique, Vienna, 16th dist) contain copper chlorophyll, iron and manganese glycerophosphites, quinine, caffeine and 0.0025 Gm extract of strychnine per tablet, put up in packages of 20 tablets.—*Pharm Presse* 10 (1935) 279 (M F W D)

BACTERIOLOGY

Antimeningococcic Serum. Protection of Mice against Meningococcus Infection by Polyvalent. Mice were injected with suspensions of meningococci (0.5 cc / 20 Gm) to find several virulent strains. These strains were then used to test the efficacy of various sera. It was found that intravenous injection of serum was no more efficient than intraperitoneal, so the latter method was used. The sera were most efficient when injected (0.5 cc) 1 hour previous to intraperitoneal injection of the meningococci. Ordinarily high agglutinating power corresponded to high bactericidal power of the serum, but not always. Many of the polyvalent commercial sera gave good protection even in dilutions of 1:100. Several experimental antitoxins also gave good protection. Normal horse sera showed great variation but were not effective when diluted. Serum E, which was 5 years old, was the least effective. Tables references.—S F BRANNAN *Pub Health Repts* 50 (1935) 765 through *Squibb Instr Bull* 8 (1935) 1933

Antistreptococcic Serums—Application to, of a New Method of Titration by Neutralization of the Antibodies in Vitro. The use of animals for the titration of streptococcus serums presents several difficulties. Some samples isolated from human infections frequently lose their pathogenic power on animal experimentation. Animals show varying power of resistance and the problem is further complicated by the existence of multiple races of antigens. The authors have applied their principle of finding the maximum volume of serum which is deprived of its antibodies by a known weight of dry antigen. Varying volumes of serum are placed in contact with a constant weight of streptococcal antigen and the presence of liberated antibodies is detected by the precipitation produced by a streptococcal extract. The method is similar to that employed with pneumococcal serum (*Compt rend*, 200 (1935) 2039). Results obtained by this method compared favorably with those obtained on rabbits *in vivo* and permit the foreseeing of the activity of the serum and the survival of the course of the immunization with animals.—LOUIS COTONI and JACQUES POCCION *Compt rend*, 201 (1935) 100 (G W H)

Bacterial Cells—Microscopic Method of Distinguishing Dead from Living. Neutral red was used in distinguishing microscopically between dead and living cells. Cells of *Escherichia coli*, *Schizosaccharomyces pombe* and a yeast isolated from ale were considered dead whenever the cytoplasm proper was tinged even slightly with stain. The concentration of neutral red varies with the organisms. In the case of *Escherichia coli* a concentration of 0.005% was adopted. This concentration is harmless even to the youngest and most sensitive cells and the organism grows readily in broth containing neutral red in that concentration.—GEORGES KNAYSI *J Bacteriol*, 30 (1935) 193 (A H B)

Bacteriophage—I. Studies on the Nature of Bacteriophage can apparently be extracted wholly or in part unharmed from aqueous solutions by ether. The rate and completeness of extraction are influenced by agitation and by time. Unless there is a prolonged period of contact

some bacteriophage remains in the water phase. This residual bacteriophage may be restored to the original potency by serial transfer.—J D LEMAR and J T MYERS *J Infect Diseases*, 57 (1935), 5 (A H B)

Bacteriophage—II Studies on the Nature of Incubation, autoclaving, secondary incubation and oxidation of bacterial broth cultures by hydrogen peroxide yielded lytic filtrates, gave good results when such organisms as *E. coli*, *E. typhosus*, *S. enteritidis* and *Staphylococcus aureus* were grown in broth for forty eight hours, autoclaved twenty minutes at 15 lbs pressure, again incubated for forty eight hours at 37° C and oxidized for forty eight hours at 37° C by 15 cc of 3% hydrogen peroxide. The lytic agent could be removed from water by extraction with ether. It was filterable and transmissible in series. It produced plaques on solid media.—J D LEMAR and J T MYERS *J Infect Diseases* 57 (1935), 11 (A H B)

Bacteriophage—Use of, in the Treatment of Urinary Infections Wehrbein's experience with the technique of phage application showed that the phage must be absolutely and quickly effective before it is used. It should lyse a billion microorganisms per cc in 3-5 hours and prolonged incubation should show no second growth. The phage should be placed in as large a quantity and in as concentrated a form as possible in the infected area. If the kidney pelvis is infected the pelvis should be actually filled with the phage solution. If the bladder only is infected at least 50 cc should be placed into the empty bladder. All antiseptics must be avoided. If the first application of the phage is unsuccessful it is useless to repeat. Of the 34 cases treated by phage and followed completely 10 were acute pyelitic cases and of these 7 were cured through 1 application. The other 3 were improved but not cured. Of the 24 chronic and subacute cases of pyelitis only 5 were cured 13 were benefited and 6 were failures. An appendix by Louis Nerb concerns the preparation of phages. Bacteriophages produced by heat were found to have a higher titre and be more potent than that produced by cold.—H L WEHRBEIN *Am J Surg*, 29 (1935) 40, through *Squibb Abstr Bull* 8 (1935), A 993

Bacterium Typhi Flavum—Study of the So-Called The results of a study of 19 strains of the so-called *Bacterium typhi flavum* are given. It is suggested that any relation of the *Bacterium typhi flavum* to enteric infections is unproved and that its appropriate place is in the genus *Chromobacterium*.—J C CRUICKSHANK *J Hygiene*, 35 (1935) 354 (A H B)

Chloramine-T and Calcium Hypochlorite—Some Observations on the Germicidal Efficiency of The reduction in killing time was about 55% for each doubling of the concentration of Chloramine T. The pH range studied was from 6.0 to 8.8, and it was found that increasing the acidity markedly reduced the killing time. "Available chlorine" was not found to be a direct measure of the germicidal efficiency of the calcium hypochlorite studied.—D B CHARLTON and M LEVINE *J Bacteriol*, 30 (1935), 163 (A H B)

Cholera Group of Vibrios—Antigens of By preparing the serum with suspensions boiled or steamed for 2 hours to destroy the common H antigen, bacteriological proof of "cholera" or a cholera carrier should rest on the isolation of a non hemolytic vibrio with the specific O antigen of subgroup I.—A D GARDNER and K V VENKATRAMAN *J Hygiene*, 35 (1935), 281-82 (A H B)

Colds—New Explanation of The fact that outdoor workers, seamen and arctic inhabitants rarely have colds has led practitioners to doubt the influence of cold on sickness. F Munk has shown that there is a difference in potential between the nasal mucous membranes and the moistened palm of the hand, and that exposure of the feet to cold lowers the potential difference. Since all organisms have an electrical biological optimum and minimum, and since various irritations reduce the potential of the mucous membranes of the air passages the virulence of the organisms is allowed to increase thus beginning infections.—J B L. *Schweiz Apoth-Ztg* 73 (1935), 369 (M F W D)

Diphtheria Antoxin—Purification and Concentration of Sodium 7 amino 1,3,6 naphthalenetrisulphonate and citric acid at about pH 4 rapidly and completely precipitated the active principles of diphtheria toxin and antoxin, and allowed recovery in a purified and concentrated condition of about 75% of the original toxin and 95% of the original antoxin.—H GOLDBERG *Compt rend soc biol* 119 (1935), 518, through *Squibb Abstr Bull* 8 (1935) A 924

Diphtheria Cultures—Culture Media Used for Routine with a Suggested Modification of Loeffler's Blood Serum Medium Media used should be of a composition and reaction which would support luxuriant growth and permit the development of what are termed "typical forms"

of *C. diphtheriae* to facilitate the examination of cultures. *S. aureus* produces sufficient acid from the dextro component in Loeffler's medium in 18 hours to influence greatly the luxuriance of growth, morphology and staining of *C. diphtheriae*. The following formula gives a more typical and more luxuriant growth of *C. diphtheriae* in mixed throat cultures than Loeffler's blood serum.

Hog or human serum	800 cc
Glycerol	40 cc
Sodium sulphide (sodium monosulphide) dissolved in 10 cc of cold water	1.50 Gm
Bouillon concentrate	1.60 cc
Bouillon concentrate —	
Protein & peptone	1.25 Gm
Dipotassium phosphate	1.25 Gm
Cystine	0.5 Gm
Water	160 cc

Requires from 5 to 10 cc of normal sodium hydroxide solution per liter of the mixture — ROSS L. LAYBOURN. *Am J. Pub. Health* 25 (1935) 796. (A H B)

Diphtheria Toxin. Skin Reaction of. The cutaneous reaction to pure diphtheria toxin was used to determine susceptibility to diphtheria. The test did not always correspond with the routine Schick test and it was a little hard to be sure of a positive reaction — G. ANDRIEU and A. FOURNAIR. *Compt. rend. soc. biol.* 119 (1935) 15, through *Squibb Inst. Bull.* 8 (1935) A 924.

Disinfectants. Testing of, in the Presence of Organic Matter. This paper develops a method in which a suspension of yeast is used for testing disinfectants which introduce faces as added organic matter and causes an equivalent reduction in disinfectant activity and yields consistent results — I. P. GARROD. *J. Hygiene (British)*, 35 (1935) 219. (A H B)

Ergot Cultures, Saprophytic.—Alkaloidal Content and Activity of. Ergot cultures were grown by inoculating various nutrient media with the fungus mycelium and the alkaloidal content of the artificial cultures was then studied in relation to the character of the medium, pH and influence of light. The nutrient medium here consisted of 2% agar with 0.1% monopotassium phosphate and 0.02% magnesium sulphate. Its composition was varied in the proportion of carbohydrate and protein by the addition of 10% dextrose, 5% maltose, 5% mannitol and (or) 1% asparagine, 3% gelatin, 2% peptone and 1% leucine. The alkaloidal content of the different cultures was determined colorimetrically by the use of *p*-diethylaminobenzaldehyde. The influence of light on alkaloidal content was negligible but variations in the composition of the nutrient media caused wide fluctuations in alkaloidal content. Leucine proved of little value as a source of protein. The combinations dextrose-leucine and maltose-leucine produced cultures of very low alkaloidal content. Germination did not occur on mannitol-leucine medium. Peptone gave good results in combination with all three carbohydrates especially with maltose. Of the carbohydrates maltose gave the best results in any of the combinations studied. In general, well developed cultures possessed high alkaloidal contents but the parallel between alkaloidal content and mycelial growth did not apply in all cases, an exception being found in the combination dextrose-asparagine. The alkaloidal contents estimated by the Broom-Clark method were not in agreement with the values obtained by the colorimetric method — R. JARETZKY. *Arch. Pharm.* 273 (1935), 348. (L L M)

Extra-Bacterial Substances in Cultures.—Production of. On saccharose media bacteria of the subtilis group produce abundantly a non-stainable extra-bacterial substance capable of multiplication without intervention of bacteria. The extra-bacterial substance spreads out from the subtilis colonies on the surface of nutrient agar plates forming a halo around the colonies. The properties of the extra-bacterial substance and the growth phenomena, especially the extension of the halo on the agar surface, strongly suggest that the extra-bacterial substance contains living organisms. Morphological observations give further support to this conclusion — L. DIENES. *J. Infect. Diseases*, 57 (1935), 44-45. (A H B)

Extracts of Drug Plants.—Action of Aqueous, on Bacterium Coli and Aspergillus Niger. Extracts of 46 plants were examined. The freshly powdered plant was extracted 1 hour with water at 50° C (1 part of plant and 2 parts of water). The extracts were filtered, the pH determined, germ content and action toward *B. coli* and *aspergillus* determined. The plant residues were ob-

served as to the manner of the decomposition. The germ content was determined as follows: Mix 1 cc of the extract with standard II Nahr agar (Merck) in a petri dish and with the aid of a Wollugel plate count the organisms after 24 hours (37° C), repeat the count after an additional 24 hours. Results show extracts in which the number of organisms decreased rapidly after 24 hours, in many the growth was strongly retarded, in most cases many organisms were present, a few became sterile after days or weeks, a few putrified and the majority molded. As a rule the p_H of the extract decreased sharply. *The Action of the Plant Sap on B. coli*—5 cc of the extract was kept with 1 drop of a 24 hour bouillon culture of *B. coli* for 48 hours at 37° C and then at room temperature. The control tubes contained 5 cc bouillon and 1 drop of culture. A dilution series of 2.5 cc of extract plus 2.5 cc bouillon and 1 drop of culture was treated in the same manner. Sterilized ($\frac{3}{4}$ hour at 100° C) and non sterile extracts were so treated. The tests showed that after some days, and in a few cases weeks, a great portion of the extracts (33) were sterile. In no case can any relationship between p_H and sterility be revealed. The death of the organisms apparently is due to definite plant constituents. *Aspergillus niger*—In like manner the action on these spores was studied. From a thriving culture on a beer yeast agar slant was prepared a suspension with physiological salt solution. To 5 cc (or a dilution of 2.5 cc + 2.5 cc) of the plant extract was added a drop of the spore suspension. The tubes were incubated as before. Only a few extracts hindered the growth of the spores.—H SCHINDLER and T MÖBUS *Apoth.-Ztg.*, 50 (1935), 559-561 (H M B)

H. Pertussis—Phases or Types of By absorption and agglutination tests *H. pertussis* is a uniform species without any type variations. It has, however, different phases of existence as shown by absorption phenomenon.—J A TOOMEY, K RANTA, L ROBEY and J E McCLELLAND *J Infect Diseases* 57 (1935), 56 (A H B)

Immunizing Preparations Antibodies are obtained from human or animal urine during convalescence from infectious diseases. The urine (after filtration and dialysis) may be treated with an albumin precipitant, e g, lead subacetate, phosphotungstic acid, mercuric chloride, sulphosalicylic acid, formalin, alcohol, or ammonium sulphate, and the antibodies recovered from the precipitate, or the antibodies may be extracted from the urine by absorbents, e g, aluminum hydroxide, kaolin, Fuller's earth, silica gel, calcium carbonate or calcium phosphate, or urine, after extraction with ether or similar solvent to remove impurities, may be concentrated or mixed with an inert medium and dried. Precipitates made with heavy metal salts are treated with hydrogen sulphide to remove said metals and the remaining solution may be further purified by dialysis, precipitates made with other than heavy metal salts are dialyzed to remove the precipitants and the remaining solid is extracted with sodium chloride solution or weakly alkaline Ringer solution to yield the antibody.—G MADAUS, F MADAUS and H MADAUS (trading as Madaus & Co) *Brit Pat* 423 883 (Feb 11 1935), through *Chem Abstr.*, 29 (1935), 4525

Indole—Bacteriostatic Action of, on Gram-Negative Enteric Bacilli and on Certain Cocci Small amounts of indole inhibited the growth of many enteric bacilli. Its effectiveness varied greatly with different species and even with different strains of the same species, but not appreciably for individual cultures on repeated tests. The indole content of intestinal material may play an important role in determining the character of the intestinal flora. Members of the Escherichia Aerobacter group and both *Staph aureus* and *Staph albus* were equally resistant, while some of the bacilli and some of the cocci were equally sensitive.—R P TITSLER and L A SANDHOLZER *J Infect Diseases* 57 (1935) 68 (A H B)

Koch's Phenomenon—The Production of, with Various Strains of Tubercle Bacilli In tuberculous animals intracutaneous injection of dissociated strains of tubercle bacilli (R and S forms) produced Koch's phenomenon, which is a marked necrosis, in a definite and uniform manner. Animals with generalized tuberculosis R strains, excited in the majority of cases an intense Koch's phenomenon while S strains either failed to produce the phenomenon or produced it only in an atypical form.—W PAGEL *J Pathol Bacteriol* 41 (1935), 95 (A H B)

Oxybenzoic Acid Esters—Researches with, for Sterilization of Eye Drops Various eye drop solutions were prepared using as the diluent a 0.05% solution of Nipazol (propyl ester of *p* oxybenzoic acid). The solutions were transferred to sterile glass stoppered bottles. The solutions were sterile after preparation. Each of the eye solutions was then inoculated with a loopful of cultures of *Pyogenes aureus*, *Bacterium coli* and *Aspergillus Art*. At intervals 1 cc of the eye solution was plated on about 10 cc of nutrient bouillon and incubated. In one to three days the

solutions were found to be sterile again. No spore bearing cultures were used. A series run in the same manner using a 0.2% solution of Nipagin (methyl ester of *p* oxybenzoic acid) were sterile within 21 hours. A series of the same eye drops inoculated with suspensions of *Mesentericus* and *Aspergillus* spores was not sterile after 14 days. Another series of eye drops was prepared using a 0.1% and a 0.15% solution of Nipagin Sterilisator I (a combination of *p* oxybenzoic acid esters) and each of the sterile solutions inoculated with spore bearing material as above. After 14 days at room temperature the solutions were not yet sterile. A second series prepared exactly the same but sterilized in steam at 100° for 30 minutes was sterile in all cases. A 0.3% solution of 'Nipagin Sterilisator I' and 30 minutes steam at 100° merely inhibited but did not destroy native earth spores. More extensive work must be carried out to determine whether the combination of heat and Nipagin Sterilisator I affect injuriously other medicaments used in eye solutions.—J. THOMAS. *Pharm Acta Helv* 10 (1935) 103. (M F W D)

Pleuro-Pneumonia Contagiosa Boum—Study of the Morphology and Life Cycles of The causil organism of *pleuropneumonia contagiosa boum* is not a filterable virus *sensu stricto* but typically and constantly forms a relatively enormous briney mycelium which owes its filterability to the constant and early production of filter passing forms (condioids), with polygenethodism, extreme pleomorphism and a protean faculty of rapidly changing its shape.—A. W. TURNER. *J. Path. Bacteriol* 11 (1935) 29. (A H B)

Pneumococcus Solubility of, in Saponin. With saponin in 1:20 concentration, and cholesterol in 1:5000 to 1:500000 concentration lysis often appears within a few minutes and is usually complete within thirty minutes at room temperature. The bacterial suspension becomes completely clarified and transparent. No intact bacteria are to be found on microscopic examination in the case of complete lysis. S. J. KLEIN. *J. Bacteriol*, 30 (1935) 47. (A H B)

Rocky Mountain Spotted Fever Results of Ten Years' Prophylactic Vaccination. Preparation of Rocky Mountain fever vaccine makes use of the virus laden adult Rocky Mountain wood ticks which after feeding for three to five days on guinea pigs are sterilized exteriorly. They are then thoroughly comminuted mechanically with sterile sand in lots of 500 in a small amount of physiological salt solution containing either 2% of phenol alone or the same percentage of a phenol formalin mixture. After grinding sufficient of the preservative is added to bring the total volume to 100 cc. In seven days 300 cc of physiological salt solution is added and the product centrifuged to throw down the tick tissue and sand. The resultant supernatant fluid is the vaccine. No method of potency standardization has been devised. It is considered usable if four of six guinea pigs that receive 1 cc each are fully protected against a subsequent injection of 1 cc of guinea pig passage virus (blood). The recommended minimum dosage is two injections of 2 cc each for adults.—R. R. PARKER. *J. Infect. Diseases* 57 (1935) 78. (A H B)

Scarlet Fever Toxin and Antitoxin—Testing of, by the Rabbit Intradermal Method. This paper describes a method of titrating scarlet fever toxins and sera on the skin of rabbits with mixtures of toxins and antitoxins which are heated to 50° C for two hours and injected intradermally into rabbits the test proving reliable within a 1:2 ratio. A pre injection given intravenously with a small quantity of an antitoxic serum a day before the intradermal injections improves the reactions and the number of animals which fail to give readings is reduced.—G. A. H. BUTTLE and A. S. R. FOWDEN. *J. Path. Bacteriol* 41 (1935) 115. (A H B)

Skatole—Bacteriostatic Action of, on Gram-Negative Enteric Bacilli. It is evident from the results of this study that small amounts of skatole from 1:3000 to 1:6000 inhibited the growth of gram negative enteric bacilli. The average antiseptic potency of skatole is approximately twice that of indole.—R. R. TITSLER, L. A. SANDHOLZER and E. T. CALLAHAN. *J. Infect. Diseases* 57 (1935) 57. (A H B)

Smallpox and Diphtheria—Simultaneous Immunization against. The simultaneous immunization against diphtheria and smallpox is a practical, effective and safe procedure.—CHARLES S. STERN. *Am. J. Pub. Health* 25 (1935), 1035. (A H B)

Staphylococcus Toxin Toxins of high lytic activity were obtained by growing certain strains of *staphylococcus* in an atmosphere of 10–24% carbon dioxide. The toxin dissolves blood and tissue cells, coagulates plasma and dissolves fibrin. It has high antigenic qualities.—J. TRAVASSOS. *Memorias Butantan* (S. Paulo), 8 (1933–1934), *Rev. sud americana endocrinol. immunol. quimioterapia*, 18 (1935), 442–443. (A E Meyer)

Sterility—Visible Test for. As the result of work by G. Gosio and others in the (Italian)

Public Health Laboratories it was shown that schizomycetes when growing in a medium containing minute amounts of tellurium or selenium, although usually colorless, develop a reddish or brownish black tint according to whether selenium or tellurium is present, owing to the reduction of their respective compounds. Further investigation showed that with selenium this might occur through the action of the medium but with potassium tellurite on all the ordinary culture media (broth or agar, with glucose or with glycerin) there was never any reaction in the absence of bacterial life. This was therefore put into practice in the case of leicithin preparations, vaccines and opotherapeutic products, since it is impossible to be sure, by the ordinary methods, that, for example, every ampul in a batch is sterile. In the presence of potassium tellurite a brown color shows definitely the growth of bacteria and the development of no color shows that the preparation is safe. This test has been in use for 25 years with invariable success, and it has the great advantage that the patient or the doctor can see at once if the preparation is unfit for use.—NEPPI *Therapia* (Dec 1934), through *Quart J Pharm Pharmacol*, 8 (1935), 289 (S W G)

Tetanus Antitoxin—Persistence of, in Man In a group of twelve persons, the tetanus antitoxin level, persisting two years after a primary series of three doses of tetanus toxoid, did not fall appreciably during the last year. A secondary stimulus of 1 cc of toxoid given to these persons within a week effected a definite increase in titre, which persisted at significantly high levels after a month. Antitoxin titres similarly attained in a previous group are shown to persist after a year at or above the level of 0.1 unit per cc of serum in nine of the total group of ten persons.—P A T SNEATH and E J KERSLAKE *Brit Med J*, 3893 (1935), 290 (W H H)

Typhoid Fever Vaccine—Effectiveness of, in Control of Typhoid Fever Analysis of the incidence of typhoid fever for several years, in the army, navy and several communities compared with the incidence of typhoid vaccination has shown that typhoid vaccine offers a very considerable protection against typhoid infection and is a useful adjunct to a sanitation program, but that it cannot be relied upon to protect against mass infection nor grossly unsanitary conditions. In the discussion following the paper, it was revealed that the vaccine given after exposure to the disease, decreases the severity and duration of the infection, and that the tendency is away from mixed vaccines. Paratyphoid A does not occur in the U S and paratyphoid is a relatively mild infection so that there is no advantage in the use of combined paratyphoid A and B and typhoid vaccine.—R W TODD *New Orleans M and S J* 88 (1935), 30, through *Squibb Abstr Bull*, 8 (1935), A-1016

Whooping-Cough—Control of, with Serum and Vaccine Convalescent serum from cases of whooping cough has been used with definite benefit in the prophylaxis, but doubtful in the treatment of pertussis. A preliminary description is given of a skin test which can be used both to diagnose whooping cough in an early stage, and also to pick out those children who are susceptible to the disease. The pertussis skin test is further evidence that children can be immunized against whooping-cough by the giving of a suitable vaccine. Children who give a negative skin test can be made to give a positive skin test by the injection of the vaccine.—D PATERSON R H BAILEY and R G WALLER *Lancet*, 49 (1935), 361 (W H H)

BOTANY

Anthracene Oils Used for the Defence of Crops A general discussion of the physical and chemical characteristics of anthracenic tar oils, of their insecticidal action and of their possible harmful action on plants.—M RAUCOURT *14me Congrès de Chimie Industrielle, Paris*, Oct 21-27 1934, 6 pp (A P-C)

Brazilian Flora—Mydriatics and Myotics from Various native plant drugs are enumerated and described for both external and internal application.—F W FREISE *Suddeut Apoth-Zig*, 75 (1935), 333, through *Chem Abstr*, 29 (1935), 4519

Cinchona Plant in Russia According to some authors *Cinchona succirubra* at an age of two and a half years contains 4.083% and at an age of 3 years 4.121% of quinine. According to other authors *Cinchona ledgeriana* at an age of 1 year contains 2.18% of quinine and 2.64% of other alkaloids, at an age of one and a half years it contains 4.49% of quinine and at an age of 2 years 5.15% of quinine. Some authors have stated that the quinine content of very young plants may be equal to 6%. A series of experiments was carried out in various regions of Southern Russia with various types of cinchona and the quinine content obtained from these plants gave an average

of about 2% of quinine. On the basis of the results obtained the author hesitates to state whether the culture of cinchona in Russia is justified.—G K KIRK *Soviet Pharm* 3 (1935) 19

(A S)

Digitalis—Proportion of Digtioxin in *Digitalis* was cultivated at Valperga and gave plants of medium size, the second year leaves averaging 25 cm by 7 to 10 cm. When sections were treated under the microscope with a mixture of one drop of picric acid solution and one drop of 10% sodium hydroxide, in two minutes the orange color developed by the cells containing the glycosides could be observed. A quantity of liquid extract was prepared according to the Italian Pharm and the digtioxin was estimated by the method therein described. It contained 0.22% the Pharm requirement being 0.20%.—I. BERTONASCO *Boll chim farm* 74 (1935), 114 through *Quart J Pharm Pharmacol* 5 (1935) 255

Vermifuge Grains of the Combretaceae of Madagascar A botanic history and a botanic and histologic description of the leaves and fruit of *Ouvagualis indica* L. are given.—L. MAHER and R. WILTZ *Bull sci pharmacol* 12 (1935) 202

(C T I)

Ylang Oils—Classification of Commercial The botanic source of ylang ylang oil and of its poor relation cananga oil is *Cananga odorata*, a tree which is widely cultivated in certain parts of tropical Asia. The tree attains a height of 60 feet or more. Of recent years the French growers in Reunion have introduced the practice of stopping the growth to produce a smaller tree from which the flowers can be more easily picked. It is propagated by seedlings. Growth is rapid and by the third year a crop of the beautifully perfumed yellowish green flowers is obtained. These flowers must be allowed to ripen to a full yellow color to develop their full fragrance before being picked. This may take 20 days. Commercially the oils from *Cananga odorata* fall into three main types: Manila ylang, Bourbon ylang, and cananga. Each oil is discussed.—F. ATKINS *Perfumery Essent Oil Record* 26 (1935) 251

(A C DeD)

CHEMISTRY

CHEMICAL AND PHYSICAL

Aluminum Subacetate—Molecular Solubility of The literature shows great disagreement on the question of the kind of solution formed by aluminum subacetate. Some hold it forms true solutions, others insist that colloidal solutions are formed. From conductivity and freezing point depression measurements the author concludes that aluminum diacetate forms a true and not a colloidal solution.—C. ROMMANN *Pharm Ztg* 80 (1935) 493

(G E C)

Glass Electrode—Measurements with the The method of potential measurement employing the glass electrode are reviewed. The types of these electrodes and the various factors influencing the accuracy of determination are discussed. The theories of the glass electrode are considered. Use of the Lindemann electrometer as a null instrument in a compensating circuit is recommended.—G. KILDE *Dansk Tidsskr Farm*, 9 (1935) 129

(C S L)

INORGANIC

Heavy Water—Research on the Content of, in Mineral Waters A series of mineral waters from different medical sources was analyzed. The samples were carefully distilled, and their refractive indices determined to check their purity. The examinations showed that the heavy water content did not differ from that of ordinary water.—K. HANSEN, E. RUSTUNG and J. HVEDING *J pharm chim*, 21 (1935), 538

(M M Z)

Hydrogen Peroxide—Decomposition of, in Presence of Glass Wool and Copper Sulphate The decomposition of a solution of pure hydrogen peroxide in water, filtered free from all dust particles into perfectly dust free quartz containers, is extremely slow, even appreciably alkaline solutions of the order of pH 9. The addition of glass wool increases the rate of decomposition which does not further increase on addition of more glass wool. Copper is adsorbed from dilute solutions of copper sulphate by glass wool, which becomes a greenish color, and the addition of this coppered wool greatly increases the rate of decomposition of hydrogen peroxide. The author gives

figures for the distribution of copper between copper sulphate and glass wool, and states that the decomposition of hydrogen peroxide in the presence of glass wool is a reaction of the first order, whereas that with coppered glass wool is of zero order —K C BAILEY *Sci Proc Roy Dub Soc*, 21 (1935), 153, through *Quart J Pharm Pharmacol*, 8 (1935), 260 (S W G)

Orthophosphoric Acid—Migration Phenomena in the Course of Hydrolysis of the Three Mixed Di-esters Shifting of the α and β Glycerophosphates The difference in yields ($\frac{2}{3}$ and $\frac{1}{3}$, respectively) of the two transpositions which accompany the hydrolysis of the isomeric -methyl and methyl glycerophosphates according to the equation

is explained as follows Although in both cases the same di ester $\alpha \beta$ monoglycerophosphate is formed, it may be formed more readily in the first than in the second case because of a more favorable spatial arrangement —OCTAVE BAILEY and J GAUMÉ *J pharm chim*, 22 (1935), 23–32 (S W G)

Silver-Mercury Complex A solution was prepared containing 10 Gm of silver nitrate, 100 cc distilled water 20 cc nitric acid (d 1.334) and this was added to 200 cc of an aqueous solution containing 15 Gm of mercuric cyanide in 200 cc of distilled water The precipitate formed was filtered washed and dried A study of this compound indicated that it was a complex type Two molecules of water of hydration are retained regardless of the solvent used while both silver nitrate and mercuric cyanide are anhydrous salts The complex is insoluble in ether, yet mercuric cyanide is soluble On addition of sodium hydroxide, there is first obtained a white precipitate (silver cyanide), then a yellow precipitate (basic nitrate of mercury), while silver nitrate alone yields a brown precipitate —J BOUGAULT and E CATTELAÏN *J pharm chim*, 21 (1935), 581 (M M Z)

Sodium Perborate—Note on Official perborate of soda being $\text{NaBO}_3 \cdot 4\text{H}_2\text{O}$ should be a definite chemical substance However a difference has been shown to exist between samples prepared by a French company and those of a Swiss company The Swiss perborate on solution produces a perfectly clear solution, whereas the French perborate gives a solution containing a light flocculent precipitate which eventually settles out Titration of the available oxygen showed no appreciable difference in the two samples Temperature caused both solutions to deteriorate, the French sample being more stable The Swiss perborate under the microscope showed small clear crystals, the French showed opalescent crystals —A MIRIMANOFF *Pharm Acta Helv* 10 (1935) 122 (M F W D)

ORGANIC

Alkaloids

Cinchona Alkaloids—Modified Part II The action of sulphuric acid on quinine and quinidine is reported Two distinct groups of products were obtained apo bases (demethylated or phenolic bases) and isomerides of quinine and quinidine (undemethylated bases) In addition to apoquinine (previously reported), two other bases were obtained *isoapoquinine* [m p 275° , (α) $_{\text{D}}^{15}$ -261.7° ($c = M/40$ in alcohol)] and *hydroxydihydroapoquinine* [m p $281\text{--}284^\circ$ (α) $_{\text{D}}^{15}$ -205.4° ($c = M/40$ in $N/10$ sulphuric acid)] The former was obtained in the mother liquors of the acid sulphate obtained in the process of purification of apoquinine The latter is produced when pure apoquinine is boiled with 60% sulphuric acid From quinidine, in addition to *l*-iso apoquinidine (previously reported), the authors obtained *apoquinidine* [m p 172° (α) $_{\text{D}}$ $+208.6^\circ$ ($c = 1$ in alcohol)] and a third isomeride provisionally named *base A* No hydroxydihydroapoquinidine analogues with the apoquinine product were isolated The undemethylated bases recovered from quinine so far yielded only one crystalline product [m p $183\text{--}185^\circ$ (α) $_{\text{D}}^{15}$ -201.9° ($c = 0.811$ in alcohol)] identical with apoquinine methyl ether (previously reported) and beta

of about 2% of quinine. On the basis of the results obtained the author hesitates to state whether the culture of cinchona in Russia is justified —G K KRIER *Soviets Pharm* 3 (1935), 19

(A S)

Digitalis—Proportion of Digitoxin in Digitalis was cultivated at Valperga and gave plants of medium size, the second-year leaves averaging 25 cm by 7 to 10 cm. When sections were treated under the microscope with a mixture of one drop of picric acid solution and one drop of 10% sodium hydroxide, in two minutes the orange color developed by the cells containing the glycosides could be observed. A quantity of liquid extract was prepared according to the Italian Phar and the digitoxin was estimated by the method therein described. It contained 0.22% the Phar requirement being 0.20% —E BERTONASCO *Boll chim-farm*, 74 (1935) 114 through *Quart J Pharm Pharmacol* 8 (1935) 285

(S W G)

Sandal—Spike Disease of A review of a series of transmission experiments carried out with the insect fauna associated with healthy and spiked sandal plants. These experiments were carried out since 1931 and new ones are still in progress —ANON *Perfumery Essent Oil Record*, 26 (1935) 305

(A C DeD)

Vermifuge Grains of the Combretaceæ of Madagascar A botanic history and a botanic and histologic description of the leaves and fruit of *Quisqualis indica* L. are given —L MAHEN and R WEITZ *Bull sci pharmacol* 42 (1935) 202

(C T I)

ORGANIC

Alkaloids

Cinchona Alkaloids—Modified Part II The action of sulphuric acid on quinine and quinidine is reported Two distinct groups of products were obtained apo bases (demethylated or phenolic bases) and isomerides of quinine and quinidine (undemethylated bases) In addition to apoquinine (previously reported), two other bases were obtained *isoapoquinine* [m p 275° (α)_D¹⁵ -261.7° ($c = M/40$ in alcohol)] and *hydroxydihydroapoquinine* [m p $281-284^\circ$ (α)_D¹⁵ -205.4° ($c = M/40$ in $N/10$ sulphuric acid)] The former was obtained in the mother liquors of the acid sulphate obtained in the process of purification of apoquinine The latter is produced when pure apoquinine is boiled with 60% sulphuric acid From quinidine in addition to *isoapoquinidine* (previously reported), the authors obtained *apoquinidine* [m p 172° (α)_D $+208.6^\circ$ ($c = 1$ in alcohol)] and a third isomeride provisionally named *base A* No hydroxydihydroapoquinidine analogues with the apoquinine product were isolated The undemethylated bases recovered from quinine so far yielded only one crystalline product [m p $183-185^\circ$, (α)_D¹⁵ -201.9° ($c = 0.811$ in alcohol)] identical with apoquinine methyl ether (previously reported) and beta

isoquinine of Suszko From quinidine, *beta*-isoquinidine [$m p 142^{\circ} (\alpha)_D^{17} -97 (c = 1.4224 \text{ in alcohol})$] which was shown to be isoapoquinidine methyl ether, methyl ether of the new apoquinidine [$m p 181^{\circ}$ —anhydrous crystals from ether $90-100^{\circ}$ —monohydrate in rhombic plates from aqueous acetone, $(\alpha)_D^{15} +193.2^{\circ} (c = 0.7815 \text{ in alcohol})$, the hydrochloride has $m p$ of 267° and $(\alpha)_D^{15} +174.7^{\circ} (c = 0.902 \text{ in water})$] The latter differed from alpha isoquinidine of Domanski and Suszko, particularly in specific rotation A possible third and dextro rotatory isomeride of quinidine was obtained in small yields —T A HENRY W SOLOMON and E M GIBBS *J Chem Soc* (1935) 966-971 (G W F)

Ergot—Active Principles of In experiments involving the use of pregnant cats, the available salts of ergotamine and ergotamine were found to fall far short of being carriers of the full oxytocic activity of ergot The activity of crude pharmacopoeial extracts of the drug is far more prompt and intense, and entirely out of proportion to the alkaloidal equivalents of such extracts when calculated in terms of ergotoxine or ergotamine, thus indicating the existence of a very important hitherto unidentified source of activity This important activity is shown to reside in the "total specific alkaloidal fraction" of the drug Removal of the hitherto known alkaloids from this fraction left the greater part of the oxytocic activity behind The new and more important oxytocic substance was isolated and found to be similar in certain fundamental respects to ergotoxine and ergotamine differing mainly in being much more soluble and absorbable than the well known ergot alkaloids Because of its chemical and pharmacological properties, the newly isolated substance was temporarily designated as "X alkaloid" Its relationship to the results obtained by currently used methods of bioassay received appropriate consideration —MARVIN R THOMPSON *J Pharmacol*, 54 (1935) 161 (H B H)

Ergot—Chemistry and Pharmacology of A review —K W MERZ *Apoth Ztg*, 50 (1935), 472-474, 493-497 (H M B)

Peyote—Alkaloids of The powdered 'mescal buttons' are extracted with 70% alcohol the solvent is evaporated under vacuum, the alkaloids in the residue are liberated by addition of ammonia and extracted first with ether and then with chloroform the solvents are evaporated and the residue is dissolved in water the brown strongly alkaline solution is neutralized exactly with sulphuric acid the precipitated resins are filtered out the filtrate is concentrated and the crystals obtained, consisting of sulphates of mescaline and anhalonidine, are decolorized by bone char, the filtrate is treated with barium chloride and filtered and anhalonine hydrochloride crystallizes in the filtrate The latter is treated with an alcoholic solution of chloride of mercury, the chloromercurate which separates is recrystallized, decomposed by hydrogen sulphide and filtered, the solution is extracted with ether the extract is neutralized with hydrochloric acid, concentrated in vacuum and the oily mass which separates soon crystallizes It consists of the hydrochlorides of peyotline anhalonine and lophophorine which are separated by fractional crystallization —G TOMASO *La Chimica*, 10 (1934) 408-416, through *Chimie et Industrie*, 34 (1935) 138 (A P C)

Physostigmine (Eserine)—Experiments on the Synthesis of Part XI The later phases of synthetic investigations are described One of the more promising methods of synthesizing eserine is *dl* noreserethole \rightarrow *l* noreserethole \rightarrow *l* eseretholemetho salt \rightarrow *l* eserethole \rightarrow *l* eseroline \rightarrow eserine *dl*-Noreserethole on controlled methylation with methyl *p* toluenesulphonate, yielded crystalline *dl* eserethole ($m p 79-80^{\circ}$) It was found that this was identical with product of Hoshino and Kobayashi by direct comparison of specimens The latter authors described their base as $C_{16}H_{21}ON_2$ while King and Robinson found it to be $C_{16}H_{22}ON_2$

FREDERICK E KING and ROBERT ROBINSON *J Chem Soc* (1935), 755-759 (G W F)

Protopine and Allied Alkaloids—Synthetic Experiments on Part II A new synthesis of the berberine ring system and of a ring homologue of the apomorphine alkaloids is reported This is more simple but less flexible than any synthesis previously described I and II are reacted to form

III Thus, when treated with phosphorus pentachloride, produces double ring closure with elimination of water and methyl alcohol and simultaneous dehydrogenation to yield 25% of a berberine analogue (IV)

The compound V, prepared from VI and VII, when treated with POCl_3 produced upon reduction, the substance VIII containing the apomorphine skeleton modified by the presence of an extra methylene group in the central ring

THOMAS S STEVENS *J Chem Soc.*, (1935) 663-667

(G W F)

Quinine, Quinidine, Cinchonine and Cinchonidine—Specific Rotatory Power of the Salts of Addition of hydrochloric acid to these bases forming first the mono- then the dihydrochlorides shows a progressive increase in rotatory power which can be explained on the basis of the ionization of the salts. There are four asymmetric carbons in these bases. It is concluded that quinine and quinidine are epimeric and are identical on carbons 1 and 2 but are optically inverse on carbons 3 and 4. Cinchonine and cinchonidine are identical on 1, 2 and 4 but different on 3. Sterically the methoxyl and the vinyl chains of quinine and cinchonidine can be represented as parallel and in the same direction, while the chains of quinidine and cinchonine are parallel but in the opposite direction. This explains the high antimicrobial activity of quinine, the different properties of the four alkaloids and the well known influence of the modification of the lateral chains on the pharmacodynamic properties.—CHARLES LAPP *Compt rend.*, 201 (1935) 80 (G W H)

Strychnine and Brucine Part XXXIII Methoxymethylchanodihydrostrychnanic acid was found to be resistant to facile dehydrogenation. Likewise methoxymethylchanodihydro-

strychnone was found to be resistant. These reactions indicate the veracity of the formula previously reported for methoxymethylidihydroneostrychnine.—T M REYNOLDS and ROBERT ROBINSON *J Chem Soc* (1935), 935-940 (G W F)

Yohimbine—An investigated commercial yohimbine consisted principally of a base having the same melting point and optical rotation as *iso* yohimbine. The yobyrine which Mendlik and Wibant obtained by dehydrogenation of yohimbine (*Rec des Trav Chim des Pays Bas*, 50 (1935), 91) has the formula $C_{19}H_{16}N_2$ and is identical with that obtained by Barger and Scholz (*Helv Chim Acta*, 16 (1933), 1343). Catalytic hydrogenation of yobyrine $C_{19}H_{16}N$ yields decahydro yobyrine $C_{19}H_{26}N_2$, whereas tetrahydroyobyrine $C_{19}H_{20}N_2$ yields octahydroyobyrine $C_{19}H_{24}N$.—H P WIBANT and A H P VAN GASKE *Rec des Trav Chim des Pays Bas* 54 (1935) 85, through *Pharm Zentralh* 76 (1935) 460 (E V S)

Essential Oils and Related Products

Abies Sibirica—Composition of Ethereal Oil of. The work is summarized by the author as follows. 1 The ethereal oil of *Abies sibirica* studied was found to correspond by its physico-chemical properties to the average norms and was found to contain up to 32% of borneol in form of borneol acetate. 2 Besides borneol this oil contained santene, *l* alpha pinene, *l* beta pinene, camphene, *l* alpha phellandrene and dipentene. All these compounds are found in amounts harmonizing with the corresponding fractions. 3 In the third fraction of the carbohydrate portion of the oil of *Abies sibirica* there is apparently found an unknown carbohydrate. This carbohydrate was nitrated and this nitrated product was found to possess different properties than the nitrated products of the other carbohydrates of this oil.—V V WILLIAMS and A S ONISCHENKO *Sovetsk Pharm* 2 (1935) 15 (A S)

Aromatics—Noteworthy New Special. A review.—B REGRUB *Riesstoff Ind Kosmetik* 10 (1935), 79-83 (H M B)

Estragon and Hyssop—A Survey of Production and Characteristics of. A review of the cultivation, distillation and chemistry of the oils. The constants for oil of estragon (*Artemisia dracuncululus* L.) were found to be spec grav at 15° 0.926-0.966, optical rotation +3°20' to +4°12', refractive index at 20° 1.5112-1.5201, saponification value 2.8-17.7. The constants for oil of hyssop (*Hyssopus officinalis* L.) were found to be spec grav at 15° 0.940-0.956, optical rotation -16°18' to -18°20', saponification value 4.7-12.1, refractive index at 20° 1.4800-1.4829, ketone content (*l* pinocamphone) was about 45%.—ERNEST S GUENTHER *Am Per fumer* 30 (1935) 238-240 (G W F)

Gamboge—Contribution to the Chemistry of. The author investigated the gum resins from various trees of the Family *Garcinia*, especially *Garcinia Hanburyi* attempting to isolate the active constituents. The material was extracted with ether, the resinous portion being obtained as a slimy residue. Attempts at separation with various solvents gave no crystalline products. Separation with dilute soda solutions and alkalis gave three fractions. In soda 84% of the pure resin (mostly acids) went into combination. Alkali took up 12% of apparently phenolic compounds. The balance consisted of an ester which was separated into an alkali soluble and an alkali insoluble portion upon saponification. All resin constituents are yellow in color, the acid constituents dissolve in alkali with a yellow color, the phenolic constituents with a red color. The soda soluble portion when treated with acetic acid and sodium acetate gives prisms or triangular plates (yellow) of acetyl α cambogic acid which liquefy at 163° and are completely melted at 190°. The acid has the formula $C_{31}H_{36}O_7$ and appears to be unsaturated. After splitting off the

acetyl group the α cambogic acid shows the formula $C_{28}H_{32}O_7$ $\begin{matrix} \text{COOH} \\ | \\ \text{C}_3\text{H}_5\text{O}_3 \\ | \\ \text{OH} \end{matrix}$ This can also be identified in the resin.

In the alkali soluble portion the investigation for esters was fruitless and in the third fraction only one ester was found of which the products of hydrolysis could not be identified. The laxative properties of acetyl α cambogic acid determined with mice and compared with that of the total resin as well as that of the gum resin showed the latter to have the strongest action. The gum portion evidently increasing the laxative properties of the resin.—MARTHA FURRER (Dissertation, Basel) *Pharm Ztg* 79 (1934), 1082 through *Pharm Weekblad* 72 (1935) 828 (E H W)

Leaf Oils of the Washington Conifers VII *Juniperus Occidentalis*. This tree grows in

northwestern United States, seldom at elevations of less than 6,000 feet. Steam distillation of leaves and branches yielded 0.36% of oil. Aldehydes, ketones and primary alcohols were absent or nearly so. Composition was found to be about as follows: bornyl acetate, 40, borneol, 11, alpha phellandrene, cymene and probably camphene, 35, acetic acid 0.2, phenols, 0.5, compounds of higher boiling point and loss, 14.—E. V. LANN and LOUIS FISCHER *J. Am. Pharm. Assoc.*, 14 (1935), 613 (Z. M. C.)

Oil of Citronella The following comparative figures are given for the production of oil of citronella

Year	Netherlands Indies (Mostly from Java)	Ceylon
1929	879 tons	532 tons
1930	818 tons	546 tons
1931	893 tons	542 tons
1932	996 tons	576 tons
1933	1529 tons	657 tons
1934	1783 tons	692 tons

The author calls attention to the differences between East Indian and Ceylon citronella oil. Java oil has a lower specific gravity and a higher citronellal and total geraniol content than the Ceylon oil. A great deal of the Ceylon oil is adulterated. The author recommends that oil of citronella be included in the Netherlands Phar.—P. A. ROWAAN *Pharm. Weekblad*, 72 (1935), 853 (E. H. W.)

Oil of Myrtle—Survey of A review of the botany, cultivation, constants and chemistry of oil of myrtle (*Myrtus communis* L.)—ERNEST S. GUENTHER *Am. Perfumer*, 30 (1935), 287-288 (G. W. F.)

Photochemical Notes No. 113 **An Unusual Peppermint Oil** Report is made of a sample of peppermint oil distilled in 1930. In a little more than a year it had acquired a distinct orange tint, was cloudy and had a resinous sediment. Physical and chemical constants were determined for crude oil, rectified oil and first cohobate. Because density (0.962, 0.9145 and 0.9179) varied from official oil (0.896 to 0.908) the opinion of others was sought. The A. M. Todd Company asked for a sample and reported findings. These are tabulated with U. S. P. requirements for easy comparison. Comments are quoted. Fritzsche Brothers submitted two opinions and both are quoted. A sample of the rectified oil was saponified and the saponified oil distilled with steam and collected in fractions. Redistillation showed that three larger fractions had densities greater than U. S. P. limit. Fraction 200° to 220° placed in a freezing mixture yielded menthol and acetylation revealed 97.8% alcohol computed as menthol. There was no thymol or carvacrol or pulegone. The only thing that can be done with such an oil under present U. S. P. standard is to blend it with other oils that are relatively light.—SISTER M. FRANCIS XAVIER *J. Am. Pharm. Assoc.*, 24 (1935), 543 (Z. M. C.)

Salvia Sclarea—Accumulation of Ethereal Oil in, of Central Asia *Salvia Sclarea* belonging to the family of Labiatae is a plant which lives a few years and which is found in a wild state. Because of its ethereal oil content it is at present cultivated in France, Italy and to some extent in Germany, Russia and other countries. The ethereal oil consists of linalol combined in form of acetic and formic ethers, of free linalol and of slight amounts of a free acid and a substance having a carbonyl group. It has been found that the chemical make up of this ethereal oil is dependent on climatic conditions, on the stage of development of the plant, on the method of collection of the plant, and on the method of its dry distillation. The author attempted to determine the relation of the chemical make up of the ethereal oil to the stage of development of the plant, its age and type, under conditions found in Central Asia. Experiments were carried out in Samarkand where the plants of 1, 2 and 3 years of age were studied. The plants were grown from seeds collected of wild plants, and represented a mixture of about 7 types. The results obtained have shown that the main mass of the ethereal oils accumulates in the flowers and the region neighboring immediately upon them, and only a negligible amount of these oils is found in the remaining parts of the plant. The total amount of the ethereal oil is dependent on the state of development, type and age of the plants. The maximum amount of ethereal oil was found in plants two years of age at the end of blooming, while the minimal amount is found in plants three years of age during the first period of their development.—T. K. GAPONENKOV *Soviets Pharm.*, 4 (1935), 31 (A. S.)

Stone Fruit Flavors Stone fruits (genus *Prunus*) are subjected to hydraulic pressure in the cold, concentrated *in vacuo* and preserved with sugar or alcohol. The extracts may be fortified with synthetics. For peach essence, the following may be used: gamma-undecalactone, acetaldehyde, ethyl acetate, butyrate and valerate, iso amyl acetate and butyrate, vanillin, anisaldehyde, sweet orange oil, cardamom oil, neroli oil and benzaldehyde or bitter almond oil. S. A. P. The latter may be obtained from the kernels by maceration and steam distillation. Synthetics used for peach are also applicable to other stone fruits with the exception of γ -undecalactone. Ethyl butyrate and isoamyl butyrate are suggestive of apricots, ethyl acetate and benzoate as well as isoamyl formate and ethyl cinnamate are used in cherry essences. The latter two and a trace of oil of clove are used for plum.—H. STANLEY REDGROVE. *Am Perfumer*, 30 (1935), 285-310.

(G. W. F.)

Terpenes—Recent Progress in the Chemistry of A review with references.—J. L. SIRON. *J. Chem. Soc.* (1935), 781-785.

(G. W. F.)

Trachyspermum Copticum Linc—Accumulation of Thymol in 1. The amount of etheral oil which may be obtained from *Trachyspermum copticum* Linc. is dependent on the stage of development of the latter: the maximum amount is obtained in the most mature and the minimum in the least mature plants. 2. The etheral oil accumulates chiefly in the upper portions of the plant, if the latter is represented by 100% the amount found in the middle portion of the plant is equal to 30.6% and that in the lower portion of the plant to 10.5%. 3. The etheral oils obtained in this manner contain among the phenols chiefly thymol and a limited amount of carvacrol. 4. The phenol content and consequently the thymol content in the etheral oil depends on the state of development of the plant. 5. The thymol can be obtained not only from the oil expressed from the seeds, but also from the juice expressed from the entire plant.—T. K. GAPONENKOV. *Soviets Pharm.*, 3 (1935), 17.

(A. S.)

Violet Odor—Natural A continuation of the work which appeared in *Perfumery Essential Oil Record*, 26 (1935) 100 is given. Violet leaf oil, ionone and irone are discussed.—F. K. DONOVAN. *Perfumery Essential Oil Record*, 26 (1935) 303.

(A. C. DeD.)

Fixed Oils, Fats and Waxes

Carqueja (*Baccharis Genistelloides* Pers.)—Contribution to the Study of a Medicinal Plant of Widespread Use in Argentina. The resin of carqueja has an acid value of 116, saponification value of 182, ester value of 66 and an iodine number (Hubl) of 74.93. The Phar. of Brazil uses carqueja alone and in combination with other plants for its stimulation of the biliary function and the activity of the liver.—C. CROCCO and H. BASSO DASTUGUE. *Ann. Farm. Biogum.* 5 (1934) 51-60, through *Chimie et Industrie*, 33 (1935) 918.

(W. A. P.)

Castor Oil—Refining A brief review of work carried out during the past few years on the refining of pharmaceutical and lubricating castor oil and more particularly of the author's process in which the pressed oil is treated with caustic soda without prefiltration, the presence of the albuminous matter favoring the separation of a coarse grained soap stock which readily settles out.—R. HEUBLUM. *Mat. grasses*, 27 (1935) 10 463, 10 482-10 483.

(A. P. C.)

Cod Liver Oil—Medicinal, Obtained by Steam Methods Vitamin Content. After a review of the work of Poulsson and of Schrader (*Pharm. Ztg.*, 49 (1934) Nos 53 and 54) S. concludes: (1) for internal use the oil obtained by steam methods is the best since it has been shown that vitamins absorbed by the liver tissues are freed by the heat without destroying their action, (2) that a vapor of steam is necessary to remove the bad smelling free acids and (3) that oxygen in the air and not the temperatures is destructive to vitamin A. It appears likely on these grounds that there may be a loss of vitamin A when the oil is used in salves or emulsions.—E. SCHWEISZINGER. *Apoth.-Ztg.*, 50 (1935), 779-780.

(H. M. B.)

Coula Edulis—Seed Oil of The physical and chemical constants and the composition of coula oil (from *Coula edulis* Baillon) are given and compared with those of olive and tsabal oils. Coula oil contains 87.1% of oleic acid and is a good source for the preparation thereof.—A. STEGER and J. VAN LOON. *Rec. trav. chim.*, 54 (1935), 502, through *Squibb Abstr. Bull.*, 8 (1935), A 971.

Gossypol—Effect of, on Color of Cottonseed Oil Cotton seeds contain an oil soluble poisonous dye, gossypol (I). The effect of I on the color of cottonseed oil (II) was studied. As the concentration of I in II was quadrupled the color intensity was doubled. Heating the solu-

tions intensified the color to a maximum at 90–120° after which it decreased to a minimum at 120–150° and thereafter again increased. The amount of unchanged precipitable I decreased with increasing temperature. The color and I content of heated solutions decreased on standing, the decrease being greater for the solutions heated to lower temperatures and containing a greater initial amount of unchanged I. The changes in the color of the solutions was shown to be due mainly to the heating and only little if at all to oxidation. It appears therefore, that the color of II is largely dependent on the I content, although the other factors may play a part.—M. PODOLSKAJA *Fellchem Umschau*, 42 (1935), 96, through *Squibb Abstr Bull*, 8 (1935), A 929.

Halibut Liver Oils—Characters of. The natural variations of halibut liver oils, particularly in vitamin content, are very great. These variations are partly seasonal and partly depend on the region in which the fish is caught. Therefore, it is the practice to standardize the oils for sale to a definite vitamin A content. This may be done either by mixing strong and weak halibut liver oils to give the desired vitamin content or by diluting a strong halibut liver oil with a fish liver oil such as cod liver oil, or even with a vegetable oil. It is important in laying down standards for the natural oil to be sure that the material tested is genuine halibut liver oil and nothing else, since, if any other oil is added the product cannot be described as natural halibut liver oil. When testing halibut liver oil, it is recommended that the Rosenmund-Kuhnemann pyridine dibromide method be used since this method gives more consistent results when a high proportion of cholesterol is present.—N. EVERS and W. SMITH *Pharm J*, 134 (1935) 417 (W B B).

Pannarium Laurinum—The Highly Unsaturated Acid of the Kernels of. The kernels yield 44% of a butter-like solid having a high refractive index and iodine value. An acid, crystallizing in large plates (m p 83.4°), was obtained by crystallization from petroleum ether. It becomes transformed by atmospheric oxygen (less in refrigerator) to an amorphous material. It was found to absorb 4 molecular proportions of hydrogen and upon potassium permanganate oxidation it yielded somewhat less than one molecular proportion each of azelaic and propionic acids and a quantity of oxalic acid. The formula $\text{CH}_3\text{CH}_2(\text{CH}=\text{CH})_4(\text{CH}_2)_2\text{CO}_2\text{H}$ is assigned. It is thought to be the first conjugated acid of the tetracene series to be reported from a vegetable or animal source.—E. H. FARMER and E. SUNDERLAND *J Chem Soc* (1935) 759–761 (G W F).

Pannarium Macrophyllum—The Highly Unsaturated Acid of the Kernels of. The oil constitutes 70% of the kernels, or 4% of the nuts. A highly unsaturated acid (m p 45.5–46.5°) was obtained by fractional crystallization from petroleum ether. Its identity with alpha elaeostearic acid was confirmed. W. B. BROWN and E. H. FARMER *J Chem Soc* (1935), 761–763 (G W F).

Sapucainha Oil—Constituents of. Sapucainha oil was obtained from the seeds of the Brazilian plant *Carpotroche Brasiliensis* Endl. (*Flacourtiaceae*) and showed as constants d_{20}^{20} 0.9503, m p 22°, f p 13–15°, $[\alpha]_D^{20} +54.2^\circ$ ($c = 5$, in chloroform), acid no 17, sap no 195, iodine no 101. Saponification yielded a small quantity of phytosterol m p 121°, and crude fatty acids with constants m p 43°, $[\alpha]_D^{20} +56.4^\circ$, ($c = 0.4136$ in chloroform), acid no 214, iodine 109. Chaulmoogric acid was obtained by repeated recrystallization from 70% alcohol, m p 68°, $[\alpha]_D^{20} +62.9^\circ$, acid no 199.4, iodine no 92.9, amide m p 102° $[\alpha]_D^{15} = +61.9^\circ$, ($c = 5$ in chloroform). Hydnocarpic acid was obtained from the mother solutions of the first acid by precipitation from 90% alcohol with alcoholic lead acetate and was recovered from the lead precipitate (?). It had as constants m p 58°, $[\alpha]_D^{20} +64.5^\circ$, acid no 211.4, iodine no 97.1, amide m p 105–106°, $[\alpha]_D^{15} +61.4^\circ$.—T. KARIYONE and Y. HASEGAWA *J Pharm Soc of Japan*, 54 (1934), 28–29 (R E K).

Sarcostigma Kleinu—Oil of. The bark, fruit and seed oil of *Sarcostigma kleinu* have been used in the treatment of rheumatics, leprosy, scabies, abscesses and hemorrhoids. Prolonged use however, affects the eyes and overstimulates the nervous system. In spite of the therapeutic use of the plant the chemistry of the oil has not been studied. The following constants were determined for the seed oil: solidification point 20°, $d_4^{29.5}$ 0.9274, viscosity (Engler viscosimeter) E_{20} 7.14, $[\alpha]_D^{27}$ 1.0606, n_D^{40} 1.4649–1.4651 depending on the refractometer, acid number 11.89 which is rather high and may be due to the fact that the seeds were kept for several months before extraction. Saponification number 196.6. Reichert-Meissl number 0.55, Polenske number 0.19. Acetyl number 0. Hehner number 93.8–94.6, depending on the method, thiocyanate number 49.48, iodine number 69.16–72.63, depending on the method, and hexabromide number 0. The oil contained a small amount of unsaponifiable matter which gave a sterol reaction, the crystalline

Stone Fruit Flavors Stone fruits (genus *Prunus*) are subjected to hydraulic pressure in the cold, concentrated *in vacuo* and preserved with sugar or alcohol. The extracts may be fortified with synthetics. For peach essence, the following may be used: gamma undecalactone, acetaldehyde, ethyl acetate, butyrate and valerate, iso amyl acetate and butyrate, vanillin, anisaldehyde, sweet orange oil, cardamom oil, neroli oil and benzaldehyde or bitter almond oil. S. A. P. The latter may be obtained from the kernels by maceration and steam distillation. Synthetics used for peach are also applicable to other stone fruits with the exception of γ -undecalactone. Ethyl butyrate and isoamyl butyrate are suggestive of apricots, ethyl acetate and benzoate as well as iso amyl formate and ethyl cœnanthate are used in cherry essences. The latter two and a trace of oil of clove are used for plum.—H. STANLEY REDGROVE *Am Perfumer*, 30 (1935), 285, 310.

Sapucainha Oil—Constituents of Sapucainha oil was obtained from the seeds of the Brazilian plant *Carpotroche Brasiliensis* Endl. (*Flacourtiaceae*) and showed as constants d_{20}^{20} 0.9503, m. p. 22°, f. p. 13–15°, $[\alpha]_D^{20} +54.2^\circ$ ($c = 5$, in chloroform), acid no. 17, sap. no. 195, iodine no. 101. Saponification yielded a small quantity of phytosterol, m. p. 121°, and crude fatty acids with constants m. p. 43°, $[\alpha]_D^{20} +56.4^\circ$ ($c = 0.4136$, in chloroform), acid no. 214, iodine 109. Chaulmoogric acid was obtained by repeated recrystallization from 70% alcohol, m. p. 68°, $[\alpha]_D^{20} +62.9^\circ$, acid no. 199.4, iodine no. 92.9, amide, m. p. 102°, $[\alpha]_D^{15} +61.9^\circ$ ($c = 5$ in chloroform). Hydnoicarpic acid was obtained from the mother solutions of the first acid by precipitation from 90% alcohol with alcoholic lead acetate and was recovered from the lead precipitate (?). It had as constants m. p. 58°, $[\alpha]_D^{20} +64.5^\circ$, acid no. 211.4, iodine no. 97.1, amide m. p. 105–106°, $[\alpha]_D^{15} +61.4^\circ$.—T. KARIYONE and Y. HASEGAWA *J. Pharm. Soc. of Japan*, 54 (1934) 28–29 (R. E. K.).

Sarcostigma Kleinii—Oil of The bark, fruit and seed oil of *Sarcostigma kleinii* have been used in the treatment of rheumatism, leprosy, scabies, abscesses and hemorrhoids. Prolonged use however affects the eyes and overstimulates the nervous system. In spite of the therapeutic use of the plant the chemistry of the oil has not been studied. The following constants were determined for the seed oil: solidification point 20°, $d_4^{29.5}$ 0.9274, viscosity (Engler viscosimeter) E₃₀ 7.14, $[\alpha]_D^{27}$ 1.0606, n_D^{40} 1.4649–1.4651 depending on the refractometer, acid number 11.89, which is rather high and may be due to the fact that the seeds were kept for several months before extraction, saponification number 196.6, Reichert-Meissl number 0.55, Polenske number 0.19, acetyl number 0, Hehner number 93.8–94.6, depending on the method, thiocyanate number 49.48, iodine number 69.16–72.63 depending on the method, and hexabromide number 0. The oil contained a small amount of unsaponifiable matter which gave a sterol reaction, the crystalline

form resembled phytosterol, the acetate melting at 132–134° —P S VARMA, N N GODBOLE and A GANGADHARAN *Fettchem Umschau*, 42 (1935), 88, through *Squibb Abstr Bull* 8 (1935) A 939

Glycosides Ferments and Carbohydrates

Adonis Vernalis—Method of Extracting Active Principles of The use of 0.5–1.0% of acetone in water instead of pure water in the usual (Hoffman-LaRoche) extraction of the active glucosides gives a larger yield —G TONI and P FARINI *Arch farmacol sper* 49 (1935), 186, through *Chem Abstr* 29 (1935), 4517

Æsculus Turginata, Blume—Saponin of the Seed of The author endeavored to apply Winterstein's method of preparing the saponin æscinin from *Æsculus hippocastanum* to the Japanese species *Æsculus turginata*. A saponin was isolated from the seeds of the latter species but only after some modification in the procedure. The resultant compound was not identical with Winterstein's saponin and was named *Japoæscinin* $C_{65}H_{101}O_{35}$, m p about 200° freely soluble in water, producing foam positive Liebermann reaction. Mineral acid readily hydrolyzed it to the pro saponin $C_{59}H_{81}O_{26}$ m p 210° dibromide prepared in methanol dec 175°. Further hydrolysis in alcoholic solution with mineral acid yielded Japoæscigenin $C_{35}H_{55}O_7$ m p 258°, probably isomeric with Winterstein's æscigenin m p 309°, 4 active hydrogens by Zerewitinoff's method. The prosapogenin is very difficultly hydrolyzed and much of it is recovered unchanged even after 50 hours refluxing with 5 to 10% hydrochloric or sulphuric acid. However the genin is readily saponified yielding tiglic acid and *Japoæscigenol* $C_{30}H_{49}O_6$ m p 307°, alcoholic solution neutral 5 active hydrogens by Zerewitinoff's method indicating 5 hydroxyl groups the remaining oxygen atom probably constituting a bridge, positive Liebermann reaction, one double bond. Two atoms of bromine react but the product separated is a monobromide $C_{30}H_{47}O_6Br$ m p 196°. Acetylation gives a tetra acetate m p 198°. Apparently a tertiary hydroxyl group was eliminated as a molecule of water —T MATSUKAWA *J Pharm Soc Japan* 55 (1935) 82–84

(R E K)

Cardiotonic Drugs—Investigation of Unreported sources were sought among folk medicines for cardioactive principles like the digitalis glucosides. Variations in the potency of commercial adonis are not attributable to the temperature at which the drug is dried. Assuming a value of 100% to represent the activity of the over ground portions of this herb, the activity was found to be distributed between the plant parts as follows buds, 53%, whole blossoms 48%, petals, 26%, roots, 26%. Alcoholic extracts were made in a Soxhlet apparatus of the herb and roots, respectively, of *Adonis vernalis* L, *A autumnalis* L, *A æstivalis* L, *A wolgensis* Stev, *A pyrenaica* DC, *Knowltonia vesicatoria*, *Eranthis hiemalis* Sal. The relative potencies of these extracts were determined by the 24 hour method of Straub. On the basis of color reactions the active constituents of all the species of adonis investigated are chemically similar, but by the same sign are unlike the constituents of *Eranthis hiemalis*. By appropriate treatment, the latter drug was resolved into a fatty acid, a resin acid, an active water and chloroform soluble fraction (Eranthin A) and an active water- and alcohol soluble but chloroform insoluble fraction (Eranthin B). Both active fractions represented the glucoside in an impure state. The two glucosides are not members of the adonis group since both of them gave reactions of the digitalis type. The results of different extraction methods applied to *Gratiola officinalis* L indicate that the cardiac activity is less readily extractable from *G officinalis* than from *Digitalis purpurea*. The susceptibility of the frog to both *G officinalis* and *D purpurea* is similar using spring or autumnal frogs but no parallel could be drawn between the cumulative actions of the two drugs. Contrary to Montpellier, gratiolin (m p 268–269° C) possesses no cardiac activity. Gratioligenin and gratiogenin are likewise without activity. A cardioactive glucoside was isolated from *G officinalis* which the author designated gratiotoxin. In crude form it was soluble in alcohol, glacial acetic acid, pyridine and chloroform but soluble in water with difficulty. Potencies of alcoholic Soxhlet extracts were determined for *Bowiea volubilis* Harv, *Ornithogalum longibracteatum*, *Ornithogalum umbellatum* L, *Paris quadrifolia* L, *Polygonatum verticillatum* (L) All, *Sansevieria kirkii* (Bak) *Semele androgyna* (L) Kth, *Velltheimia viridifolia* (L) Jacq, *Velltheimia viridifolia* (L) Jacq. In frogs *Paris quadrifolia* elicits no toxic symptoms of any form. In the last group of drugs *Bowiea volubilis* (bulb) was sufficiently active to warrant chemical study. The result of the chemical study was the isolation of two highly active glucosides of the scillaren type. The isolation pro

cedure and color reactions of both glucosides are given —R JARETZKY *Arch Pharm* 273 (1935), 334 (L L M)

Digitalis Purpurea—Digitoxin Content of *D. purpurea* from Canavese contains 0.22% of digitoxin —C BERTONASCO *Boll chim farm*, 74 (1935), 114, through *Chem Abstr*, 29 (1935), 4516

Digitalis Purpurea and Lanata A discussion concerning chemistry and relation between the different glucosides of both species —ARTURO STOLL *Farm Moderna*, 46 (1935), 287 (A E M)

Honeysuckle—Investigation of Some Species of The article consists of several tables of experimental data on *Lonicera Xylosteum* L and *L. alpigena* L, which are reviewed in detail and conclusions stated. The first table shows the results of studies on the fruits of the above species, the second compares the fruits of the above with those of *L. nigra* and the third gives data on the reducing sugar present. The berries of *L. Xylosteum* and *L. alpigena* contain an abundance of reducing sugar, a small amount of glucosides hydrolyzed by invertin and some products hydrolyzable by emulsin. The reducing sugar in the berries contains glucose, identified by the author as the *p* methyl glucoside. In *L. Xylosteum* this glucose represents 43% of the reducing sugar and in *L. alpigena* it represents 36% —C BEGUIN *Pharm Acta Helv*, 10 (1935), 109 (M F W D)

Labiatae—Tannins in The author found 10% and over of tannins in *Thymus vulgaris* L, *Mentha piperita* L, *Lavandula officinalis*, Charv., and others. 5% and over in *Marrubium vulgare*, L, *Rosmarinus officinalis* L, *Salvia officinalis*, L, *Hyssopus officinalis*, L, *Origanum vulgare*, L, *Origanum majorana*, L, *Thymus serpyllum* L, *Orthosiphon stamineus*, Benth and others, and less than 5% in *Melissa officinalis*, L —*Scientia Pharm*, 10 (1935), 23, through *Pharm Tijdschr Nederland-Indië* 13 (1935), 54 (E H W)

Microsechium Helleni, Tand (Pseudosechium Rand)—Constituent of This member of the Cucurbita family is used in Mexico as a means of catching fish by throwing discs of the root in the water and in a short time the fish come to the surface stunned and may then be caught. The drug has a bitter taste and produces a dust which causes sneezing and tears, in water a froth is produced which indicates a saponin body. From the drug 0.75% glycoside is produced as a white body with a bitter taste easily soluble in water and alcohol, insoluble in ether, chloroform and petroleum ether. It is prepared by the precipitation of the alcohol extract with tannin, decomposing the tannate with lead oxide and precipitation of the alcohol solution of the crude glycoside with ether, by repeated solutions and precipitations with alcohol and ether, respectively, the pure compound is formed or the drug is boiled with alcohol and precipitated from the cold alcohol solution by addition of ether. Examination of the glycoside indicates that it possesses a saponin like action, dissolves red corpuscles, acts as a strong protoplasmic poison, produces intense local irritation, acts on the eyes, produces suppuration of the undercellular tissues and abscesses and increases the permeability of the blood vessels —G HEYL and O VOLLAND *Apoth-Ztg* 50 (1935) 310-312 (H M B)

Persica Vulgaris (Peach Tree) and Persicoside—Study of The authors have isolated a heteroside ("persicoside") from the 5 year old bark of *Persica vulgaris*. This heteroside differs from that obtained by the Japanese workers, since on hydrolysis C and R obtained glucose and hesperetol. **Extraction of Glycoside** —Boil the dried powdered bark with 90% alcohol. Distill off the alcohol until a syrupy residue remains. Dissolve in warm water, shake out with ether and set the remaining aqueous layer in a cool place. Brown crystals appear, and these may be purified from boiling water. The crystals are colorless, odorless, shiny and needle-like. They are soluble in strong alcohol and the melting point is 258-260°. From the elemental analysis the formula $C_{27}H_{34}O_{11}$ is proposed —C CHARAUX and J RABATE *J pharm chim*, 21 (1935), 495 (M M Z)

Sophoricoside New Heteroside from Fruits of *Sophora Japonica* The heteroside was extracted from the dried fruits with boiling alcohol. The alcohol was distilled off until a syrupy residue remained, and this was extracted with ether. The aqueous portion was allowed to stand until the solid separated. The solid was removed and recrystallized from ether. The glycoside crystallized in white prisms, which are slightly soluble in water and insoluble in organic solvents. It is odorless and gives a yellow color with sodium hydroxide. On hydrolysis with acids there is obtained glucose and a phenolic compound which the workers named sophoricol but it was later

shown to be identical with genisteol, isolated by Perkin and Newbury from *Genista tinctoria*—C CHARAUX and J RABATÉ *J pharm chim*, 21 (1935), 546 (M M Z)

Sugars—Crystalline Structure of Part I Preliminary data on sugars and glycosides is reported The cell dimensions for beta-methylarabinoside, alpha methylfucoside and alpha methylgalactoside 6 bromhydrin are reported (in Å)

	Arabinoside	Fucoside	Bromhydrin
d_{100}	8 10	9 96	10 58
b	7 74	7 87	7 81
c	5 89	5 72	2 X 5 62

E G COX T H GOODWIN and A I WAGSTAFF *J Chem Soc* (1935), 978-984 (G W F)

Verbenal Officialis L—Constituents of Verbenalin, a crystalline glucoside from *Verbena officinalis* L, and cornin, a glucoside from the root cortex of *Cornus florida* L are identical Both glucosides have been assigned the same molecular formula, $C_{17}H_{24}O_{10}$, by different investigators both possess strong reducing properties, both are split by the enzyme emulsin, and upon hydrolysis yield d glucose For cornin the melting point and specific rotation are respectively $182-183^{\circ}$ C and $[\alpha]_D^{25} = -180.6^{\circ}$, for verbenalin they are 181.56° C and $[\alpha]_D^{25} = -180.52^{\circ}$ There was no depression of the melting point by mixed melting point determination—B REICHERT *Arch Pharm*, 273 (1935), 357 (L L M)

Other Plant Principles

Ch'ai Hu (*Bupleurum Falcatum* L)—Constituents of Roots of This ancient drug is used as antipyretic and expectorant From 13.6 Kg of dried material is obtained 3.5 Gm of an essential oil, b_p $130-157^{\circ}$ d_4^{20} 0.9194 From the portion which is non volatile and insoluble in water are obtained a new alcohol bupleurumol, melting at $163-164^{\circ}$, and oleic linoleic, palmitic stearic and lignoceric acids—YOUNG FONG CHI and CHI MING MA *J Chinese Chem Soc*, 3 (1935), 78, through *Chem Abstr* 29 (1935) 4515

Coriaria Japonica, A Gray (IV)—Poisonous Constituents of It was shown previously that coriamyrtin was not a glucoside although hydrolysis with acids produced a substance which reduced Fehling's solution The dihydro derivative (colorless needles, m p 255.5° , $[\alpha]_D^{20} +25.2^{\circ}$ in chloroform, negative Riban reaction) of coriamyrtin obtained by catalytic hydrogenation, is converted by boiling dilute sulphuric acid into an isomer which forms a crystalline tolylosazone m p $202-203^{\circ}$ This indicates either an α -hydroxy-ketone or -aldehyde group in the molecule Like picrotoxinin coriamyrtin and dihydrocoriamyrtin form acetone when treated with alkali Chlorine substitutes one atom of hydrogen to form the mono derivative m p $204-205^{\circ}$, white prisms—T KARIYONE and K KASHIWAGI *J Pharm Soc Japan* 54 (1934), 31-32 (R E K)

Daphne Genkwa—Constituents of The Chinese drug Yuen hua, *Daphne genkwa*, Sieb et Zucc has been in medical use since 160 B C, it is also called Chojisakura or Fujumodoki in Japan Nakao has already recorded the presence of a vesicating substance in the drug Further investigation shows that it contains the following constituents sitosterol $C_{27}H_{48}O$ m p $136-137^{\circ}$ C, apigenin, $C_{15}H_{10}O_6$ m p 352° C, genkwamin, a new flavone $C_{16}H_{12}O_6$ m p 206° C and benzoic acid Genkwamin is found to contain one methoxyl group, and its molecular structure is further discussed—M NAKAO and K F TSENG *J Shanghai Sci Inst* 1 (1933), 1, through *Quart J Pharm Pharmacol*, 8 (1935), 265 (S W G)

Hydrangea Paniculata—On the Constituents of, and on Hydrangin *Hydrangea paniculata* grows wild in the hilly regions of Japan and is used as a glue in the manufacture of paper The authors extracted the flowers and flower stalks with benzene and obtained an alcohol soluble, crystalline product from the extract This product proved to be umbelliferone $C_9H_6O_3$, m p 224° , bluish fluorescence in the aqueous solution, sublimed without decomposition mono methyl ether by diazomethane m p 114° , identical with synthetic umbelliferone and its derivatives Bondurant and later Schroeter isolated a substance called Hydrangin from *Hydrangea arborescens* a native of the United States In view of the close botanical relationship between the two species the authors believe that Hydrangin is identical with umbelliferone—A ASHIMOTO and T KAWANA *J Pharm Soc Japan* 55 (1935) 44 (R E K)

Phytochemical Notes No 108 A Phytochemical Study of the Seed of the Digger Pine

Samples of ground seed, of seed coats and of endosperm were extracted with selective solvents. Data are tabulated. Then a petroleum ether extract consisting chiefly of fatty oil was prepared and cold alcoholic percolate was concentrated. From saponification, iodine and thiocyanogen values, percentages were calculated: 4.3% saturated fatty acids, 50.5% oleic acid and 45.2% linoleic acid. Further study of the oil after fractionation indicated heptanoic acid, nonanoic acid and azelaic acid, and fatty acids of 16 and 18 carbon atoms. These data indicate that the first double bond is at the 9-10 position; also that this or a second double bond is in the 6-7 or 9-10 position from the end. Had malonic acid been isolated this would indicate only oleic and linoleic acids. Malonic acid formed must have been lost during purification. Study of the soap solution indicated saturated fatty acids 5.5%, oleic acid 51%, linoleic acid 43.5%. Lead soap of the liquid fatty acids and of the solid fatty acids were prepared and studied. Methyl esters of the supposedly saturated acids were distilled and constants determined. Presence of palmitic acid was indicated in a mixture of two esters and two others yielded stearic acid. Further study of liquid fatty acids seemed to indicate dihydroxy stearic acid. Experiments to see if there were volatile fatty acids gave negative results.—JOSEPH SEMB *J Am Pharm Assoc*, 24 (1935) 609 (Z M C)

Plants, Toxic—Chemical Problems Connected with the Study of Investigation and Isolation of the Active Principles I Alkaloids These may be extracted easily by exhaustion with a mixture of equal parts of alcohol, ether and ammonia in the case where the base is free and soluble in organic solvents. In other cases, the alkaloids may be first set free by using a weak acid. The solvent is evaporated and the residue dissolved in a weak acid. They may be purified by the process of alternately rendering soluble the free base in an organic solvent and the salts in an aqueous solvent. The separation of the various alkaloids may be accomplished by their different degrees of basicity. Crystallization and sublimation under low pressure may be of great aid. **II Glucosides** The biochemical method of Bourquelot is employed. Extract with boiling alcohol (96°) evaporate and dissolve the residue in water. Keep half of the solution for comparison and add yeast to the other half. After complete inversion destroy the yeast with heat, cool and add emulsin. A variation in the rotatory power in the dextrorotatory direction indicates the presence of glucoside. The method of separation varies with the case. For example, the aqueous solution may be purified with lead acetate. The greater part of the glucosides remain in solution. Entirely eliminate the lead, and, after filtering, concentrate to a syrupy consistence and dissolve in alcohol. Complete the purification by successive crystallizations from a warm solution of ethyl acetate. One may also add a sufficient quantity of calcium sulphate and calcium carbonate to the purified solution to obtain a dry powder which may be extracted directly with ethyl acetate. Finally, certain plants were extracted directly with ethyl acetate without other previous operation. **III The bitter principles** may be extracted with chloroform after treatment of the plant with petroleum ether to eliminate fat.—C RIMINGTON *J South African Chem Inst*, 17 (1934), 44-47 through *Chimie et Industrie* 33 (1935), 918-919 (W A P)

Uvaria Catocarpa—Constituents of The fruits of *Uvaria catocarpa* (Diels) (Fam. *Annonaceae*) are used in the local medicine of Madagascar under the name of Senasena or Senanasena finding use as stomachics, febrifuges, sedatives, tonics and disinfectants. Analysis of the fruits showed **A Seeds**—(1) Fats Saponifiable 13.96%, unsaponifiable 0.2445%, containing 0.075% phytosterol, total glycerides 19.30%. Empirical formula of the separated crystallized fatty acid $C_{18}H_{32}O_7$. (2) Carbohydrates reducing sugars (glucose) 1.05%, hydrolyzable sugar (as cane sugar) 0.4089%, starch 16%. (3) Organic acids (a) Non-volatile oxalic, citric, malic, (b) volatile acetic and formic. (4) Resin Semi liquid, dark brown and bitter, 4.40%. (5) Proteins albumins, globulins and alkali albumins. Total nitrogen 1.89% (corresponding to 11.80% protein). **B Pericarp**—(1) Fats Saponifiable 1.92%, unsaponifiable 0.422% containing 0.0774% phytosterol, total glycerides 3.04%. (2) Carbohydrates reducing sugars (glucose) 1.35%, hydrolyzable sugars (sucrose) 0.1425%. (3) Organic acids (a) Non volatile oxalic, citric and malic, (b) volatile acetic, formic and butyric. (4) Resin solid, brownish black, acid taste 5.63%. (5) Proteins albumins, globulins and alkali albumins. Total nitrogen 1.545% (corresponding to 9.65% proteins). (6) Volatile oil Yellowish green fragrant odor D 0.9244, refr ind 1.5231 at 18°. (7) Glucosides A glucoside was found which was hydrolyzable by emulsin. This ferment is present in the pericarp. **C Entire Fruit**—Inorganic constituents. Ash 1.56% containing Cu, Fe, Mn, K, Na, P, S and As.—J M COISNARD Dissertation (Paris), through *Pharm. Tijdschr. Nederland-Indie*, 13 (1935) 51 (E H W)

Unclassified

Coumarins—Improved Method for the Synthesis of, by v Pechmann's Method A solution of the phenol and beta-keto ester in absolute alcohol is saturated with hydrogen chloride at room temperature (cooling with ice water) and kept in a well stoppered flask for 20 hours. It is then poured into water and the coumarin collected after an hour. One recrystallization from dilute alcohol is usually sufficient. This method avoids sulphonation of aromatic nuclei, prevents saponification of the beta-keto ester, gives an improved yield (90%) and purer products. In cases where little or no reaction can be obtained with concentrated sulphuric acid (phenol, beta naphthol, quinol), the new method also gives bad results.—HERBERT APPEL *J Chem Soc* (1935), 1031-1032 (G W F)

Heptane and Its Solutions—Chemistry of No 6 Solubility of the Halogens in Heptane The heptane was prepared from hydrocarbon of Jeffrey pine oil. Details of preparation are given and various experiments reported. Thirty experiments on solubility of chlorine in heptane are tabulated, showing temperature, grams dissolved, grams hydrogen chloride found in 100 cc of solution. Other tables show solubility of bromine and iodine. Reactibility with other elements was tried. Of the first group, lithium, sodium and copper were used. Over night, lithium and sodium almost completely disappeared. A solution of chlorine in heptane added to finely powdered copper reacted with phenomenon of flame. When solution was kept in an ice bath for several hours there was no flame but loss of color of chlorine indicated reaction. Flame is produced when chlorine gas is in contact with phosphorus, copper, boron and silicon in powder. Chlorine in heptane solution gives like phenomena with red phosphorus and powdered copper. Trial of chlorine hydrate upon red phosphorus and powdered copper gave negative results. Of the second group calcium, cadmium, magnesium and lead were tried. Calcium yielded bubbles with chlorine and bromine, magnesium and cadmium were little affected, lead decolorized all three. Of group three, aluminum was found to react with all three. References to earlier reports are appended.—JOSEPH SEMB *J Am Pharm Assoc*, 24 (1935), 547 (Z M C)

Iodoform and Thymol Iodide—Preparation and Properties of The pharmacopoeial requirements concerning iodoform, and its preparation from acetone, potassium iodide and sodium hypochlorite are dealt with. Illustrations of its different crystalline forms are given. Two methods of preparing thymol iodide have been investigated. It has been shown that the substance resulting from direct iodination is different from that produced when a hypochlorite is used as the intermediary. With the latter a certain amount of chlorination is also brought about. The B P C sets the standard of 40% iodine content, but some commercial samples fail to meet this requirement.—N GLASS *Pharm J*, 134 (1935), 785 (W B B)

Isopropyl Nitrite—Note on Isopropyl nitrite was tried as a substitute for sweet spirit of nitre because of the ease with which ethyl nitrite (the active constituent of sweet spirit of nitre) volatilizes. Isopropyl alcohol was tried because of its high purity, low cost, low toxicity and because it permitted extemporaneous preparation. The official method for ethyl nitrite invariably leads to the production of some acetaldehyde, using the same method but substituting isopropyl alcohol, appreciable quantities of acetone, a more undesirable by product, would be produced.—C L M BROWN *Pharm J*, 134 (1935), 793 (W B B)

Pharmaceutical and Phytochemical Products—Directions for the Preparation of The following products are discussed on the bases of (1) name, (2) chemical formula and molecular weight (3) raw materials (4) apparatus (5) time, (6) directions, (7) yield, (8) properties, (9) tests (10) chemical reactions involved and (11) references (a) paraformaldehyde (b) d glucose, (c) sodium thiosulphate, (d) zinc lactate, (e) milk sugar, (f) casein, (g) isoborneol (h) aconitic acid, (i) veratrol (j) mucic acid and (k) benzoyl peroxide.—C A ROJAHN *Apoth Ztg*, 50 (1935), 910-916 (H M B)

N-Phenyl-Piperazine—Derivatives of Although it is a cyclic compound, N phenyl piperazine, $\text{C}_6\text{H}_5\text{—}\begin{array}{c} \text{CH}_2\text{CH}_2 \\ \diagup \quad \diagdown \\ \text{CH}_2\text{CH}_2 \end{array}\text{—NH}$ first prepared in 1933 from aniline and dibromo diethylamine

shows the characteristic reactions of an aliphatic secondary amine. Physiologically, from experiments upon frogs and rabbits, it is found to provoke a reflex hypersensitivity analogous to that of strychnine. It reacts with ethylene oxide to form N-β oxyethyl-N'-phenylpiperazine, $\text{R—CH}_2\text{—CH(OH)—}$ which was identified by its salts and its acetyl and benzoyl derivatives. The benzoyl

derivative of the new alkylamine showed slight anesthetic properties With 40% formaldehyde the amine gave diphenylpiperazyl methane, RCH_2R , and with phosgene solutions the NN' -

diphenylpiperazine carbonyl, $RCOR$ ($R = C_6H_5N \begin{smallmatrix} CH \\ C_2H_2 \end{smallmatrix} N-$) It also reacts with a variety

of halogen compounds, including ethyl bromo acetate, benzyl chloride and 2,4-dinitro chlorobenzene The product with the last-named substance, phenyl- N -2,4-dinitro phenylpiperazine, $RC_6H_4(NO_2)_2$, is photo sensitive—V PRELOG and Z BLAZEK *Coll Czech Chem Communications*, 6 (1934), 549, through *Pharm J*, 134 (1935), 649 (W B B)

Picrotoxin—Part I The constitution of picrotic acid and the C skeleton of picrotoxin and picrotin is reported By applying the Dieckmann reaction to the ethyl ester of an acid, $C_{12}H_{14}O_4$, obtained by hydrolytic fission of picrotic acid, the beta ketonic ester (I) resulted Thus the acid must have the formula (II), indicating that picrotic acid must have the structure (III) rather than (IV), and the C-skeleton (V) for the lactones, picrotoxin and picrotin

DONALD MERCER, ALEXANDER ROBERTSON and ROBERT S CAHN *J Chem Soc* (1935), 997-1000 (G W F)

Potassium Guaiacol Sulphonate Though a very stable compound it is popularly believed to be absorbed as an entire molecule Guaiacol, the basic substance, has the following structure

With the above numbering of carbon atoms four guaiacol sulphonic acids are possible, the 1, 2, 3 the 1, 2, 4, the 1, 2, 5 and the 1, 2, 6 From each one of these acids, as well as by replacement of the H of the OH group, salts may be formed The only important sulphonates in the present consideration are those in which the metal enters the sulphonic acid group Much confusion has arisen in the nomenclature by different writers in the use of terms such as ortho, meta and others to indicate position of substituents The present investigation was prompted by the questions of difference in therapeutic activity, choice of most active form and distinguishing tests for it, and which form is most commonly sold Available literature yielded no thorough pharmacological study but references are made to reports that have been made tracing the history briefly The 1, 2, 6 compound

has been recognized by New and Nonofficial Remedies 1918 to 1934 editions, Svenska Farma kopen, 1925, Phar Hungarica, IV, 1934, British Pharm Codex, 1934, Deutsches Arzneibuch, prior to 1936, Merck's Index, IV, 1930 From the various sources studied, it is concluded that up to 1926, products on the market were mixtures of the 1,2,4 and the 1,2,5 compounds with varying amounts of the basic one It seems certain that the 1,2,6 compound has not been made Seven different sources gave substantially the same product Tests and data, upon which the conclusions are based, are enumerated The proportion of the 1,2,4 to the 1,2,5 is approximately 3 to 1 —A H CLARK and ERNST KIRCH *J Am Pharm Assoc*, 24 (1935) 564 (Z M C)

β -Santonin—Properties of β -Santonin, a stereoisomeride of santonin, has been obtained from samples of *Artemisia* from the N W Frontier of India, and occurs as colorless prisms m p 216–218° C, $[\alpha]_D^{19}$ $^{\circ}$ –137.2°, the oxime having m p 224° C On reduction with palladized charcoal and hydrogen in acetic acid, β santonin gives tetrahydro- β santonin m p 207–208° C, and tetrahydro β santonin-b, m p 125–126° C, both the above on reduction with zinc and hydrochloric acid give deoxytetrahydro β santonin, m p 75–76° C, and this substance on dehydrogenation with selenium gives 1 methyl 7 ethylnaphthalene β Santonin treated with sulphuric or hydrochloric acid forms *l* desmotrope β santonin m p 253° C, $[\alpha]_D^{20}$ $^{\circ}$ –101.7°, and this on treatment with potassium hydroxide gives *l*-isodesmotrope β santonin m p 194° C $[\alpha]_D^{20}$ $^{\circ}$ –136.8°, identical with *l*-desmotrope santonin obtained by treating santonin with sulphuric acid, reduction of this substance with zinc and acetic acid gives *d*-santonous acid, m p 177–178° C $[\alpha]_D^{22}$ $^{\circ}$ +75°, the ethyl ester having m p 117° C, $[\alpha]_D^{20}$ $^{\circ}$ +75° *l* Desmotrope β santonin reduced with zinc and acetic acid gives *d* β santonous acid, m p 174° C, $[\alpha]_D^{20}$ $^{\circ}$ +54.9°, and treatment of this acid with barium hydroxide gives a *d* β -santonous acid m p 152° C $[\alpha]_D^{20}$ $^{\circ}$ +60.9° together with 1,4 dimethyl β naphthol —G R CLEMO *J Chem Soc* (1934) 1343, through *Quart J Pharm Pharmacol*, 8 (1935) 264 (S W G)

Sapogenins—Spectrographic Observations on Various The absorption spectrograms of hederagenin, oleanolic acid and α ursolic acid are very similar and show neither maxima nor minima It is therefore difficult to distinguish these compounds by this means β -Ursolic acid is sharply differentiated from the α acid by its absorption spectrum which has 2 maxima between 3500 and 4000 μ Taraligenin has a curve identical with that of oleanolic acid Kotake reported that taraligenin and panaxsapogenin are identical, and Kitasato subsequently established the identity of panaxsapogenin with oleanolic acid But Winterstein supposed that taraligenin represented a mixture of oleanolic acid and hederagenin The authors subjected their taraligenin to fractional crystallization from chloroform methanol according to Winterstein, but obtained no hederagenin From their spectrographic examination as well as this result they believe that taraligenin and oleanolic acid are very closely related if not identical —S KUWADA and T MATSUKAWA *J Pharm Soc Japan*, 54 (1934), 32–34 (R E K)

Tannin Esters Water-soluble metal albumin tannin ester compounds are prepared by dissolving tannin esters (other than acetyltannin esters), which still contain free phenol groups and are saponifiable at ordinary temperatures by normal sodium carbonate solution only with difficulty, in such quantity of aqueous alkali or alkali reacting alkali salt that the solution is still weakly acidic and treating with aqueous metal albumin solutions The compounds are used therapeutically in solution or in powdered form Among examples henzoiltannin is made by heating a mixture of tannin sodium benzoicum and diphenyl ether in a water bath diluting largely with water, filtering, washing and vacuum drying at 30–40° A solution of the product is added to an aqueous solution of argemone proteum and the solution evaporated —H COHN and C SIEBERT *Brit Pat* 423 057 (Jan 24, 1935), through *Chem Abstr*, 29 (1935), 4524

Tiemann's Iron—Synthesis of Reaction of hypochlorous acid upon rhodinal resulted in the formation of hydroxy chloro rhodinal (I), treatment with acetone and an alkaline agent resulted in dimethyl hydroxy chloro undecenone (II), dehydration and cyclization accomplished by phosphoric acid in ether produced iron (III)

III

The synthetic product had a boiling point of 140° at 12 mm, density (15/15) = 0.940, $\alpha_D = -21$. The optical rotation is inverse to the natural product (+40, +33) —ALBERT VERLEY *Am Per-fumer*, 30 (1935) 235-236 (G W F)

BIOCHEMISTRY

Anterior Pituitary—Growth Hormone of A review of pertinent literature, with discussion —H N EVANS *J Am Med Assoc*, 104 (1935), 1232 (M R THOMPSON)

Anterior Pituitary and Anterior Pituitary-Like Substances A review of pertinent literature, with discussion —EMIL NOVAL *J Am Med Assoc*, 104 (1935), 993 (M R THOMPSON)

Biochemistry—Inorganic, Note on Of the ninety-two known elements, thirty six have been found associated in one way or another with some form of living matter. Biological elements are classified into certain groups, including in the first two groups invariable primary elements such as hydrogen, carbon, nitrogen and phosphorous, found in all forms of life and concerned with physical structure, and invariable secondary elements, calcium, magnesium, sodium, potassium, iron, sulphur and chlorine which occur in smaller quantities than those in the first group. Manganese is essential for farm crops and also for growth in milk-fed rats. Copper plays other parts in animal life besides association with hemoglobin, notably in pigments such as hemocyanin in molluscs and in the ink of the octopus, which is of melanin nature. It has also been suggested that copper is associated with the vitamin B complex in its action on the body. There is evidence that hormones may be associated with inorganic ions. The best known example is thyroxine with iodine. The intake of calcium and phosphorus plays an important part in the healing of rickets, it has been found that reducing the Ca/P ratio from 4-1 to 2-1 is equivalent to giving 0.7 unit of vitamin D. Also, there is a preference of high calcium diets over those of low calcium content for manifesting parathyroid activity. Magnesium appears to be connected with tetany, renal damage and the activation of the enzyme phosphatase —F J DYER *Pharm J*, 134 (1935), 563 (W B B)

Blood Urea—Estimation of Take 5 cc of oxalated blood (potassium oxalate), add 5 cc of 10% trichloroacetic acid. Centrifuge for three minutes at full speed or filter. Titrate 5 cc of the clear supernatant liquid with 5% mercuric chloride, using 20% sodium carbonate as indicator. Add mercuric chloride until one drop of titrated solution turns one drop of indicator brown in three seconds. **Calculation** Let x = number of cc of mercuric chloride used. Then $40x = 60 + y$ mg urea/100 cc of blood —C M DOUGLAS *Practitioner* (1935), 378, through *Pharm J*, 134 (1935) 423 (W B B)

Calcium—Availability of, in Foods Containing Oxalates A preliminary report of work to be undertaken on the occurrence of oxalates in foods and their effect in the diet of the rat —E F KOHMAN and N H SANBORN *Ind Eng Chem*, 27 (1935), 732 (E G V)

Calcium in Serum—Volumetric Determination of The 0.2 cc sample is treated with 0.5 cc of cold saturated ammonium oxalate solution, and, after standing over night, diluted with 1 cc of water and centrifuged for 15 minutes at 3000 r p m. The precipitate is washed three times with 3 cc of ammonia solution made by diluting 2 cc of concentrated ammonia to 100 cc. It is then dissolved in 0.5 cc of 4 N sulphuric acid on a water-bath cooled and treated with 2 cc of 0.001 N tetravalent cerium sulphate. After 3 minutes, a few drops of 1% potassium iodide solution are added and a little 0.25% starch solution and the mixture titrated with 0.001 N sodium thiosulphate containing 0.048% of sodium hydroxide. The cerium sulphate solution, which is preferred to potassium permanganate as a sharper and more accurate end-point is given, is prepared by dissolving 1 Gm of the finely powdered salt in 100 cc of water with 30 cc of concentrated sulphuric acid, and diluting to 750 cc. It is standardized against the 0.001 N thiosulphate, diluted to volume and restandardized —F RAPPAFORT and D RAPPAFORT *Mikrochemie* 15 (1934), 107, through *Quart J Pharm Pharmacol*, 8 (1935), 281 (S W G)

Follicle Hormone Derivatives Acyl octahydrofollicle hormones are obtained by treating the acyl derivatives of the isomeric dihydrofollicle hormones with hydrogen in the presence of catalysts, whereby 6 further hydrogen atoms are taken up by each molecule. The starting materials may be obtained by hydrogenation of the acyl derivatives of the follicle hormone. Among examples, (1) monobenzoyldihydrofollicle hormone in alcoholic solution is hydrogenated at 140° under 100 atmospheres pressure in the presence of a catalyst obtained by reducing a mixture of nickel oxide and copper oxide and (2) diacetyldihydrofollicle hormone is hydrogenated at 180° and 100 atmospheres in the presence of cyclohexanol and a nickel-chromium catalyst. The compounds obtained have a physiological effect similar to that of male sex hormone. The benzoyl derivative may be saponified to yield the octahydrofollicle hormone $C_{18}H_{30}O_2$ —SCHERING KAHLBAUM A G Brit Pat 423 287 (Jan 29, 1935), through *Chem Abstr*, 29 (1935), 4524

Hormones from Urine For concentrating sexual hormones in urine, the urine is substantially saturated with a highly soluble sulphate such as ammonium sulphate which is capable of producing a salting-out effect; the mixture is allowed to stand until it separates into two layers, and the supernatant layer, which contains substantially all the hormone in concentrated form, is recovered—H LANGECKER (to Schering-Kahlbaum A-G) U S Pat, 2,001,255 (May 14, 1935), through *Chem Abstr*, 29 (1935), 4524

Hormones in Pregnancy Urine—Investigation of the New Biologic Test for Kanter, Bauer and Klawan have recently (1934) reported experiments on a new biologic test for hormones in pregnancy urine in which they intimate the usefulness of the female bitterling in the diagnosis of pregnancy. They used the lengthening of the female ovipositor as a criterion of positive reaction, and suggested a method of standardizing the bitterling to avoid erroneous results. In the present study, the test consisted of placing a mature female bitterling in a 2 liter bowl containing 1500 cc of water. Six cc of the urine to be tested was added to each bowl. The fish were observed at 24-hour intervals for 72 hours. Elongation of the ovipositor to at least 25 mm was taken as a positive reaction, a length of 15 mm was considered a moderate enlargement (doubtful) about 10 mm was called slight enlargement (probably negative), and a negative reading was an ovipositor measuring 5 mm or less. Forty-six fish were placed in individual aquariums. Five groups of urine were tested. After 48 hours, most of the fish had either reacted positively, or not at all, and the 72 hour reading showed little or no variation from the 48-hour reading. Only 9 of 21 urines from pregnant women gave definitely positive reactions. Of 7 from normally menstruating non pregnant women, 4 gave positive reactions. One male urine of 4 tested was positive and a later specimen from the same male gave positive reactions in every one of the 6 fish tested. Urines from women who had passed the menopause were positive in 1 of 3 cases. Boiled urines from pregnant women were positive in some instances and negative in others. It was concluded that the biologic reaction is not a specific test for pregnancy. The studies are being continued—I S KLEINER, A I WEISMAN and H BAROWSKY *J Am Med Assoc*, 104 (1935), 1318 (M R THOMPSON)

Humoral Medicine and Chemistry The humors like the cells consist chiefly of colloids among which take place all vital reactions and phenomena of growth, nutrition and senility. The harmfulness of pathogenic agents is related to the production of plasmatic precipitates. In harmful colloidal reactions, the precipitates which are formed are flocculates, and it is by flocculation that the colloidal state (which governs life) is destroyed and this destruction produces disease and death. In many sick people humoral instability is a primary cause of flocculation, the latter then occurs at the slightest cause, and in order to cure such patients a greater stability must be imparted to their blood plasma. The means used to consolidate the colloidal state are few in number and were discovered empirically. To date one of the most remarkable, magnesium thiosulphate, proposed by the author, has been of inestimable value in this respect—AUGUSTE LUMIÈRE *14me Congrès de Chimie Industrielle, Paris*, Oct 21–27, 1934, 15 pp (A P-C)

Hydrochloric Acid—Determination of, in Stomach Contents. The author discusses the reaction of Gunzburg which has been used to determine the hydrochloric acid content of gastric juice. This is the phloroglucin hydrochloric acid reaction. The various concentrations of acid, the presence of other constituents in the gastric juice etc., are discussed especially as to their effect on the reaction. The author then suggests a new reaction. Two hundred mg of resorcin and 200 mg of vanillin are dissolved in boiling water. Upon cooling a portion of these substances crystallize out. This suspension of minute crystals is kept in a wide-mouth bottle through the cork of which a dropping tube is inserted. A drop of the reagent is evaporated to dryness. A drop

of the stomach content is then added to the residuc, the presence of hydrochloric acid causing a beautiful violet color. The reaction was obtained with normal gastric juice as well as with an artificial gastric juice having the following composition: 99% water, 0.3% pepsin, 0.15% NaCl, 0.05% KCl, 0.005% CaCl_2 and traces of phosphates and iron salts. Experiments were made with gastric juice containing a variety of concentrations of hydrochloric acid (0.03N, 0.02N, 0.01N, 0.005N, 0.0025N, 0.0015N). All concentrations of hydrochloric acid give a reaction except those of 0.0015N and less. Since the reaction is positive with concentrations above 0.0015N a rough estimate of the hydrochloric acid content in a given sample may be obtained by preparing a series of dilutions of the sample and submitting them to the test. All of the strong acids give a positive reaction; even boric acid gives a weak violet color. The organic acids react as follows: oxalic acid—a distinct color; malic and tartaric acid—a weak violet color; formic, acetic, propionic, butyric, caprylic, capronic, valeric, citric, cinnamic and lactic acids gave negative reactions. Since lactic acid occurs occasionally in the stomach in certain pathological conditions concentrations as high as 0.1 and 0.2N were tried. The result was negative. The obtaining of a violet color with the reaction then depends largely upon the presence of an inorganic acid, and the inorganic acid in gastric juice is hydrochloric acid.—M. WAGENAAR. *Pharm Weekblad*, 72 (1935), 837. (E. H. W.)

Insulin—Sulphur in In studying the constitution of insulin with respect to sulphur content, Freudenberg and Wegmann found that the compound was a protein containing two cystine residues in a peptide like structure to which were attached peripheral, apparently smaller sulphur-containing groups in disulphide formation. The molecule broke up into an SH compound (Ins SH) and a smaller fragment (HSR) when hydrogenation split the $-\text{S}-\text{S}-$ bond. Considering the intact insulin as Ins $\text{S}-\text{SR}$, it split into the inactive portions Ins SH + HSR. Oxidation of the hydrogenated insulin with hydrogen peroxide in the presence of cysteine gave a new, active, insulin like compound, represented by the structure Ins $\text{S}-\text{S}-\text{Cys}$. The HSR residue obtained by hydrogenation of insulin, therefore, was not cysteine. SH-Glutathione could be substituted for cysteine, but thioglycolic acid could not, indicating that the effect of cysteine and SH-glutathione was not due to their buffer action. Regeneration of insulin occurred under the above conditions after inactivation by alkali. Thus alkaline inactivation also involved hydrolysis of the $-\text{S}-\text{S}-$ group. This was further indicated by the liberation of hydrogen sulphide on acidification after alkaline treatment, and by the marked change in optical rotation on inactivation of insulin by hydrogenation or alkali. Ultraviolet irradiation inactivated insulin with evolution of hydrogen sulphide, and oxidation of the inactive product in the presence of cysteine gave an active compound again. Alkali inactivation also produced some ammonia together with hydrogen sulphide and this ammonia apparently was due to decomposition of insulin and did not occur as an impurity of the alkali. Other isolated facts about insulin were as follows: the van Slyke determination of free amino nitrogen was questionable since it is known that organic sulphur (cystine, thioglycolic acid) can reduce nitric acid to nitrogen and thus give high values; iodoacetic acid at pH 7.4 destroyed the activity of insulin so slowly that no reciprocal action with an SH-group was observed; hydrogen persulphide markedly and rapidly attacked the action of insulin, whether by oxidation or hydrogenation was not known, and gave a very toxic compound causing destruction of the skin and depilation at the site of injection; ketene also inactivated insulin. The molecular weight of insulin was apparently 9,000–18,000.—K. FREUDENBERG and T. WEGMANN. *Z. physiol. Chem.*, 233 (1935), 159, through *Squibb Abstr. Bull.*, 8 (1935), A-964.

Iron—Colorimetric Micro- and Submicro-Method for the Determination of 8-Hydroxy-quinoline which has met with such success in inorganic analysis has been adapted to the quantitative determination of small amounts of iron. The color obtained in alcoholic solution is very intense greenish black. Before the iron is precipitated, calcium is separated with oxalate. The determination itself is made in a photoelectric colorimeter.—LAVOLLAY. *Soc. Chim. Biol.*, 17 (1935), 432, through *Pharm Weekblad*, 72 (1935), 691. (E. H. W.)

Milks—Biological Equilibrium and Disequilibrium of Commercially Modified Cow milk, in spite of its low iron content and the rapid disappearance of its antiscorbutic activity under various commercial treatments for ensuring its preservation, constitutes a food of which the biological equilibrium can readily be brought out by experiments on pigeons. The unbalance of the biological equilibrium of milk powders increases with the degree of skimming of the milk. As carried out in the manufacture of condensed milks, addition of very large quantities of sugar upsets

the equilibrium of very high fat milks, on the other hand it compensates biologically a partial skimming Addition of whey, sugar and starches attenuates the biological disequilibrium of skimmed milk, especially of concentrated buttermilk —**RAOUL LECOQ** *14me Congrès de Chimie Industrielle, Paris, Oct 21-27, 1934* 5 pp (A P C)

Nutritive Value of Foods—Action of Some Commercial Practices on More or less prolonged action of a dry heat of 180° can change very considerably the nutritive value of foods, when, however, the change is confined to the sugar portion of a mixture (e g, caramelization), the change in nutritive value is less marked As practiced in the canning industry, a wet heat of 112° produces only a slight decrease in the vitamins B and C contents An alkaline reaction (e g, obtained by addition of baking powder) tends to increase the destruction of vitamins, while an acid reaction exerts a protective action —**RAOUL LECOQ** *14me Congrès de Chimie Industrielle Paris Oct 21-27, 1934* 5 pp (A P C)

Sex Hormones II Estrus-Producing Hormones Natural and synthetic compounds which can cause the production of estrus in addition to other activities of the female sex hormones are discussed Structural formulas for nine of the compounds are given indicating the relationship between their physiologic activities and chemical constitution —**C R ADDINALL** *Merck Report, 44 (1935)* 7 (S W G)

Sugar in Blood—Volumetric Determination of The method of Hagedorn and Jensen is adapted for use with one fifth the original quantity of blood or plasma The sample of 0.02 cc is carefully measured into Wassermann tubes containing 1 cc of N/50 sodium hydroxide, and 1 cc of 0.45% zinc sulphate solution is added to each tube These are heated in the water bath for 3 minutes, cooled and filtered into Hagedorn-Jensen tubes The Wassermann tubes are washed 3 times with 1 cc of hot water which is poured through the filter 2 cc of phosphate ferricyanide solution is added to each tube, and the mixture heated for 20 minutes in the water bath After cooling, 1 cc of a 2.5% solution of potassium iodide in 20% zinc sulphate is added followed by 1 cc of 20% phosphoric acid and a little 0.25% starch solution The contents are then titrated with 0.001N sodium thiosulphate containing 0.048% sodium hydroxide The phosphate ferricyanide solution is made by mixing just before use, equal parts of a 0.09% solution of potassium ferricyanide, and a solution containing 2.1% of secondary and 6.375% of tertiary potassium phosphate —**F RAPPAPORT and R PISTNER** *Mikrochemie* 15 (1934) 111, through *Quart J Pharm Pharmacol*, 8 (1935), 282 (S W G)

Testicular Hormone, Crystalline David, *et al*, have now prepared very active crystals from testicular extracts and suggested calling the crystalline preparation testosterone (I) I had an activity, compared to capon units of about 10 γ and had a uniform crystallographic structure as well as constant physical properties In the infantile castrated rat, I had a weaker action than an equivalent number of capon units of unpurified testicular extracts, and if a completely inactive extract prepared from testicles or other starting materials such as urine was injected with I, the relative growth of the seminal vesicles was the same as obtained with aliquot amounts of crude testicular extract Thus there must have been a second substance in the crude extracts which was an activator for I This was also true to a certain extent for dehydroandrosterone, but not for androsterone To illustrate the difference between I and androsterone, the melting points were 154-154.5° and 181-183° respectively, the specific rotation in alcohol, +109° and +96°, respectively, and the capon unit, +10 γ and 70-100 γ respectively —**K DAVID, E DINGEMANSE, J FREUD and E LAQUEUR** *Z physiol Chem*, 233 (1935) 281, through *Squibb Abstr Bull* 8 (1935), A 983

Urine and Blood Serum—Determination of Indoxyl Content of The author has applied the Heitz Boyer and Grigaut indoxymeter to the determinations obtaining satisfactory results using the Jolles reaction The apparatus contains glass tubes 14 mm in diameter and graduated into 5, 6, 16, 20 and 22 cc To the urine is added 10% of a solution of basic lead acetate and filtered Five cc of the filtrate is put into the tube which is then filled to the 6 cc mark with a 5% alcoholic thymol solution Hydrochloric acid (Sp Gr 1.17) containing 3 Gm ferric chloride per litre, is then added until the 16 cc line is reached After standing thirty minutes the tube is filled to the 22 cc mark with chloroform The tube is then shaken, allowed to stand five minutes and matched in the indoxymeter with the proper color disk When the indoxyl content of blood serum is determined, the serum is first treated with 20% of its volume of trichloroacetic acid and then the procedure above is followed —**A GRIGAUT** *Bull Biolog Pharm* through *Pharm Weekblad*, 72 (1935) 939 (E H W)

ANALYTICAL

Albumin Tannate The properties of various commercial albumin tannate preparations are compared with those of Tannalbin, Knoll The moisture content, water solubility, ignition residue, solubility in pepsin-hydrochloric acid and the solubility in 1.5% sodium carbonate of the residue not digested by pepsin hydrochloric acid as well as that of the substance *in toto* are reported The tested preparations display a number of differences from Tannalbin Different specimens of the latter product show some variability Albumin tannate preparations are less soluble in pepsin-hydrochloric acid and in sodium carbonate solution and have lower tanning content than the Tannalbin When made by the method of the Netherlands Phar., IV or V, albumin tannate is too soluble in pepsin-hydrochloric acid A substance with the desired properties may be prepared by increasing either the temperature to which the solution of tanning mixed with albumin is heated or by increasing the duration and temperature of the process of hardening Hardening of the dry material may be omitted if the solution is boiled for a couple of hours Of eight foreign (non-Danish) commercial albumin tannate preparations tested only one had properties sufficiently similar to those of Tannalbin to serve as a substitute —F REIMERS *Dansk Tids Farm.*, 9 (1935), 153 (C S L)

Alkaloid-Containing Poisonous Drugs—Detection of, in Powdered Drugs The following method is proposed Moisten thoroughly a triturate of the finely powdered drug and 2.0 Gm powdered slaked lime with 12 cc water extract the mixture in a small flask with 20 cc of 90% alcohol for 1 hour with vigorous shaking and warming on a water-bath separate the alcohol extract from the drug lime mixture by means of a small flat filter and wash the contents of the filter with 10 cc alcohol Evaporate the filtered extract and wash alcohol, take up the residue with 10 cc water and 3 drops of dilute sulphuric acid in the cold, filter the solution of fat resins and in soluble matter (calcium sulphate) through a small moistened filter and rinse the filter with some drops of water Divide the filtrate on 3 watch glasses and 2 small porcelain dishes, evaporate each to dryness and carry out the following precipitations and color reactions for alkaloids (1) Dissolve two of the residues on the watch glasses in some drops of water and treat one with some drops of tannic acid solution (German Phar VI, page 764) and the other with some drops of iodine potassium iodide solution (see German Phar VI under iodine solution page 765 and page 780) Gray brown or red brown amorphous precipitates indicate the presence of alkaloids Take up the residue in the third watch glass with some drops of water and a drop of dilute sulphuric acid and add two drops of potassium-mercuric iodide solution In this case the usual Mayer's reagent is not employed but Boehm's reagent, a highly concentrated solution of red mercuric iodide in concentrated potassium iodide solution in such proportions that the formula is $2KI \cdot HgI_2$ and is prepared by dissolving 33.11 Gm potassium iodide and 45.28 Gm mercuric iodide in 33.11 Gm water with some shaking (specific gravity 2.1694 at 15° C) This reagent yields with bases containing trivalent amino nitrogen white yellow precipitates and with quaternary ammonium bases of pentavalent-nitrogen highly colored yellow precipitates (2) the residues in the porcelain dishes are subjected to the following color reactions (a) Take up the residues with 2-3 drops of concentrated sulphuric acid which might not be colored characteristically If it remains colorless add to one dish some particles of fine sugar whereby characteristic colors might appear (b) Scatter a trace of finely powdered potassium dichromate which produces at the most a weak green color caused by the chromic sulphate formed in closing single small crystals but not colored streaks flowing from the crystals or odors like benzaldehyde cumarin spirea or the like In cases of positive reactions a microscopic examination of the drug will give a clearer idea of the nature of the alkaloidal admixture —H KUNZ KRAUSE *Apoth Ztg.*, 50 (1935) 862-864 (H M B)

Alkaloids—Determination of, in Injectable Solutions All of the common alkaloids used in solutions for injection were studied to determine the best methods of assay Results were as follows Adrenaline gives most accurate results when determined by the described Atherton Seidele colorimetric method or by the photometric method, atropine by titration with periodic acid, caffeine by iodometric determination, cinchonine by gravimetric method, emetine by titration with acid novacaine by retitration after titration with acid, pilocarpine by iodometric determination quinine by colorimetric determination, sparteine by retitration, strychnine by use of periodic acid, yohimbine by retitration —G N THOMAS and D JATRIDES *J pharm chim.*, 21 (1935) 585 (M M Z)

Alkaloids—Rotatory Power of Various Rotatory powers of the various alkaloids included in the French Codex (except quinine and its salts) were determined for the yellow sodium line and for the yellow, green, blue and violet mercury lines, as follows

Alkaloid	Yellow Sodium α 5893	Yellow Hg α 5780	Green Hg α 5400	Blue Hg α 4358	Violet Hg α 4046	$\alpha_{5400}/\alpha_{5780}$

CH LORMAND and P GESTAU *14me Congrès de Chimie Industrielle, Paris* (Oct 21-27, 1934), 3 pp (A P C)

Anesthetics With Special Reference to Cocaine and Novocaine in Illegal Trade This paper is one of a series covering the detection of cocaine in combination with other anesthetics, in which combinations it often appears in illegal traffic. Several of these papers published in the *Pharm Weekblad* in 1934 are abstracted in the *YEAR BOOK of the AM PHARM ASSOC*, 23 (1934). The paper outlines a general scheme for the examination of samples: (1) the numbing effect as well as (2) the taste (tasteless, bitter, sour) should be observed. (3) The general appearance is of importance. The following anesthetics are amorphous: Acoine-HCl, alypine, orthoform N, propaesine and tutocaine. The following appear amorphous but are also hygroscopic: Allylcocaine HCl (nycaïne), psicaïne new (tartrate). The following are granular: Cocaine HNO₃, psicaïne, eucaine A and B, butelline and subcutine. The following exhibit beautiful crystals: Cocaine-HCl (highly refractive), larocaine, novocaine, ecognine and benzoecognine. The following occur in finer crystals: Pantocaine, stovaine and tropacocaine and in very fine crystals: Alypine nitrate, holocaine, anaesthesine, psicaïne-new-HCl, orthoform and cycloform. The following show a tendency to clump together: Allylcocaine nitrate, diocaine and percaïne. (4) With reference to the reaction toward litmus paper the following show a neutral reaction: Alypine nitrate, butelline, diocaine, eucaine-A, eucaine B, novocaine, nycaïne, orthoform, orthoform new, percaïne, propaesine and tropacocaine and the following show a weakly acid reaction: Acoïne, allylcocaine nitrate, alypine (very weak), anaesthesine, cocaine-HCl and cocaine-HNO₃, cycloform (very weak), larocaine, pantocaine, psicaïne, psicaïne-new-HCl, psicaïne new-tartrate, tutocaine, stovaine (weakly acid toward Congo paper), subcutine (strongly acid) and holocaine (alkaline). (5) The solubility in water is often an indication of identification. The following are easily soluble in water: Allylcocaine nitrate, alypine-HCl, alypine nitrate, cocaine HCl, larocaine, novocaine, nycaïne, pantocaine, percaïne, psicaïne, psicaïne new-tartrate, psicaïne-new HCl, stovaine and tropacocaine. The following are fairly soluble in water: Acoïne, butelline, cocaine-HNO₃, diocaine, eucaine-B, tutocaine. The following are poorly soluble in water: Anaesthesine, cycloform, eucaine-A, holocaine, orthoform, orthoform new, propaesine and subcutine. (6) Eucaine-A is insoluble in alcohol and holocaine, psicaïne, tutocaine, tropacocaine and novocaine are slightly soluble in alcohol. (7) The following are only slightly soluble in 0.5 N hydrochloric acid: Diocaine, holocaine, psicaïne-new-HCl, tropacocaine and cocaine-HNO₃. (8) Reactions for acid radicals are as follows: Butelline gives a reaction for SO₄; allylcocaine nitrate, alypine nitrate, cocaine nitrate and novocaine nitrate give reactions for NO₃; psicaïne and psicaïne new give reactions for tartaric acid, subcutine gives a reaction for sulfophenylic acid. The following give no reaction for acid radicals: Anaesthesine, cycloform, orthoform, orthoform new and propaesine. The remaining anesthetics give reactions for Cl⁻. (9) With the reaction with potassium dichromate and strong hydrochloric acid, primary aromatic amines give a purple color, the benzoyl group gives a yellow resin and pantocaine gives a greenish resin accompanied by a considerable odor. (10) The lignin test (with paper) on primary aromatic amines shows the following reactions: without acid, very good—anaesthesine

and subcutine without acid good—orthoform and orthoform-new without acid fairly good—cycloform and propasine with acid very good—anæsthesine, subcutine, orthoform, orthoform new, cycloform and propasine, with acid fairly good—butelline, larocaine, novocaine and tutocaine (11) The reaction of Denigès-Marquis All phenols are colored at temperatures below 100° Orthoform, orthoform new, subcutine and ecgonine The following phenol-ethers react Acoine, diocaine holocaine (after 24 hours), percaïne, anæsthesine, cycloform and propasine Reactions on the benzoyl group (Denigès) are given by the following Allylococaine nitrate alypine, benzoylcegonine, cocaine-HCl, eucaine A, eucaine-B, nycaine, psicaine, psicaine new-HCl, psicaine new-tartrate, stovaine and tropacocaine Alypine-nitrate and cocaine nitrate do not give a reaction (12) The following reactions are given with ferric chloride Orthoform becomes violet-yellowish brown dirty green, orthoform-new becomes green violet-yellowish brown and subcutine becomes purple Among the phenols and phenol ethers, acoine becomes reddish brown, ecgonine red diocaine brown holocaine brown and percaïne yellowish brown (13) Two tables of melting points for 38 anæsthetics are given, one alphabetical and one according to melting points (14) Optical rotation is also of importance Tables for $[\alpha]_D^{20}$ are given The series of papers is to be continued —C OFFERHAUS and C G BAERT *Pharm Weekblad*, 72 (1935) 801 (E H W)

Argyrol, Collargol, Electargol and Protargol—Reactions for the Differentiation of (1) Mix 2 cc of a 0.5% solution of chromic acid with 7–8 cc of the dilute solution of the silver preparation and add 0.5 cc of a saturated sodium bicarbonate solution Argyrol first flocculation, later a clear yellow color Collargol a reddish precipitate Electargol like collargol Protargol like argyrol but more turbid (2) Mix one cc of 10% sodium thiosulphate solution with 9 cc test solution and add phenolphthalein Argyrol dark yellow color turning black Collargol and electargol violet to black precipitate Protargol Pink to red color (3) Mix 0.5% solution of chromic acid with nitric acid and add the silver preparation Electargol the yellow liquid turns slowly to blue The other compounds do not give that reaction (4) Picric acid precipitates the latter three compounds —CH VAILLE *Rev centro estud farm bioquím*, 25 (1935) 247 (A E M)

Atropine—Study of Commercial Drugs Containing Fifty-seven atropine containing commercial preparations were assayed by observing the dilatation produced in the pupil of the white mouse Most of the preparations were also assayed chemically Comparison of the two methods indicated whether the preparations contained pure atropine (I), hyoscyamine (II) or a mixture thereof II has 2.23 times the mydriatic effect of I in mice by subcutaneous injection A 1% aqueous solution of I-sulphate kept for 2.5 months at room temperature in the dark lost 20% of its activity A 1-mg % aqueous solution kept in an incubator at 37°, was found to be inactive after 4 months —H A OELKERS and E VINCKE *Arch expl Path Pharmacol*, 178 (1935) 439, through *Squibb Abstr Bull*, 8 (1935), A 968

Azulenogenic Sesquiterpenes—Color Reaction of The greenish blue color reaction given by Bourbon geranium oil and imperfectly purified rhodinols with a chloroformic solution of bromine is due to an azulenogenic sesquiterpene which can be isolated from geranium oil, and which boils under 5 mm pressure at 117° to 120° has a refractive index at 20° of 1.5021, specific gravity at 15° of 0.9134, rotatory power (in a 1 dm tube) of +11.40° (the sign of rotation was probably reversed by heating with boric acid to fix and separate the alcohols) and molecular refraction 66.2 (calculated 66.13) Azulenogenic sesquiterpenes are very widely distributed in nature they are present in a large number of essential oils in which they can readily be detected by the chloroformic bromine test —SÉBASTIEN SABETAY and HERMINE SABETAY *14me Congrès de Chimie Industrielle, Paris* (Oct 21–27 1934), 3 pp (A P C)

Bath Preparations XIV Fifteen commercial preparations are tested and studied from the following points (1) manufacturer, (2) how packed (3) price (4) physical properties, (5) reaction (6) dry residue, (44–91.9%), (7) mineral matter (1.2–15.7%) (8) sulphur dioxide (4 positive), (9) Hirst-Prokter reaction (4 positive) (10) 5 volatile oil (0.2–2.5%, 2 negative), (11) appearance under the ultraviolet lamp (12) appearance of the capillary streak in ordinary and ultraviolet light and (13) appearance and color of the aqueous solution (1.10) A second table lists a pine needle bath a ladies' bath rheumatism, morning evening and children's bath giving (1) appearance (2) odor, (3) specific gravity (4) dry residue (5) mineral matter, (6) % volatile oil (7) special properties and value and (8) chief constituent —W PEYER *Apoth Ztg*, 50 (1935) 658–661 675–678 (H M B)

Bath Preparations—XV Foot Baths Twelve preparations were examined and reports made with regard to (1) manufacturer, (2) price, (3) physical properties and (4) qualitative and quantitative analysis—W PEYER and R STADLER *Apoth-Ztg*, 50 (1935), 924-927

(H M B)

Bellier Number—Study of Its Use for the Detection of Peanut Oil in Olive Oils The following definition is proposed for the Bellier number the temperature of initial crystallization of the solid fatty acids of a fat or oil in alcoholic solution, when the solution is subjected to progressive cooling with constant agitation. A recommended technique for carrying out the test is described in minute detail, more particularly as regards the cooling, it is essentially as follows to 1 cc of well clarified oil or fat in a 26-27-mm by 22 cm test-tube add 5 cc of alcoholic potash (75 Gm per l), saponify by careful heating using an air-cooled reflux condenser, cool to 30° to 35°, add 1.5 cc of 1 + 2 acetic acid and 50 cc of 70% alcohol, close the tube with a rubber stopper carrying a semi-precision thermometer graduated from 0° to 60° or 0° to 100° and note the temperature at which the solution becomes cloudy due to crystallization. The test may be repeated on the same portion of sample, but in order to obtain concordant results the temperature must be raised each time about 15° to 20° above the clouding point. The precautions which must be taken in the preparation of the reagents and in the manipulative operations are described. The Bellier number of peanut oil is generally given as 40° to 41° and that of pure olive oil as 11.8° to 14.5°. Examination of a number of oils of known purity gave values of 9.5° to 18° the high values being obtained with Tunisian and Moroccan oils, oils obtained by extraction of press cake gave values of 9° to 16.5°. For the detection of peanut oil in doubtful cases, mix 9 parts of sample with 1 part of peanut oil (both by weight) and determine the Bellier number, with pure olive oil the value will not exceed 20° (except in extremely rare instances). By drawing a curve of the Bellier number of mixtures of peanut and olive oils, admixture of olive oil in peanut oil can also be detected and estimated quantitatively. If a mixture of 9 parts of the supernatant oil of canned fish and 1 part of peanut oil gives a Bellier number above 19.5°, the presence of peanut oil in the canning oil is indicated. As the Bellier number depends on the solid acids of oils, it might be deduced that its value was proportioned to the solid acids content of olive oils, with the proviso that the oils compared contain solid acids of the same type, of which there are two acids separating as arborescent crystals and giving lead salts that are completely soluble in warm ether, and acids separating as glomerule shaped crystals giving lead salts that are only partially soluble in warm ether. Some olive oils contain practically exclusively one or other type of acids while others contain both. As the solid acids are insoluble in 70% alcohol, it is suggested that they might be separated by the technique of the preparation of the Bellier test followed by cooling overnight at 10° to 12° and then for 1 hour at 5°, centrifuging, filtering and determining the acids by weighing or acidimetric titration. The quantitative composition of a mixture of solid acids, the nature of which is known could be obtained by determination of the Bellier number and comparing with curves prepared from the Bellier numbers of known mixtures of the same acids. Oils extracted from olive press cake when subjected to the Bellier test and then allowed to stand overnight at 20° to 25°, contain a suspended flocculent precipitate which gradually gathers at the top of the liquid. This test, though possibly not absolutely specific, is very characteristic and permits of detecting the addition of from 5 to 20% (according to the origin) of such extracted oil in pressed oil—R MARCILLE *14me Congrès de Chimie Industrielle, Paris* (Oct 21-27, 1934), 13 pp

(A P C)

Benzene—Ultra-Violet Absorption Spectrum of Utilization for the Detection and Determination of Small Amounts of Benzene in the Atmosphere The benzene is absorbed by passing the dried atmosphere through 95% alcohol at -85°. The absorption spectrum curve is obtained by Fabre and Amy's technique of the unbricated spectra method. As little as 0.1 mg benzene per liter of air can be determined with an accuracy of about 5% (in absence of homologs) on a 1-liter sample. The method is absolutely specific. The method is sensitive to about 1 part benzene in 100,000 parts of alcohol—PIERRE LAURIAN *14me Congrès de Chimie Industrielle, Paris* (Oct 21-27, 1934), 6 pp

(A P C)

Benzoic and Cinnamic Acids—Identification of, in Microsublimates of Balsams and Resins The recognition is accomplished by the addition of 4-5 drops of dilute sulphuric acid and then some sodium amalgam to a portion of the sublimate when benzoic acid is reduced to benzaldehyde. For cinnamic acid, a portion is treated with chromic acid or permanganate to oxidize it to benzaldehyde. The benzaldehyde is precipitated in a hanging drop slip containing *p* nitrophenylhydra-

zine (freshly prepared saturated solution in 15% acetic acid) The melting point of the hydrazone is 190–192° C The reaction is sensitive to 10 micrograms of benzoic acid and 20 micrograms of cinnamic acid —R FISCHER *Pharm Zentralh*, 76 (1935) 345 (E V S)

Bismuth—Assay of National Formulary Preparations Containing Report is made of a study undertaken to determine whether the method of assay used for the glycerite might be applied to determination of bismuth content of Solution of Bismuth, Elixir of Bismuth, Elixir of Pepsin and Bismuth and Elixir of Pepsin, Bismuth and Strychnine and also whether other methods could be used advantageously Reference is made to the various methods which have been used for the quantitative determination of bismuth In the present investigation a comparative experimental study of the official sulphide method, of the Mayer phosphate method and of the Schoeller and Waterhouse phosphate method was undertaken Detailed procedures are given Two samples of each preparation were assayed by each of two different people by the sulphide method and the Mayer phosphate method The Schoeller-Waterhouse phosphate method was abandoned because it seemed to yield slightly high results Either the sulphide method or the Mayer phosphate method yields accurate and comparable results when applied to glycerite, solution or elixirs of bismuth Since the Mayer phosphate method is simple and accurate it might well replace the sulphide method now official for the glycerite and be made official for the solution and elixirs —GLENN L JENKINS and SYLVIA MILLETT *J Am Pharm Assoc*, 24 (1935), 561 (Z M C)

Borax-Glycerin-Water Solutions—Reactions of When glycerin is added to a solution of borax a portion of the boric acid is converted into boroglycerin The conversion is dependent upon the concentration of the glycerin The reaction increases in acidity with an increase of free boroglycerin With a certain concentration of glycerin the amount of free boroglycerin should be just sufficient that the acidity of the solution will neutralize the alkalinity of the borax In order to determine which concentration of glycerin in combination with a concentration of borax will react neutral, the author made the following determinations

Percentage of Glycerin in the Solution		(2%)	Percentages of Borax (6%)		(10%)
85.8	pH	4.8	4.9		5.0
60	pH	5.25	5.4		5.45
40	pH	5.75	5.9		6.05
30	pH	6.10	6.25		6.45
20	pH	6.55	6.75		7.05
10	pH	7.25	7.60		8.0
5	pH	7.90	8.3		8.7
0	pH	9.2			

These determinations, made at about 15° show that a 20–25% solution of glycerin in borax solution reacts neutral —P VAN DER WIELEN *Pharm Weekblad* 72 (1935), 877 (E H W)

Bromides—Detection of Small Quantities of, in Sodium Chloride Mix 10 cc of water with one drop of a saturated solution of fuchsine and add drop by drop a solution of chlorine in water Note how many drops are needed to destroy the red color For the test use 10 cc of a saturated solution of the sodium chloride Add a drop of fuchsine solution and the double quantity of chlorine water then determined A reddish tint turning violet indicates bromine The reaction is sensitive to 0.1 mg potassium bromide —R CASARES LÓPEZ *Farm Moderna*, 46 (1935), 55 (A E M)

Bromine—Electrometric Determination of, in the Presence of Large Amounts of Chlorine The method permits the determination of 0.24 mg bromine in the presence of large amounts of chlorine Chlorides are removed by means of acetone The analysis of aqueous solutions is relatively simple, but it is applicable also to biological substrates after removal of proteins, this being effected by moist incineration The reduction of silver chloride and bromide by means of sodium amalgam produces a rapid and complete conversion of the halogens to soluble sodium salts The lower limit of bromine detected in tissue by this method was 5 mg % —G E VLADIMIROV and J A EPSTEIN *Mikrochemie*, 18 (1935), 58 (L L M)

Butterfat—Determination of, in food A method was proposed for the isolation of fat A weighed amount of paraffin equivalent to about one-third the weight of fat expected is added to the sample and the mixture hydrolyzed with hydrochloric acid Filter cell and ice water are added and the mixture filtered through linen coated with filter cell in a Buchner funnel The

precipitate is transferred to a beaker, dried, pulverized and treated with anhydrous sodium sulphate and petroleum ether and the extract filtered through asbestos in a Knorr tube. Four extractions are made and the combined filtrates evaporated to dryness and weighed. Correction is made for the added paraffin. Advantages cited are: the fat is extracted from the dried material with a single solvent, emulsions are avoided and the use of larger quantities of materials are possible. F. HILLIG, *J. Assoc. Official Agr. Chem.*, 18 (1935), 454. (G. S. W.)

Cæsium—New Spot Reaction for Gold and platinum bromides yield with cæsium salts a black precipitate useful in the detection of cæsium by the spot method. Analysis of the black triple salt indicated the formula $\text{Cs}_2\text{Au}_2\text{PtBr}_{12}$. For the detection of small quantities of cæsium in the absence of rubidium the use of concentrated reagents is recommended. If rubidium is present the best results are obtained with a solution containing 3% gold and 1.5% platinum. A drop of the reagent is touched to a piece of paper and to the spot is added a drop of the test solution. In the presence of cæsium, a gray to black spot is produced. 0.25 γ per cu. mm. can be detected. With the exception of rubidium in concentrations above 2%, the chlorides of rubidium, potassium, sodium, lithium and ammonium do not interfere. Cæsium may be estimated quantitatively by the spot method with an accuracy of 5–10%. —E. S. BURKSER and M. L. KUTSCHMENT, *Mikrochemie*, 18 (1935), 18. (L. L. M.)

Caffeine—Determination of, in Decaffeinated Coffees. The following method is recommended. Mix 50 Gm. of ground, roasted decaffeinated coffee with glass wool cut into short lengths, introduce directly into a Soxhlet extractor between two wads of glass wool (avoid packing tightly), extract for 5 hours with slightly moist chloroform, adding during the first and third hours 3 cc. of 20% ammonia when the extractor has just been siphoned, evaporate to pasty consistency on the water-bath (using suction to remove the last trace of solvent), add successively 75 cc. water, 20 cc. of 10% sulphuric acid and 1.5 Gm. of paraffin having a melting point of 60° to 62°, heat 20 minutes on the water-bath with occasional stirring, let stand over night in the refrigerator at 5°, filter in the refrigerator, make the filtrate alkaline with ammonia and evaporate to dryness on the water bath, break up the residue with a nickel spatula, take up 4 times with anhydrous chloroform, filter, evaporate to dryness on the water-bath, dissolve in 30 cc. of boiling water, add 1% potassium permanganate solution to permanent violet coloration, let stand on the water-bath 15 minutes (adding permanganate if the color disappears), discharge the color by dropwise addition of 3% hydrogen peroxide containing 1% of acetic acid, filter if necessary, extract with 4–30 cc. portions of pure chloroform (recovered chloroform is not advisable), evaporate the chloroform, dry at 90° to 100° for 15 minutes and weigh. Duplicate determinations agree within 1 mg. (on a total weight of 12 to 20 mg.). The caffeine obtained is white, fairly pure and melts at 220° to 225° (Maquenne block). If the technique is not strictly followed, there may remain small amounts of fat, which can be eliminated by another permanganate purification, this produces a loss of 1 to 1.5 mg. of caffeine which should be corrected for. —A. FAURE and R. PALLU, *14me Congrès de Chimie Industrielle, Paris* (Oct. 21–27, 1934), 4 pp. (A. P.-C.)

Carbon and Hydrogen—Preheater for the Microanalytic Determination of. A description of the apparatus with diagram. —W. F. BRUCE, *Mikrochemie*, 18 (1935), 103. (L. L. M.)

Carbon Dioxide—Determination of, in Confined Atmospheres. The principle of the method consists in shaking a given volume of the atmosphere with a hydroalcoholic solution of rosaniline decolorized by hydrazine, and comparing the color with those obtained by similar treatment of samples of known carbon dioxide contents. To simplify the method from the standpoint of sanitary control, comparison may be made with the color obtained with an atmosphere having a carbon dioxide content that is at the limit of safety. —RENÉ DUBRISAY and LÉON GION, *14me Congrès de Chimie Industrielle, Paris* (Oct. 21–27, 1934), 2 pp. (A. P.-C.)

Charcoal—Activated. Demand for a charcoal with greater adsorptive powers was responsible for the study reported. Adsorbent carbons may be produced in several ways, one of the most promising being that of carbonizing sulphite waste liquor from the pulping of wood for paper. Activation is usually resorted to, this usually involving some chemical treatment. A number of tests for purity, that is freedom from toxic or inert substances are given. The German Phar has a carbon with an adsorption capacity of 0.525 Gm. of methylene blue per Gm. of carbon. The Swiss Phar has one with capacity of 0.24 Gm. of methylene blue per Gm. of carbon. Saturation of carbon is best obtained by reliance on the mass effect of an excess of dyestuff. The following is the method finally decided upon: "Dissolve 0.25 Gm. of methylthiourea chloride (methyl-

ene blue) in enough distilled water to make 250 cc of solution. Measure exactly 50 cc of the solution, at 25° C, into each of two 100 cc glass stoppered flasks. To one flask add exactly 0.25 Gm of Activated Charcoal, stopper the flask and shake vigorously for five minutes. Filter the contents of each flask through a filter which has not been previously moistened, rejecting the first 20 cc of each filtrate. Measure exactly 25 cc of each remaining filtrate into 250 cc volumetric flasks. Add to each flask 50 cc of a solution of sodium acetate (1 in 10) and mix thoroughly, then add from a burette 35 cc of *N/10* iodine, keeping the mixture in constant rotation. Stopper the flasks and allow them to stand for fifty minutes, shaking vigorously at intervals of ten minutes. Dilute each mixture to exactly 250 cc with distilled water, mix thoroughly, allow to stand for ten minutes and filter each through a filter that has not been previously moistened, rejecting the first 30 cc of each filtrate. Determine the excess of iodine in 100 cc of each filtrate by titration with *N/10* sodium thiosulphate. The difference between the two titrations multiplied by 5, amounts to not less than 3.5. An important use of activated carbon is thought to be adsorption of gaseous products of fermentation or putrefaction and experiments led to adoption of the following: "Into each of two flasks place 185 cc of distilled water and 5 cc of glacial acetic acid and mix thoroughly. By means of a pipette add to each flask 10 cc of a solution of 2.5 Gm of crystallized sodium sulphide in 100 cc of distilled water placing the tip of the pipette at the bottom of the flask during delivery. Rotate the flask gently for thirty seconds, add to one of the flasks 1 Gm of Activated Charcoal, stopper the flasks and shake them for five minutes. Filter the contents of each flask through a filter that has not been previously moistened, rejecting the first 20 cc of each filtrate. Titrate 100 cc of each subsequent filtrate with *N/10* iodine using starch T.S. as the indicator. The filtrate from the Activated Charcoal consumes at least 5 cc less of *N/10* iodine than the filtrate from the solution to which no Activated Charcoal was added." Response of charcoals to the proposed tests to be included in U.S.P. XI is given for sixteen different carbons—JOSEPH ROSIN, GEO. D. BEAL and CHESTER R. SZALKOWSKI. *J. Am. Pharm. Assoc.*, 24 (1935) 630.

(Z. M. C.)

Chaulmoogra Oil in the Pharmacopœias and in Commerce. The lower limit of acidity and the upper limit of optic rotation should be suppressed. A 10% solution of 10 Gm oil in a total volume of 100 cc in chloroform investigated with sodium light should give, at room temperature in a 10 cm tube, a rotation of 5°12'—A and C. CHALMETA. *Farm. Moderna*, 46 (1935), 63 and 94.

(A. E. M.)

Chloral Formamide—Melting Point of. The melting point of Chloral Formamide B.P.C. is given as between 114° and 115° C, which is the same as that in the B.P. 1914. However, as the result of several experiments the authors recommend that the melting point should be recorded as 124° to 126°, with limits for pharmaceutical purposes between 122° and 126°. In determining the melting points, the values given are the mean temperature of melting, the transition range in most instances being one to two degrees. It is suggested that the recorded melting points represent the temperature of sintering possibly of impure material—C. T. BENNETT and N. R. CAMPBELL. *Pharm. J.* 134 (1935), 795.

(W. B. B.)

Chloroform and Carbon Tetrachloride—Differentiation between. The author comments on the recent article of Rozeboom (*Pharm. Weekblad*, 72 (1935), 689) in which a reaction depending upon the solubility of papaverine hydrochloride in chloroform is used to differentiate between chloroform and carbon tetrachloride. Quinine sulphate may be employed in similar manner. The author suggests the two following reactions for distinguishing between chloroform and carbon tetrachloride: (1) *Positive for Chloroform*—When boiled with Fehling's solution the sample with the chloroform will show reduction that with the carbon tetrachloride will not. (2) *Positive for Carbon Tetrachloride*—Heat 1 drop (no more!) in a test-tube lightly closed with a cork. The vapors will be oxidized by the air. Only carbon tetrachloride will liberate chlorine (CoCl₂). After cooling shake with a few cc of water and add potassium iodide starch solution. A blue color will result—N. SCHOORL. *Pharm. Weekblad*, 72 (1935), 751.

(E. H. W.)

Chromatographic Adsorption Analysis in Pharmacy. Rum was colored with caramel and then allowed to run through a vertical column of a suitable adsorbent (aluminum oxide). Untreated rum left its coloring matter on the top layer of the aluminum oxide, the rest of the column remaining perfectly white. The rum colored with caramel produced more or less faded zones throughout the entire column. The filtrate was practically colorless. One half per cent solutions of natural and synthetic balsam of Peru in alcohol and in petroleum ether were prepared. They

were treated as described above. The results show that the constituents in the natural and synthetic balsams are not the same, being retained differently by the aluminum oxide. Colorless constituents of preparations may in some cases be brought to view by examination of the aluminum oxide column under a quartz analysis lamp. Official tincture of digitalis prepared with absolute alcohol was compared with a tincture prepared with diluted alcohol. Marked differences are apparent in the appearance of the aluminum oxide column. A review of the literature of adsorption analysis is given.—VALENTIN *Pharm Ztg*, 80 (1935), 469 (G E C)

Citronellal—Determination of, in Java Citronella Oil Dutch Standard Method. The following method will be used as a standard for the determination of citronellal in Java citronella oil. Into a 150 cc flask weigh accurately about 2 Gm of Java citronella oil, add 10 cc of 95% alcohol and 20 drops (1 cc) of 0.1% alcoholic bromophenol blue solution and make neutral with 0.1N potash. To the neutralized liquid add from a burette or an automatic pipette 20 cc of 0.5N alcoholic potash and immediately afterward from a measuring glass 20 cc of a 5% alcoholic hydroxylamine hydrochloride solution. Shake, allow to stand at room temperature for an hour (under European conditions, at the much higher temperature in the Dutch East Indies a quarter of an hour is quite sufficient) and titrate the excess of potash with about 0.5N (alcoholic) hydrochloric acid, until the color of the indicator changes to greenish yellow, comparing the color with that of a blank determination made in the same way. The result is calculated from the following formula:
$$\text{per cent of citronellal} = \frac{(b-a) \times n \times 15.4}{g}$$

where b = volume in cc hydrochloric acid required for blank determination, a = volume in cc of hydrochloric acid required for titration, n = normality of hydrochloric acid and g = weight, in grams, of oil taken.—ANON *Perf Ess Oil Rec*, 26 (1935), 253 (A C DeD)

Cocaine—Separation and Detection of, in Mixtures of Cocaine and Procaine Two methods are given for the separation and identification of small quantities of cocaine-HCl when a large amount of procaine-HCl is present. One method is given for the detection of small quantities of cocaine, free base, when a large amount of procaine, free base, is present. One method is given which is suitable for estimating within 4 mg the amount of cocaine or cocaine-HCl present in a mixture of procaine, free base or salt, and cocaine, free base or salt. All of these methods are based on the fact that a buffer of proper acidity will cause the formation of a water-soluble salt of procaine and will not affect cocaine. All methods given separate the cocaine as the free base and do not affect its molecular structure, thus permitting the identification of pure cocaine and not its decomposition products.—C H RILEY *Am J Pharm*, 107 (1935), 270 (R R F)

Cod Liver Oil—Determination of, in Emulsions Weigh exactly 2 Gm of emulsion in a 50-cc beaker and add 8 cc of 10% hydrochloric acid. Cover the beaker with a watch glass and heat for a half hour on a water-bath. Agitate the contents for a quarter hour, then transfer the liquid with 10 cc of alcohol into a graduated vessel, shake vigorously for one minute and leave until it separates into two layers. Fill up nearly to the top graduation with petroleum ether, shake for a half minute and allow to stand for one hour. Withdraw 40 cc of the solution with a pipette into a tared flask, distil the ether and heat for a half hour in an oven. Weigh, then heat again for a half hour and check the weight.—W LEPPER *Z Analyt Chem*, 98 (1934), 164-166, through *Chimie et Industrie*, 33 (1935), 676 (W A P)

Colorimetric Analysis and p_H Determinations—Applicability of the Color and Luminescence Comparator of Rojahn-Heinrich for A discussion. Illustration.—R SEIFERT *Apoth Ztg*, 50 (1935), 590-593 (H M B)

Colorimetric Methods of Analysis—Theory and Physico-Chemical Basis of Assuming that color is numerically measurable in order that a reaction may be used it is necessary to define the colorimetric function $I = f(C)$, which gives the relationship between the color intensity I and the initial concentration C of the substance to be determined. I is really a function of numerous variables (temperature, time, concentration of reagent, operating technique) to which suitably selected values must be assigned. The methods of selecting these values are discussed and exemplified by the case of the microdetermination of reducing sugars by means of phosphomolybdic reagent. The same procedure would be suitable in all cases more particularly for the elaboration of methods for detecting toxic gases.—ISTIN *14me Congrès de Chimie Industrielle Paris* (Oct 21-27, 1934), 10 pp (A P C)

Copper—Drop Method of Detection of A few cc of solution are heated for 1-1.5 minutes

with tin and hydrochloric acid, the solution is poured off, the tin washed and boiled for 1 minute with 15 cc of 65% nitric acid, the solution diluted and 0.2 cc of saturated aqueous sodium fluoride, 0.2 Gm of zinc sulphate and 0.3 cc of saturated aqueous $(\text{NH}_4)_2\text{Hg}(\text{CNS})_4$ are added, when a lilac precipitate of $\text{ZnHg}(\text{CNS})_4$, $\text{CuHg}(\text{CNS})_4$ indicates $< 10^{-7}$ Gm copper. Cobalt, lead, iron, tin, arsenic, antimony and bismuth do not interfere.—L M KULBERG *J Appl Chem Russ*, 7 (1934), 1079, through *Squibb Abstr Bull*, 8 (1935), A-957

Cresol Soap Solution—Determination of Cresol Content of H's method previously proposed (*Apoth Ztg*, 49 (1934), 183) is not applicable to cresol soap solutions containing acids of castor oil and its derivatives since these are not separated from the phenolic constituents. The following procedure is recommended whereby the resin and fatty acids are separated by alkaline lead acetate solution. Shake a mixture of 30 Gm lead acetate solution (20%), 50 Gm sodium hydroxide and 20 Gm water with 20 Gm cresol soap solution for 1 minute. In 60 Gm of the filtered liquid in a cassia flask dissolve 20 Gm sodium nitrate, decompose this solution with 20 Gm nitric acid and then proceed by the method previously reported above. For soap solutions containing chlorcresols the method previously described is modified. Before the decomposition of the alkaline solution by hydrochloric acid, add 5 cc benzoin in order to bring about an easy separation of the heavy halogen phenols (chlorcresol and chlorxylenol) from the salt solution. After subtracting the added volume of benzoin from the volume observed the % cresol may be calculated in the usual manner.—K HANDEK *Apoth Ztg*, 50 (1935), 335 (H M B)

Crystal Precipitation by Salting Out II The items discussed are α naphthol β naphthol, resorcin, hydroquinone, pyrogallol, veronal, veronal-sodium, luminal, luminal sodium, chloramine, 1,2 5-toluyldiamine hydrochloride, *p* phenylenediamine, *p*-aminodiphenylamine, 1,2 5 diaminoanisole.—L ROSENTHALER *Mikrochemie*, 18 (1935), 50 (L L M)

Diaminoacridine—Determination of, in Euflavine The difference in basicity between diaminoacridine and diaminomethylacridine is used as the basis of the electrometric and colorimetric determinations of the former in the mixture. **Electrometric Method**—The euflavine (containing diaminoacridine and diaminomethylacridine) is dissolved in 10 cc of warm water with shaking. About 0.5–1.0 Gm of the euflavine may be used. The solution is cooled and 0.5 *N* sodium hydroxide is added. The diaminoacridine then precipitates, apparently in crystalline form or as a reddish brown oily liquid which later becomes crystalline. Three of the preparations used could be titrated electrometrically after 15 minutes, having been stirred rapidly during this time. Glass electrodes were used in an arrangement described by G Kilde (*Dansk Tidss Farm*, 9 (1935), 129). The method is accurate to about 1%. **Colorimetric Method**—0.5 to 0.7 Gm of euflavine is dissolved in 10 cc of boiling water in a 250 cc flask with careful shaking of the flask (so that the solution is not cooled too quickly), 90 cc of isopropyl alcohol and 2 cc of thymol blue solution are added and the solution titrated with 0.1 *N* sodium hydroxide to a definite color change, i.e., a murky brownish color. On account of the greenish fluorescence of euflavine solutions, the titrations must be made in strong electric light. The solution is then titrated back with 0.1 *N* hydrochloric acid 0.1 cc being added at a time until the color no longer changes. About 0.2 to 0.5 cc of hydrochloric acid is usually sufficient. If precipitation occurs on the addition of isopropyl alcohol, add 5 to 10 cc of water and dissolve the precipitate by heating on a water-bath, and after the solution has cooled add a little isopropyl alcohol since too high a concentration of water interferes with the end point.—F REIMERS *Quart J Pharm Pharmacol*, 8 (1935), 218–230 (S W G)

2,4-Dinitrophenol—Detection and Determination of Qualitative and quantitative tests were described. The sample is treated with water and 4% sodium hydroxide, filtered, the filtrate acidified with hydrochloric acid and extracted with chloroform. The chloroform is evaporated, 2 cc of 10% sulphuric acid and 0.2 Gm of powdered zinc are added to a portion of chloroform residue. After standing 10 minutes a pink color should appear. The solution is then filtered, 10 drops of 1% sodium nitrite added to the filtrate and the mixture allowed to stand in the dark for 5 minutes. Two cc of saturated beta naphthol in strong ammonia is added and after 2 minutes the mixture is extracted with ether. A pink or violet color in the ether layer should appear. **Comparisons of crystals and melting points** with authentic samples of 2,4-dinitrophenol are recommended. For quantitative determination the sample is macerated with 2% sodium hydroxide, acidified with hydrochloric acid and extracted with chloroform. The chloroform extracts are then extracted with 4% sodium hydroxide until the yellow color is removed. The alkaline solution is

made up to volume and an aliquot containing about 0.1 Gm. of dinitrophenol is made neutral with hydrochloric acid. Twenty cc. of 0.1N bromine and 5 cc. of concentrated hydrochloric acid are added to the solution in a glass stoppered bottle, the mixture shaken for 1 minute, cooled and 10 cc. of 15% potassium iodide added. After shaking, 1 cc. of chloroform is added and the mixture titrated with 0.1N sodium thiosulphate using starch indicator. Each cc. of 0.1N bromine corresponds to 0.0092 Gm. of dinitrophenol—I. S. SHUPP *J. Assoc. Official Agr. Chem.*, 18 (1935), 464 (G. S. W.)

Electric Micromuffle. A Pregl micromuffle was modified by replacing the wire gauze on the horizontal tube with an electric heater made by winding No. 18 Nichrome wire around a porcelain form. The advantages claimed are: An even heat is given over the whole surface so there is no spattering, no attention is required after turning on the current until the boat is removed, the heater may be slid off the tube and allowed to cool while the weighing is made—C. J. RODDEN *Mikrochemie*, 18 (1935), 97 (L. L. M.)

Enteric Coatings—I. Laboratory Method for the Study and Control of. A study made several years ago has been continued. The pH of gastric and intestinal juices has been determined, normal range being pH 1.6 to pH 1.8, though usually showing much greater range. There is evidence that in human small intestines reactions may vary from distinctly acid to slightly alkaline. Temperature of the gastrointestinal tract has been measured with a recording thermometer. Gastric temperatures have been found between 97.5° and 102.2° F., the upper part of the intestine between 98° and 100.1° F. Ingestion of hot or cold drinks makes quick change of temperature. Motility or emptying rate of stomach has been studied. Normally, peristaltic activity begins soon after ingestion of a meal but its advent may be retarded or inhibited. Experimental work was carried out in an apparatus in which tablets rotate in buffers covering gastric and intestinal range. Though a mechanical test cannot duplicate conditions in stomachs, the procedure is valuable in a laboratory study. Hundreds of tablets have been studied. Coating surface of tablets immersed in buffers from pH 1.2 to pH 6.4, showed little change after eight hours, those immersed in buffers beginning at pH 6.4 showed signs of attack and shriveling effect within five to fifteen minutes. In addition to requisite physical and chemical properties, and physiological inertness, a coating must resist a wide and variable acid range of the stomach and disintegrate at the acid reaction found in the small intestine. If a coating becomes decidedly alkaline before disintegration begins the tablet will probably pass through the small intestine without disintegrating—MILTON WRUBLE *J. Am. Pharm. Assoc.*, 24 (1935), 570 (Z. M. C.)

Essential Oils and Their Ethanol Solutions—Presence of Methanol and Formaldehyde in. A study of the methods which purport to or actually do permit of identifying or determining traces of methanol or formaldehyde in essential oils or in their solutions in ethanol, led to the conclusion that methods based on oxidation of methanol should be rejected. Ethanol that is absolutely free from methanol, and a large number of constituents of essential oils, when oxidized under analytical conditions, give rise to the formation of formaldehyde, the usual color reactions of formaldehyde, and especially the Schiff reaction, are not specific. Traces of methanol and formaldehyde are normal constituents of numerous essential oils, they exist from the time of distillation and the aero-oxidation which is more or less inevitable contributes to increase the methanol and formaldehyde contents. Commercial alcohols nearly always contain traces of methanol, and aero-oxidation of ethanol can give formaldehyde and possibly also methanol. Ethanol solutions of essential oils containing methyl esters undergo ethanolysis even at ordinary temperature, with liberation of methanol. Presence of traces of methanol or formaldehyde in essential oils or in their ethanol solutions cannot therefore be taken as proof of adulteration—Y. R. NAVES *Parfums France*, 13 (1935), 60-73, 91-104 (in French and English) (A. P. C.)

Essential Oils—Determination of Ethyl and Methyl Alcohols in Natural. The authors find that ethyl alcohol is present in rose blossoms from the moment of plucking, in quite remarkable proportions. They show that the Thorpe method, which is customarily used for the determination of alcohol in essential oils, gives results which are clearly deficient. They describe and give results obtained by the Thorpe method and also the Zeisel method which they suggest as possessing great advantages of sensitiveness, accuracy, speed and simplicity. In conclusion the authors state that the results given by Thorpe's method are definitely below the true quantity of alcohol present in a synthetic oil. The same is true with regard to the free alcohol present in a natural essential oil. Thorpe's method requires 12 cc. of oil, that of Zeisel does not need so much

as 1 Gm Zeisel's method is simpler and much more rapid, and is less susceptible to error than that of Thorpe—R GARNIER and I PALFRAY *Perf Ess Oil Rec*, 26 (1935), 259

(A C DeD)

Extract and Fluidextract of Coca, B P C—Assay of It is suggested that the B P C 1934 assay process given under 'Ext Cocae Liq' be modified to include the following (1) That the extraction of the alkaloids from ammoniacal solution be made by successive portions of ether until complete (2) That sufficient portion of dilute acid be used to completely extract the alkaloids (3) That the final ethereal solution be washed with a little water in order to remove any traces of ammonium salts (4) That the final residue be dehydrated with absolute alcohol (5) That volatile bases be excluded by heating the alkaloidal residue at 80° C for two hours—W A N MARKWELL *Pharm J*, 134 (1935), 416

(W B B)

Extracts—Determination of the Viscosity of Viscous The pharmacopœial descriptions of the consistency of thick extracts are held to need revision Relative or absolute values for limits of viscosity should be set A simple, inexpensive viscosimeter is described consisting of a disk which sinks through the fluid placed in a glass cylinder, the disk bearing an index shaft which slides in a millimeter-graduated, glass tube The sinking speed is determined with the stop-watch The ordinary viscosimeters are described and discussed, both the nozzle flow types such as the Ostwald pipette and the Engler the Redwood, the Saybolt and the Barbey instruments and the torsion types such as Couette's, Searle's and Hoeppler's The use of the sinking-disk viscosimeter is suggested for such extracts as *Ext absinthii*, *belladonnae*, *chamomilla filicis*, *gentianae*, *glycyrrhizae*, *hyoscyami*, *mullefolii*, *secalis cornuti* Figures are reported for various specimens of *Ext glycyrrhizae*, *gentianae* and *menyanth* For extracts made by the same general methods from the same drug a relationship of viscosity to content of dry residue can be seen and a typical curve is given The influence of temperature on the sinking speed is also shown in a typical curve Here the viscosity coefficient is about three times greater at 15° C than at 20° C hence control of the temperature during viscosimetry is of good importance—S KJELL MARK *Farm Revy*, 34 (1935), 397, 413, 425

(C S L)

Fats and Oils—Hydroxyl Number and Acetyl Value of A report of a collaborative study of three methods was made Values obtained by the André-Cook and the Roberts-Schuette methods were in good agreement Low values were reported for the West Hoaglund Curtis method likely due to a fading of the end-point in titration—W L ROBERTS *J Assoc Official Agr Chem*, 18 (1935), 435

(G S W)

Ferrous Iron—Determination of, in Presence of Organic Matter by Heisig's Method Attention is drawn to the suitability of the iodate method (Heisig's Method) for the assay of the saccharated iron compounds of the B P and B P C and of ferrous lactate It is shown that ferrous iron may be titrated with accuracy by iodate in the presence of liquid glucose, acacia traga canth, sucrose invert sugar in small amounts, levulose, dextrose, lactose, glycerin, lactic acid and citric acid Invert sugar in great excess produces a small error The method is unsatisfactory in the presence of licorice, marshmallow, gumme and aqueous extract of cochineal—G J W FERREY *Pharm J*, 134 (1935) 784

(W B B)

Glyceryl Trinitrate Tablets—Assay of Anderson's method for the assay of glyceryl trinitrate tablets is based on the volatility of glyceryl trinitrate in steam, hydrolysis with sodium hydroxide solution, reduction of the nitrate formed and distillation of the ammonia produced into standard acid The author suggests a method which is a modification of Anderson's method The suggested modification is as follows Place five tablets in a 500 cc Kjeldahl flask, add 25 cc saturated sodium sulphate solution, 75 cc water and sufficient sulphuric acid to make just acid to litmus paper (usually 0.3 cc of N/1 sulphuric acid required) Distil just to dryness, using a still head, into a flask containing 10 cc of N/10 sodium hydroxide, keeping the outlet tube below the surface of the alkali Wash down the condenser and outlet tube and evaporate the sodium hydroxide solution to dryness Add 2 cc of water, 0.3 Gm (± 0.01 Gm) of reduced iron and 2 cc of 50% v/v sulphuric acid, allow to stand for ten minutes and boil for two minutes Transfer the acid solution to a steam distillation apparatus, make alkaline with 4 cc of saturated hydroxide solution and distil the liberated ammonia into a flask containing 10 cc of N/10 sulphuric acid until the distillate measures 500 cc Take 100 cc of the distillate, add 2 cc of Nessler's reagent and compare the color produced with that produced by adding the same amounts of reagent to 100 cc of a solution containing ammonium chloride equivalent to 0.1 mg of nitrogen The color of

the unknown should not vary more than 20% from that of the standard, and a control experiment must always be carried out, the 500 cc distillate being concentrated to 100 cc. From the difference between the nitrogen content of the experimental solution and the control, the glyceryl trinitrate present can be calculated. Factor, nitrogen to glyceryl trinitrate 5.4—W. SMITH *Pharm. J.*, 134 (1935), 790 (W. B. B.)

Glyceryl Trinitrate Tablets—Assay of The method adopted by the author for the assay of glyceryl trinitrate tablets is as follows. For tablets of B. P. strength, weigh accurately the equivalent of 1 mg. of glyceryl trinitrate, in the form of powdered tablets, into a stoppered cylinder containing exactly 5 cc. of glacial acetic acid. Shake continuously for one hour, filter and transfer 1 cc. to a small porcelain dish. To this promptly add about 2 cc. of phenoldisulphonic acid, stir well and allow to stand for fifteen minutes. Dilute with about 8 cc. of water, make alkaline cautiously with ammonia and transfer to a 25 cc. stoppered vessel. When cool adjust the volume to 20 cc. and the temperature to 20° C. and filter. Compare the color in suitable glass containers with that produced as follows: (1) Dilute 1 cc. of solution of glyceryl trinitrate of exactly 1% strength with 50 cc. of glacial acetic acid, mix thoroughly, transfer 1 cc. to a porcelain dish, add phenoldisulphonic acid and proceed as above. (2) Transfer 1 cc. of a 0.225% aqueous solution of silver nitrate B. P. to a porcelain dish, evaporate gently to dryness, add phenoldisulphonic acid and proceed as above. The color produced in all three cases should be equal to 7.0 Lovibond yellow units when viewed through a glass cell of 1 inch internal width—H. O. MEEK *Pharm. J.*, 134 (1935), 791 (W. B. B.)

Gold—Microchemical Determination of, in the Presence of Palladium and Tin Large amounts of palladium and tin do not interfere with the determination of gold by a method previously reported by the author (*Mikrochemie* 13 (1933) 165 and 17 (1935), 174)—J. DONAU *Mikrochemie*, 18 (1935), 11 (L. L. M.)

Gold Sol—Preparation of, for Liquid Analysis The stock solution contains gold bromide crystals, 5.0 Gm., purified potassium bromate, 1.365 Gm., and freshly distilled water, 38.7 Gm. This solution is stable for one year. For preparation of the gold sol 1 cc. of the stock solution is first diluted with 14 cc. of distilled water and then further diluted with water to make one liter. For the reduction, 10 cc. of a 1% potassium oxalate solution is added, and the solution placed in daylight for about 20 minutes—W. HERMANN *Ztschr. Immunitätsforsch.*, 84 (1935), 279, through *Pharm. Zentralh.*, 76 (1935), 394 (E. V. S.)

Heroin—Micro-Detection of Among the various alkaloidal reagents the following give the most characteristic crystalline precipitates with heroin: (1) A saturated solution of mercuric diiodide in 10% hydrochloric acid, (2) gold chloride in concentrated hydrochloric acid and sodium picrate—WILLIAMS and FULTON *Freie Apoth. Stimmen*, 17-18 (1934), 19, through *Pharm. Tijdschr. Nederland-Indië*, 13 (1935), 56 (E. H. W.)

Indigocarmine—Use of, in Microvolumetric Analysis One gram equivalent of indigocarmine corresponds to one half gram mole $\frac{C_{16}H_{13}N_5O_5S \cdot Na_2}{2} = 233.11$ Gm. The reagent is best suited for volumetric analysis in 0.001N solution. It is standardized for use in alkaline solution against 0.01N potassium ferricyanide in the presence of sodium carbonate, for use in acid solution, against potassium permanganate in the presence of sulphuric acid. 1 cc. of 0.001N indigocarmine solution corresponds to 0.3292 mg. potassium ferricyanide. 1 cc. of 0.001N potassium permanganate solution corresponds to 0.23311 mg. indigocarmine or to 0.21111 mg. indogdisulfonic acid. Small amounts of ferrous iron may be determined with fair accuracy by oxidizing the iron with excess standard potassium permanganate, then titrating the excess permanganate with indigocarmine solution—I. M. KORENMAN *Mikrochemie* 18 (1935), 31 (L. L. M.)

Indophenol Reaction—Application of the, for the Identification of Some Organic Polyacids A drop of the neutralized acid is evaporated to dryness, mixed with a trace of phosphorus trisulphide and heated with a few drops of a solution of isatin in sulphuric acid. A blue color is developed. The reaction is most sensitive with succinic and fumaric acid but is produced also with maleic, malic, pyrotartaric, tartaric and citric acid—JOSÉ VÁZQUEZ SÁNCHEZ *Farm. Moderna*, 46 (1935), 58 (A. E. M.)

Iron—Cermetric Titration of Small Amounts of, by Means of α, α' -Dipyridyl as Indicator Dilute acid solutions of ferrous compounds give a sharp end-point (pink colorless) when titrated with ceric sulphate. The indicator solution consists of 0.25 Gm. α, α' -dipyridyl dissolved in 50 cc.

water with 50 cc of concentrated ammonia water added afterward. About 5 drops of this solution is used for 50 cc of ferrous solution. The ammonia is added to speed the formation of the colored indicator complex which develops slowly in acid solution. With this indicator, ferrous solutions containing 0.1–10 mg iron in 50 cc 1*N* hydrochloric acid may be titrated by means of 0.002–0.015*N* ceric sulphate in 1*N* sulphuric acid solution. The end point appears within one drop and is far better than with a titanous solution. Ceric sulphate solution is quite stable when guarded against direct sunlight, even in extreme dilutions. For the reduction of ferric iron, the silver reductor of Walden, Hammett and Edmonds was found to present an improvement over the Jones reductor, *et al*, provided the acid concentration is kept within 0.5–1*N* hydrochloric acid.—C. J. VAN NIEUWENBURG and H. B. BLUMENDAL. *Mikrochemie*, 18 (1935), 39.

(L. L. M.)

Lactic Acid—Determination of The author refers to the reports of Girault, who claims that the official method gives too high results, and of Bourdeau, who reports satisfactory results with the same method. The author's results indicate that the official method is a good one, but certain lactic acids yield results higher than 100% owing to the presence of esters which are hydrolyzed.—F. KAYSER. *J. pharm. chim.*, 21 (1935), 604.

(M. M. Z.)

Medicinal Mixtures—Thermo-Analysis and Eutectics of The author discusses the thermo analysis and eutectic temperatures of mixtures of several organic medicinal chemicals. Cases where a molecular combination results between the two chemicals in the mixture are discussed along with cases where no reaction occurs. Combinations of antipyrine, veramon, campral, hypnal and trigemine are fully discussed as is also the caffeine salicylic acid mixture (the sodium salicylate caffeine mixture). The following eutectic temperatures of such combinations are given:

Combination	Eutectic Temp	Composition
Bromural-pyramidon	78.0°	41 % bromural
Pyramidon acetanilid	58.5°	41 % acetanilid
Pyramidon phenacetin	78.5°	68 % pyramidon
Acetanilid phenacetin	82.5°	58 % acetanilid
Salol-benzonaphthol	34.0°	86.9 % salol
Bromural-salol	40.8°	3.5 % bromural
Bromural-phenacetin	109.0°	53 % bromural
Veronal salol	41.2°	1.5 % veronal
Veronal-phenacetin	121.6°	26.2 % veronal

The liquification of powder mixtures is discussed and tables giving eutectic temperatures and compositions of mixtures of camphor with salol, naphthaline, β -naphthol, resorcin and ethylurethan, of salol with monobromcamphor, β -naphthol, thymol, guaiacol, naphthaline antipyrine, urethan, menthol, chloral hydrate, methylacetanilid sulfonal, phenacetin and terpin hydrate, of phenol with β -naphthol, naphthaline and acetanilid, and several others are quoted from the literature.—J. MEIJER. *Pharm. Weekblad*, 72 (1935), 922.

(E. H. W.)

Mercurochrome—Determination of Mercury Content of Assuming that the B. P. C. method of assay for the mercury content of mercurochrome is accurate, and adopting the limits laid down in the particular monograph, not one manufacturer's sample examined conformed to the required standard. The results obtained by the B. P. C. method of assay show an appreciable experimental variation. The alkaline-permanganate oxidation method for the assay of mercury appears to give more reliable and consistent results than the B. P. C. method.—R. F. CORRAN and F. E. RYMLL. *Pharm. J.*, 134 (1935), 783.

(W. B. B.)

Methanol—New Method for the Determination of Small Quantities of, in Presence of Very Large Quantities of Ethanol and Its Homologues The method, which is long and delicate is essentially an accurate research method. It is based on the 4 following steps: (1) converting the primary alcohols into the corresponding iodides, (2) distillation of the alkyl halides, (3) treatment of the distillate with silver acetate to regenerate the alcohols with formation of silver iodide, which is weighed (giving the "iodization value," *P*) and finally (4) oxidizing the alcohols in the cold and determining the oxygen consumed (giving the "oxidation value," *p*). If *X* and *Y* are respectively, the amounts of methanol and ethanol to be determined, $P = 234.8 (X/32 + Y/46)$ and $p = 48X/32 + 32Y/46$, whence $X = 2 \times 32 (p/32 - P/234.8)$ and $Y = 3 \times 36 (P/234.8 -$

p/48) The method, which is described in detail, is essentially as follows. The methanol is concentrated by a suitable rectification collecting the head fraction containing all the methanol together with impurities such as acids, aldehydes, etc., the latter are removed by adding a slight excess of silver nitrate, letting stand over night, neutralizing with 10% potassium carbonate and redistilling, further rectifications are carried out if necessary, iodization is carried out at about 105° C with 3 cc of hydriodic acid (specific gravity 1.7) and 0.5 cc of sample, the vapors being washed by passing through a suspension of 10 mg calcium carbonate in 5 cc of water at 45° to 50° C and collected under a solution of 0.5 Gm silver acetate in 50 cc of water, and a current of pure carbon dioxide being passed through the apparatus, iodization requires about one hour and a quarter from the time the distillate begins to collect in the silver acetate solution, not less than 2 hours after iodization is complete the solution in the receiver is redistilled, the distillate collected under 5 cc of water and made to 50 cc, and *p* is determined in the distillate and *P* in the residue. To determine *p*, add 5 cc of distillate to 10 cc of solution containing 5 cc of 66° Be sulphuric acid and 20 mg of potassium dichromate in a 25-cc glass-stoppered Erlenmeyer, stopper, let stand over night and titrate the excess of dichromate iodometrically, under these conditions methanol is oxidized according to equation $2\text{CH}_3\text{OH} + 3\text{O}_2 = 2\text{CO}_2 + 4\text{H}_2\text{O}$, and ethanol and higher homologues according to $2\text{R CH}_2\text{OH} + 2\text{O}_2 = 2\text{RCO}_2\text{H} + 2\text{H}_2\text{O}$. To determine *P* add 1 cc of nitric acid (specific gravity 1.38) and 50 cc of water to the residue containing silver bromide, boil gently with successive additions of water to compensate for evaporation till the precipitate is a bright canary yellow, filter, wash dry 1 hour at 130° to 150° C and weigh. The limit of sensitiveness is about 0.05 mg methanol in the 0.5 cc taken for iodization, and the accuracy varies from about 0.5% for a methanol ethanol ratio of 1:100 to about 5 to 10% for a ratio of 1:1000 to 1:2,000, this, however, requires the use of very pure reagents, and commercial hydriodic acid should be purified by treatment with red phosphorus and redistillation. The various steps of the method are discussed in detail to justify the technique adopted. Application of the method to a large number of wines, brandies and fermented fruit juices showed that methanol in amounts up to over 4,000 mg per liter is a normal constituent of all natural alcoholic media — M FLANZY *Ann Fals*, 28 (1935), 260-277, cf *J Am Pharm Assoc*, *Abstract Sect*, 29 (1935), 125 (A P-C)

Methyl Alcohol—Determination of, in Alcoholic Products A method for the determination of methyl alcohol in the presence of ethyl alcohol was described. The method depends upon the formation of the iodides, their partial separation by fractionation, their conversion into salts by trimethylamine and the separation of the tetramethylammonium iodide formed from the methyl alcohol from absolute alcohol. The apparatus used is a modification of the Zeisel Fanto apparatus for the determination of methoxy groups. Red phosphorus and iodine are used rather than the more expensive hydriodic acid. Most of the interfering substances may be removed by use of a distillate of the sample — J B WILSON *J Assoc Official Agr Chem*, 18 (1935), 477 (G S W)

Microburette—New, with Removable Tip The burette designed by Khouri and manufactured by Etablissements Prolabo, 12, rue Pelée, Paris is made in two sections. The advantages claimed are easy filling and cleaning and different tips giving the size of drops desired — *J pharm chim*, 21 (1935) 607 (S W G)

Microchemical Laboratory Technique—Improvements in The items discussed are (a) some devices for working with the filter-stick of Emich, *et al*, frame, forceps and wash bottle, (b) sharpening block for glass knives, (c) an improvement in the determination of residues in the micromuffle — H K ALBER *Mikrochemie*, 18 (1935), 92 (L L M)

Microdistillation—Apparatus for The apparatus was designed for use with vacuum 0.05 cc of liquid may be distilled. No special technique is required for operation and the unit need not be constructed for each distillation. Specifications and illustrations are given — L V PEAKES, JR *Mikrochemie*, 18 (1935) 100 (L L M)

Microiodometric Determinations The investigation showed that the microiodometric determination of sulphites and tin salts by iodine may be replaced by the use of iodate. The following advantages are claimed. In the preparation of the volumetric solution no special pre-

caution need be taken to prevent loss of material through volatilization Volumetric solutions of potassium iodate do not require restandardization as frequently as do diluted solutions of iodine

Determination of Sulphite—To 2-5 cc of the diluted sulphite solution are added about 0.5 cc of sulphuric acid (1.5) and several drops of starch solution To the mixture is added 0.01N potassium iodate solution to the appearance of a weak permanent color

Determination of Stannous Chloride—To 2-5 cc of the stannous chloride solution acidified with hydrochloric or sulphuric acid, is added the starch solution and then 0.01N potassium iodate solution to the appearance of a weak blue color $2\text{KIO}_3 = 6\text{SnCl}_2$ —I. M. KORENMAN *Mikrochemie*, 17 (1935), 361

(L. L. M.)

Micropolarographic Investigations A description with illustrations is given of an apparatus by the use of which the polarographic electrolysis of quantities of solution as low as 0.005 cc is made possible The use of the apparatus and of micropipettes is discussed—V. MAJER *Mikrochemie*, 18 (1935), 74

(L. L. M.)

Microshaker Useful in Microtitrations The apparatus is made from an electromagnetic loud-speaker—K. SCHWARZ *Mikrochemie* 18 (1935), 106

(L. L. M.)

Microsublimation—Is It Useful in the Investigation of Powdered Drug Mixtures? The method employed was that of Tunmann Since little could be found in the literature, 19 drugs were first investigated individually as to sublimation products Of them, 13 were found to give characteristic results Using these drugs mixtures first of only two drugs were investigated, then mixtures of three or more components The results were tabulated Of 92 drug mixtures investigated 61 could be fully identified by microsublimation, in 25 mixtures not all of the drugs could be identified and in only 6 mixtures could none be identified—F. WIESMANN *Pharm. Acta Helv.* 10 (1935), 125

(M. F. W. D.)

Mineral Oils—Contribution to the Study of Official A comprehensive study and survey of the physical and chemical properties of mineral oils obtained from French, Belgian, German and American refineries The result of this study is a proposal of a monograph on mineral oils for the French Codex now in preparation—F. GRÉGOIRE *Bull. sci. pharmacol.* 42 (1935), 152, 217

(C. T. I.)

Mineral Pigments—Systematic Method for the Identification of II. **Blue and Green Pigments** The blue pigments were differentiated (1) By their behavior toward sodium hydroxide in the warm Prussian blue gives a red brown precipitate, other pigments remain unaffected (2) With warmed diluted hydrochloric acid, ultramarine liberates hydrogen sulphide, mineral blue (blue basic carbonate of copper) carbon dioxide, Bremen blue dissolves without evolution of gas, cobalt blue and smalt blue remain unchanged In the last two cases cobalt may be detected Cobalt blue is insoluble in boiling hydrochloric acid (1.1), whereas smalt blue is partly soluble leaving a residue of silicic acid The green pigments are warmed with diluted hydrochloric acid Mineral green dissolves with evolution of carbon dioxide, Paris green evolves vapors of acetic acid Bremen green Scheele's green and cobalt green dissolve completely without evolution of gas The last three pigments are differentiated by tests for copper for copper and arsenic and for cobalt respectively Partial solubility in diluted hydrochloric acid suggests further test for glauconite or for mixed chromium pigments Finally, if the pigment is practically insoluble in diluted hydrochloric acid it is dissolved in concentrated hydrochloric acid and tested for chromium (chromium green) In all cases special microchemical reactions are given for the elements mentioned—S. AUGUSTI *Mikrochemie* 17 (1935), 344

(L. L. M.)

Morphine—Colorimetric Assay of The method is based upon the blue color formed by morphine on reduction with silicomolybdic acid The method consists of dissolving 0.2-0.10 mg of morphine or an equivalent amount in liquid form in 5 cc of 1% hydrochloric acid, then 2 cc of silicomolybdic acid 5 cc of ammonia water (5%) and water to make 25 cc added in order given After standing for five minutes it is standardized against the standard prepared by using 5 cc of a 1/1000 solution of morphine in 1% hydrochloric acid in the given test The silicomolybdic acid is prepared according to a previous article (*Biochem. Ztschr.*, 27 (1933), 260)—R. HOFMANN and N. POPOVICI *Pharm. Zentralk.*, 76 (1935), 346

(E. V. S.)

Morphine—Determination of, in Tincture and Extract of Opium. Mannich's method (*Arch. Pharm.* 273 (1935), 112) is modified **Tincture of Opium**—Evaporate 30 Gm of the tincture in a porcelain dish on a water-bath to 10 Gm triturate with 1.5 Gm calcium hydroxide and add water to 31.5 Gm After standing for 1/2 hour with frequent stirring, filter through a plaited

filter (10 cm) To 20 Gm of the filtrate (= 20 Gm of tincture) in a 100-cc Erlenmeyer flask, add 5 Gm water, 38 Gm methyl alcohol and 7 Gm alkaline potassium ovalate solution (18.4 Gm neutral potassium ovalate, 10 Gm 0.1N potassium hydroxide, water q s 100.0 Gm) and warm on a water-bath to 50° C After cooling filter through a plated filter (8 cm), keep covered triturate 56 Gm of the filtrate (= 16 Gm of tincture) with a solution of dinitrochlorobenzene (0.6 Gm in 10 Gm) (= 12.5 cc) and then add 10 Gm water Collect the crystals which separate over night in a Gooch crucible, wash with 6 cc methyl alcohol and 4 cc ether in small portions and weigh after drying at 100° C

$$\frac{100 (\text{morphine ether} + 0.005) \times 0.632}{16} = \% \text{ morphine}$$

(Factor 0.632 is obtained by $\frac{285.2}{451.19}$ (morphine) *Extract of Opium*—Triturate 1.5 Gm of the extract with 1.5 Gm potassium hydroxide and 10 Gm water and add water to 31.5 Gm Proceed as under the assay of the tincture in which a 56 Gm aliquot is equal to 0.8 Gm of the extract

$$\frac{100 (\text{morphine ether} + 0.005) \cdot 0.632}{0.8} = \% \text{ morphine}$$

Results obtained are compared with

those by the German Pharm VI method and volumetric method—K. HANDKE *Apoth Ztg*, 50 (1935), 5101 (H. M. B.)

Morphine—Micromethod of Determination of, in Opium Preparations Mix 0.05 Gm of dried and ground opium with 0.02 Gm calcium hydroxide and add gradually 10 cc of water Mix thoroughly for 30 minutes leave standing for 15 minutes and filter through a dried filter Take 5 cc and evaporate to dryness Add 0.2 cc of an ammonium chloride solution (10%) and 3 cc of purified ether Decant the ether after 24 hours through a small filter and wash two times with 3 cc ether Finally wash the filter with 10 cc ether Dry residue and filter at moderate heat and dissolve in hot methyl alcohol, washing it through the filter, using 3, 3.2 and 2 cc Add to the filtrate one cc of 0.1N phosphoric acid and bring with water to a volume of 50 cc Ten cc are mixed with 10 cc of a saturated sodium carbonate solution and 2 cc of a solution of sodium phosphotungstic molybdate (Folin and Denis) The blue color is compared colorimetrically with a standard morphine solution containing 0.1 mg base per cc The method can be applied to opium extract tincture and morphine solutions—LUIS DE PRADO *Anales de Farm Bioquim*, 6 (1935), 12 (A. E. M.)

Nicotine—Nephelometric Determination of Small Quantities of Advantages of the nephelometric method over the author's colorimetric method are (1) smaller quantities may be used for the determination without decreasing the accuracy, (2) less time is required, (3) economy of materials, which is of particular importance in forensic investigations *Method*—Tobacco was steam distilled as described in *Bül Cultivărei și Fermentării Tutunului* 42 (1932) One hundred cc of distillate were collected, of which 25 cc were reserved for gravimetric analysis In each of 5 test-tubes was placed 5 cc of 0.5% hydrochloric acid The contents of the first tube were mixed with 5 cc of distillate, and 5 cc of the diluted distillate were transferred to the second tube Continuing in this manner, five different dilutions were prepared which differed from each other in nicotine concentration by 50% To each tube was added 1 cc of silicomolybdate reagent and the resulting turbidity was compared with that produced by a 0.0015% nicotine solution That dilution was then chosen which produced a turbidity greater than that of the standard nicotine solution An additional 100 cc of this dilution were prepared by neutralizing the required volume of distillate with 0.1N hydrochloric acid using methyl red as indicator Ten cc of 5% hydrochloric acid were added and the whole diluted to 100 cc with water From this solution different dilutions of 10 cc each were prepared with 0.5% hydrochloric acid, each dilution was mixed with 2 cc of reagent and the mixtures were compared nephelometrically

$$\% \text{ nicotine} = \frac{100,000 V f F}{V_1 V_2 E}$$

where V = cc of distillate, f = observed nephelometer reading (standard compared with test sample), V₁ = cc of diluted distillate prepared, V₂ = cc of diluted distillate used in the determination, F = titer of the standard solution in Gm, E = weight of standard—R. HOFMANN *Mikrochemie* 18 (1935) 24 (L. L. M.)

caution need be taken to prevent loss of material through volatilization Volumetric solutions of potassium iodate do not require restandardization as frequently as do diluted solutions of iodine

Determination of Sulphite—To 2-5 cc of the diluted sulphite solution are added about 0.5 cc of sulphuric acid (1.5) and several drops of starch solution To the mixture is added 0.01N potassium iodate solution to the appearance of a weak permanent color

Determination of Stannous Chloride—To 2-5 cc of the stannous chloride solution acidified with hydrochloric or sulphuric acid, is added the starch solution and then 0.01N potassium iodate solution to the appearance of a weak blue color $2\text{KIO}_3 = 6\text{SnCl}_2$ —I. M. KORENMAN *Mikrochemie*, 17 (1935), 361

(L. L. M.)

Micropolarographic Investigations A description with illustrations is given of an apparatus by the use of which the polarographic electrolysis of quantities of solution as low as 0.005 cc is made possible The use of the apparatus and of micropipettes is discussed—V. MAJER *Mikrochemie*, 18 (1935), 74

(L. L. M.)

Microshaker Useful in Microtitrations The apparatus is made from an electromagnetic loud speaker—K. SCHWARZ *Mikrochemie* 18 (1935), 106

(L. L. M.)

Microsublimation—Is It Useful in the Investigation of Powdered Drug Mixtures? The method employed was that of Tunmann Since little could be found in the literature, 19 drugs were first investigated individually as to sublimation products Of them 13 were found to give characteristic results Using these drugs mixtures first of only two drugs were investigated, then mixtures of three or more components The results were tabulated Of 92 drug mixtures investigated, 61 could be fully identified by microsublimation, in 25 mixtures not all of the drugs could be identified and in only 6 mixtures could none be identified—F. WIESMANN *Pharm. Acta Helv.*, 10 (1935), 125

(M. F. W. D.)

Mineral Oils—Contribution to the Study of Official A comprehensive study and survey of the physical and chemical properties of mineral oils obtained from French, Belgian, German and American refineries The result of this study is a proposal of a monograph on mineral oils for the French Codex now in preparation—F. GRÉGOIRE *Bull. sci. pharmacol.*, 42 (1935), 152, 217

(C. T. I.)

Mineral Pigments—Systematic Method for the Identification of II Blue and Green Pigments The blue pigments were differentiated (1) By their behavior toward sodium hydride in the warm Prussian blue gives a red brown precipitate, other pigments remain unaffected (2) With warmed diluted hydrochloric acid, ultramarine liberates hydrogen sulphide, mineral blue (blue basic carbonate of copper) carbon dioxide, Bremen blue dissolves without evolution of gas, cobalt blue and smalt blue remain unchanged In the last two cases cobalt may be detected Cobalt blue is insoluble in boiling hydrochloric acid (1.1), whereas smalt blue is partly soluble leaving a residue of silicic acid The green pigments are warmed with diluted hydrochloric acid Mineral green dissolves with evolution of carbon dioxide, Paris green evolves vapors of acetic acid, Bremen green Scheele's green and cobalt green dissolve completely without evolution of gas The last three pigments are differentiated by tests for copper for copper and arsenic and for cobalt respectively Partial solubility in diluted hydrochloric acid suggests further test for glauconite or for mixed chromium pigments Finally, if the pigment is practically insoluble in diluted hydrochloric acid it is dissolved in concentrated hydrochloric acid and tested for chromium (chromium green) In all cases special microchemical reactions are given for the elements mentioned—S. AUGUSTI *Mikrochemie* 17 (1935), 344

(L. L. M.)

Morphine—Colorimetric Assay of The method is based upon the blue color formed by morphine on reduction with silicomolybdic acid The method consists of dissolving 0.2-0.10 mg of morphine or an equivalent amount in liquid form in 5 cc of 1% hydrochloric acid then 2 cc of silicomolybdic acid 5 cc of ammonia water (5%) and water to make 25 cc added in order given After standing for five minutes it is standardized against the standard prepared by using 5 cc of a 1:1000 solution of morphine in 1% hydrochloric acid in the given test The silicomolybdic acid is prepared according to a previous article (*Biochem. Ztschr.*, 27 (1933), 260)—R. HOFMANN and N. POPOVICI *Pharm. Zentrall.*, 76 (1935), 346

(E. V. S.)

Morphine—Determination of, in Tincture and Extract of Opium Mannich's method (*Arch. Pharm.* 273 (1935), 112) is modified **Tincture of Opium**—Evaporate 30 Gm of the tincture in a porcelain dish on a water-bath to 10 Gm, triturate with 1.5 Gm calcium hydroxide and add water to 31.5 Gm After standing for 1/2 hour with frequent stirring, filter through a plated

filter (10 cm) To 20 Gm of the filtrate (= 20 Gm of tincture) in a 100-cc Erlenmeyer flask, add 5 Gm water, 38 Gm methyl alcohol and 7 Gm alkaline potassium ovalate solution (18.4 Gm neutral potassium ovalate, 10 Gm 0.1N potassium hydroxide, water $q\ s$ 100.0 Gm) and warm on a water-bath to 50° C After cooling filter through a plated filter (8 cm), keep covered, triturate 56 Gm of the filtrate (= 16 Gm of tincture) with a solution of dinitrochlorobenzene (0.6 Gm in 10 Gm) (= 12.5 cc) and then add 10 Gm water Collect the crystals which separate over night in a Gooch crucible, wash with 6 cc methyl alcohol and 4 cc ether in small portions

and weigh after drying at 100° C
$$\frac{100 (\text{morphine ether} + 0.005) \times 0.632}{16} = \% \text{ morphine}$$

(Factor 0.632 is obtained by $\frac{285.2}{451.19}$ (morphine) *Extract of Opium*—Triturate 1.5 Gm of

the extract with 1.5 Gm potassium hydroxide and 10 Gm water and add water to 31.5 Gm Proceed as under the assay of the tincture in which a 56 Gm aliquot is equal to 0.8 Gm of the extract

$$\frac{100 (\text{morphine ether} + 0.005) \times 0.632}{0.8} = \% \text{ morphine}$$
 Results obtained are compared with

those by the German Phar. VI method and volumetric method—K. HANDKE *Apoth. Ztg.*, 50 (1935), 5101 (H. M. B.)

Morphine—Micromethod of Determination of, in Opium Preparations Mix 0.05 Gm of dried and ground opium with 0.02 Gm calcium hydroxide and add gradually 10 cc of water Mix thoroughly for 30 minutes leave standing for 15 minutes and filter through a dried filter Take 5 cc and evaporate to dryness Add 0.2 cc of an ammonium chloride solution (10%) and 3 cc of purified ether Decant the ether after 24 hours through a small filter and wash two times with 3 cc ether Finally wash the filter with 10 cc ether Dry residue and filter at moderate heat and dissolve in hot methyl alcohol, washing it through the filter, using 3, 3.2 and 2 cc Add to the filtrate one cc of 0.1N phosphoric acid and bring with water to a volume of 50 cc Ten cc are mixed with 10 cc of a saturated sodium carbonate solution and 2 cc of a solution of sodium phosphotungstic molybdate (Folin and Denis) The blue color is compared colorimetrically with a standard morphine solution containing 0.1 mg base per cc The method can be applied to opium extract tincture and morphine solutions—LUTS DE PRADO *Anales de Farm. Bioquim.*, 6 (1935), 12 (A. E. M.)

Nicotine—Nephelometric Determination of Small Quantities of Advantages of the nephelometric method over the author's colorimetric method are (1) smaller quantities may be used for the determination without decreasing the accuracy, (2) less time is required, (3) economy of materials, which is of particular importance in forensic investigations *Method*—Tobacco was steam distilled as described in *Bul. Cultivărei și Fermentărei Tutunului*, 42 (1932) One hundred cc of distillate were collected of which 25 cc were reserved for gravimetric analysis In each of 5 test-tubes was placed 5 cc of 0.5% hydrochloric acid The contents of the first tube were mixed with 5 cc of distillate, and 5 cc of the diluted distillate were transferred to the second tube Continuing in this manner, five different dilutions were prepared which differed from each other in nicotine concentration by 50% To each tube was added 1 cc of silicomolybdate reagent and the resulting turbidity was compared with that produced by a 0.0015% nicotine solution That dilution was then chosen which produced a turbidity greater than that of the standard nicotine solution An additional 100 cc of this dilution were prepared by neutralizing the required volume of distillate with 0.1N hydrochloric acid using methyl red as indicator Ten cc of 5% hydrochloric acid were added and the whole diluted to 100 cc with water From this solution different dilutions of 10 cc each were prepared with 0.5% hydrochloric acid, each dilution was mixed with 2 cc of reagent and the mixtures were compared nephelometrically

$$\% \text{ nicotine} = \frac{100,000 V f F}{V_1 V_2 E}$$

where V = cc of distillate, f = observed nephelometer reading (standard compared with test sample), V_1 = cc of diluted distillate prepared, V_2 = cc of diluted distillate used in the determination, F = titer of the standard solution in Gm, E = weight of standard—R. HOFMANN *Mikrochemie*, 18 (1935), 24 (L. L. M.)

Nitrogen—Volumetric Determination of Residual, without Distillation In each of two or three small Wassermann tubes are placed 3 cc of sulphuric acid (0.1% by volume) 0.04–0.05 cc of blood (serum) are added from a capillary pipette, the pipette being washed by drawing acid into the tube two or three times. To each tube is added 1 cc of phosphomolybdic acid solution (5 Gm anhydrous sodium sulphate and 8.3 Gm phosphomolybdic acid in 200 cc of water plus 20 cc of about 5*N* sodium hydroxide, then boiled $\frac{1}{2}$ hour over a direct flame, after cooling, 10.6 cc of concentrated sulphuric acid are added and made up to 1,000 cc). After mixing, the tubes are placed for 5 minutes in a water-bath at 60° C, then cooled to room temperature and filtered through a 5 cm Schleicher and Schüll 595 filter. Three cc of filtrate are placed in a 10 cc incinerating flask together with 0.5 cc of sulphuric acid (25% by volume) and ashed over a microburner until acid vapors are no longer emitted and the residue remains colorless upon cooling. The cooled residue is diluted with a little absolutely ammonia free water, and 1 cc of indicator (15 mg methyl red, Kahlbaum, dissolved in 10 cc 1*N* sodium hydroxide and diluted to 1,000 cc with water). A solution of 27% purest sodium hydroxide is added dropwise from a capillary to the appearance of the indicator change. The neutral mixture is transferred quantitatively with a little wash water to a Hagedorn-Jensen flask containing 5 cc of hypobromite buffer mixture (a) 85.5 Gm boric acid 14.6 Gm sodium hydroxide dissolved in 800 cc water, the solution being boiled 30 minutes to expel ammonia, then diluted to 1,000 cc (b) 20 Gm of potassium bromide dissolved in 100 cc 1*N* sulphuric acid in a 1-l volumetric flask, afterward dissolving in the mixture 8 Gm bromine then diluting to the mark. To 4–5 cc of "b" is added dropwise sodium hydroxide until the brown color is changed to yellow then 10 cc of buffer solution "a" and finally enough water to make 100 cc. After the addition of several granules of iodate free potassium iodide and 3 cc of hydrochloric acid (fuming acid diluted with an equal volume of water), the mixture is titrated with 0.0025*N* sodium thiosulphate delivered from a Pregl semi microburet, using starch as indicator. 1 cc of 0.0025*N* thiosulphate corresponds to 11.66 mg nitrogen—F RAPPAPORT and R PISTNER *Mikrochemie* 18 (1935), 43 (L L M)

Oil of Hypericum—Examination of Fifteen samples of oil are examined by means of the color comparator of Rojahn-Heinrici (*Pharm Ztg*, 78 (1933), 504) and the quartz lamp. It is observed that the oil from *Hypericum perforatum* L shows a yellow red fluorescence and the capillary streaks prepared from the oil of *Hypericum verum* fluoresces red-violet under the quartz lamp—F SONNTAG *Apoth Ztg* 50 (1934), 399–401 (H M B)

Oil of Peppermint—Determination of B proposes the following procedure. Weigh the oil, acetylate and saponify as directed in the German Pharm VI then add 1 cc phenolphthalein solution and 1.5–2 cc of official methylene blue solution diluted 1:10 and titrate with 0.5*N* hydrochloric acid until the color change is red violet to green—G BAUMGARTEN *Apoth Ztg*, 50 (1935) 364 (H M B)

Oil of Peppermint—Determination of Menthone in Menthone will form a ketoxime with hydroxylamine hydrochloride which reaction releases free hydrochloric acid thus 1 molecule of menthone will liberate 1 molecule of free hydrochloric acid which may be titrated (1 cc *N*/₂ KOH is equivalent to 0.077 Gm menthone). The reagents used are a 50% solution of hydroxylamine hydrochloride in alcohol half normal alcoholic potash and methyl orange Poirer No 3 as indicator. Two–3 Gm of peppermint oil are weighed out, two drops of helianthine and 15–20 cc of the solution of hydroxylamine hydrochloride added. The liquid is colored red. Half normal alcoholic potash is then carefully added, care being taken that the solution does not become alkaline. The solution is then repeatedly shaken, after which small quantities of the hydroxylamine solution are repeatedly added until the red color disappears permanently. The solution is then carefully neutralized with the half normal alkali and the menthone content calculated from the number of cc used—GASTON PARRAUD *Bull sci pharm*, (1935) 337, through *Pharm Weekblad* 72 (1935), 878 (E H W)

Oil of Turpentine—Detection of Pine Oil in H finds that the following modification of Wolff's test (*Farbenztg*, 17, No 2) is satisfactory. Mix equal parts of a solution of 0.5 Gm calcium ferricyanide in 250 Gm water and a solution of 0.2 Gm ferric chloride in 250 Gm water and add to 8 cc of this mixture in a test-tube 5–8 drops of the oil and shake vigorously for 15 seconds. If pure pine oil is present a light blue color is noticeable in the border zone becoming quickly stronger and after 2–5 minutes strong blue color. The iron solution becomes immediately green yellow to yellow green to green to blue green and after 5 minutes blue. After 15 minutes there is a

deep dark blue turbidity in the border zone and the iron solution is deep blue and somewhat turbid, after $1\frac{1}{2}$ to 1 hour a precipitate of Berlin Blue is formed which settles to the bottom. With *Pure oil of turpentine* the border zone after shaking and after 2-3 minutes remains colorless and the lower liquid is pure yellow to yellow green (5-10 minutes) and then green (slowly), in 3-5 minutes a light blue color appears in the border zone. Old and fresh oils react alike. With pine oil additions up to 30% the test is as with pure pine oil. Additions of 10-20% may be easily recognized especially by comparison of the iron solutions, since with pure oil this solution becomes yellow green in 10 minutes and is, by only a small addition of pine oil, soon colored blue-green or blue, with 10% pine oil a green color and after 5 minutes a blue green color. The pure oils in the course of an hour or more never give more than a green color to the iron solution. Oils containing pine oil color the iron solution in this time deep blue and also become turbid. Two tables are given: (1) six oils from various sources are compared as to the color produced with potassium hydroxide and (2) the appearance of the border zone and ferric chloride solution after 1, 2, 3 and 5 minutes and 10-15 minutes with shaking with six samples of oils using the Berlin Blue test just described.—K. HÖLL, *Apoth. Ztg.*, 50 (1935), 748-750 (H. M. B.)

Opium, Concentrated, D. A. B. VI—Preparation of, in the Drug Store and Critical Evaluation of the D. A. B. VI Method of Preparation and Assay. The author discusses in great detail the preparation and evaluation of concentrated opium. The pharmacopoeial directions are reviewed and criticisms, suggestions and explanations made. The D. A. B. VI method is discussed under the following headings: I. Extraction of all the strongly basic alkaloids which are precipitated from aqueous solution by ammonia, II. Extraction of the alkaloids not precipitated by ammonia but extractable with ether, III. Extraction of the weak alkaloids precipitated by sodium acetate, IV. Extraction of the non-precipitable alkaloids by shaking out with chloroform phenol after alkalization with sodium bicarbonate, V. Conversion of the free alkaloids into hydrochlorides. Methods for the estimation of the morphine content of concentrated opium are also reviewed and compared with the official calcium method.—F. HAGELSTEIN, *Pharm. Ztg.*, 80 (1935), 544 (G. E. C.)

Peppermint Oils—Detection of Japanese Mint Oil in. In the course of an investigation with large quantities of low-boiling fractions of Japanese oil, furfuraldehyde to the extent of 0.018% was detected. This proportion was found to be sufficient to give a typical aniline acetate color reaction. When the test was applied to American oil, a slight color developed, but to a much smaller degree. The details of the test are as follows: The oil (0.1 cc), measured from a 1 cc pipette (graduated in $1/100$ th cc), is mixed in a test-tube with 5.0 cc of a 2% solution of freshly redistilled aniline in glacial acetic acid added from a burette. The reaction mixture is examined in a 1-cm. cell of a Lovibond tintometer (B. D. H. pattern) after an interval of 10 minutes. The reaction mixture must be protected from bright light. Many samples of American oils, Italian oils, French oils, English oils and Japanese oils were subjected to the tests. The results obtained are tabulated.—ANON, *Perf. Ess. Oil Rec.*, 26 (1935), 247 (A. C. DeD.)

Pepsin—Action of, Especially in Pepsin Wine. Methods of evaluation are reviewed especially that of Utim (*Biochemische Zeitsch.*, (1934), 271). Good results are also obtained by Brandrup's method (*Apoth. Ztg.*, 43 (1928), No. 97). Commercial pepsin wines were tested and it was found that they did not correspond to the standards of the German Pharmacopoeia VI or contained no pepsin at all.—H. ESCHENBRENNER, *Apoth. Ztg.*, 50 (1935), 795-797 (H. M. B.)

p_H—Conception, Value, and Measurement of. A review.—A. KUFFERATH, *Apoth. Ztg.*, 50 (1935), 348-350 (H. M. B.)

Phenylethylbarbituric Acid—Solubility of, in Ether. One gram of phenylethylbarbituric acid is soluble in 18.6 Gm. of anæsthetic ether and 20.2 Gm. of pure ether (treated with sodium). One gram of the barbiturate will dissolve in 17.4 Gm. and 15.35 Gm. of ether containing respectively, 1% and 2% alcohol.—M. ARQUER, *Bull. sci. pharmacol.*, 42 (1935), 200 (C. T. I.)

Platinum Metals—Microscopic Identification of. The microbehavior of the elements of the platinum group toward many reagents was observed. The group as a whole, with the possible exception of ruthenium and rhodium, shows a predominating tendency to form salts of definite crystalline form which are possibly, in many cases, complex compounds of the Werner type. The triad made up of osmium, iridium and platinum forms an isomorphous series as is apparent in the isomorphous crystals formed with the same reagent in many of the tests. A method for the microscopical analysis of the group was developed. In the analytical method gold

was separated from the rest of the group by extraction with ethyl acetate, and osmium by distillation of the volatile tetroxide. Both separations are rapid and are advantageous in that interferences in testing directly for the presence of the remaining elements will therefore be lessened by the absence of these two. Numerous tables giving a description of the results of the analyses are shown.—W F WHITMORE and H SCHNEIDER *Mikrochemie*, 17 (1935), 279 (L L M)

Polarization in the Apothecaries' Laboratory The application of polarization in the examination of medicaments with direct and specific action, and in urine analysis is discussed.—ENGELESLEBEN *Apoth Ztg*, 50 (1935), 538-540 (H M B)

Potassium Bromate—Note on Standard Solutions of It was found that potassium bromate may be readily purified by recrystallization. The salt is quite stable if kept in brown stoppered bottles and may be weighed directly to make a standard solution.—M L YAKOWITZ *J Assoc Official Agr Chem*, 18 (1935), 505 (G S W)

Potassium Chlorate and Sodium Chlorate—Determination of Chlorate in Most pbarna copœias utilize the method of Mohr for the determination of chlorate in potassium chlorate. This method depends upon the liberation of an equivalent quantity of iodine from potassium iodide in the presence of acid, the iodine resulting from the reaction being titrated with thiosulphate. While this method gives satisfactory results if the directions are carefully followed (strong acid must be used) the authors suggest the following method. 0.8 Gm of potassium chlorate is dissolved in 100 cc of distilled water. Ten cc of this solution is mixed with 15 cc of commercial sulphurous acid (about 6% and free from sulphuric acid and chloride). This solution is boiled for ten minutes, small quantities of distilled water being added from time to time to keep the volume constant. After the sulphur dioxide is evolved the chloride content is determined by the Volhard method using potassium thiocyanate. In this method the potassium chlorate is reduced to potassium chloride while the sulphurous acid is oxidized to sulphuric acid. The principal advantage of the method is the getting away from working with strong acids. Mixtures of chlorate and chloride may be determined by running a chloride determination first, then one after the reaction is complete and determining the chlorate by difference. The method works equally well with sodium chlorate.—A ENSINK and J J HOFMAN *Pharm Weekblad*, 72 (1935), 950 (E H W)

Pyramidon—Color Reactions of It is well known that Pyramidon—in contradistinction to antipyrine—gives a purple color with a variety of mild oxidizing agents. Wagenaar (cf *J Am Pharm Assoc, Abstract Sect*, 24 (1935), 171), has suggested potassium persulphate as particularly well adapted to this reaction. The author has comparatively studied the effect of a 5% potassium persulphate solution and a 0.1N solution of iodine as oxidants of pyramidon in solutions of various concentrations. He finds (1) that iodine is much more sensitive, one drop in 5 cc giving a perceptible purple with 0.01% of pyramidon while potassium persulphate gives no reaction with this concentration. (2) In pyramidon solutions of the same concentration the purple color appears more rapidly with iodine than with potassium persulphate. (3) The purple color obtained with iodine is much more lasting than that obtained with potassium persulphate, the color of the latter changing rather quickly to reddish brown.—N SCHOORL *Pharm Weekblad*, 72 (1935), 669 (E H W)

Quinine Iodobismuthate—New Method for the Quantitative Determination of The following method is recommended. Dissolve 1 Gm of quinine iodobismuthate accurately weighed, in 10 cc of acetone, add to the solution of 0.9 Gm of silver nitrate dissolved in 20 cc of water. Remove the acetone by heating on a water-bath, and add 50 cc of 95% alcohol. Allow the precipitate to settle completely by setting the mixture aside for several hours, then decant onto a tared Gooch crucible. Wash the precipitate with three 20 cc portions of 95% alcohol, heating each time on a water-bath and taking care that the lukewarm liquid does not carry any of the precipitate onto the filter. Combine the washings with the filtrate (1st filtrate). Remove the alcohol from the Gooch crucible by drawing through it a current of air, and remove the alcohol from the precipitate in the beaker by adding 10-15 cc of water and heating on a water bath almost to dryness. Wash the precipitate with four 10-cc portions of nitric acid (1:1) each time heating carefully, with agitation, on a water-bath, finally decant the boiling acid liquid onto a Gooch crucible and, after cooling, apply suction. After the fourth washing transfer the entire precipitate to the filter using cold water acidified with several drops of nitric acid and combine the wash water and the acid liquid (2nd filtrate). Wash the precipitate twice with alcohol and then dry

in an oven first at 100° C and then at 130° C to constant weight. The percentage of iodine may be obtained from $p' \times 54.05$, where p' equals weight of silver iodide. Evaporate the 1st filtrate to a small volume on a water bath, removing all the alcohol. Take up the warm residue with 20-25 cc of water and 4 cc of N sulphuric acid, transfer to a hard glass tube marked at 50 cc and make up to the mark with the washings from the beaker using hot water. Filter and take a polarimetric reading using a 2 dm tube. The percentage of quinine may be obtained from $-1.68^\circ 15.5 = p'' \times$, where p'' is the reading observed expressed in degrees and hundredths of a degree. Quantitatively transfer the 2nd filtrate into a 600 cc beaker, using water, then add in small portions, with continuous shaking, a cold saturated solution of ammonium carbonate until a persistent precipitate forms (the beaker should be covered with a watch glass to prevent loss), then add a slight excess of the carbonate solution, boil and then collect the precipitate on an ashless filter, washing 4 or 5 times with hot water. Dry and ignite the precipitate in a small tared crucible. The percentage of bismuth may be obtained from $p'' \times 89.7$, where p'' is the weight of Bi_2O_3 . The results obtained with the above method check those obtained by the method now in use.—LORENZO BRACALONI *J pharm chim*, 22 (1935) 49-52 (S W G)

Remedies, Nostrums and Cosmetic Agents—Results of the Examination of The tests on 47 products are reported.—C GRIEBEL *Apoth Ztg*, 50 (1935), 848-850 (H M B)

Santonin—Artemisias of Afghanistan Producing Samples of *Artemisia* species were subjected to microchemical tests to determine the presence of santonin. Five tests described are (1) A 0.5 Gm sample is extracted for 5 minutes with 5 cc of rectified boiling alcohol. To the extract a small pellet of potassium hydroxide is added and the mixture is shaken and heated cautiously. A carmine color indicates the presence of santonin. (2) A small sample of finely powdered drug is extracted with benzene and then heated over an alcohol flame to volatilize the solvent. One-2 drops of sodium methylate are added—a red orange color indicates santonin. (3) A microscopic examination for santonin crystals. (4) A 0.5 Gm sample is shaken with 5 cc of chloroform, benzene, carbon tetrachloride and alcohol respectively, for 10 minutes. Each filtrate is then evaporated to dryness. If santonin is present, a deep orange color will be produced after adding 2-3 drops of sodium methylate along the edges of the extracts. (5) Same as (4) except potassium methylate is used in place of sodium methylate. A procedure for a chemical analysis and determination of santonin in *Artemisia* is as follows. 13 Gm of coarsely powdered drug is extracted with 65 cc of water for 15 minutes on a water bath and then heated with careful stirring for 15 minutes more after adding 25 cc 4*N* hydrochloric acid. The mixture is cooled and while still tepid is poured into a separatory funnel. After complete cooling, the sample is treated with 13 Gm of tragacanth and 130 cc chloroform and shaken for 1/2 hour vigorously. This is set aside for 1/2 hour and shaken at frequent intervals. The chloroform extract (101.5 cc \equiv Gm of drug) is separated, filtered and concentrated to 5 cc. The concentrate is heated with 100 cc of 5% baryta until all chloroform has been removed and a green yellow resinous precipitate separates. After 5-10 minutes' additional heating the mixture is filtered and the precipitate washed with 100 cc warm water. The filtrate is made acid to Congo red with dilute hydrochloric acid. This solution is heated at 60-70° for several minutes and further acidified with hydrochloric acid and reheated for 10 minutes more on a water bath. The product while still warm is poured into a separatory funnel and extracted with 25.15 and 10 cc portions of chloroform. The combined extracts are distilled and the dry residue is dissolved in 7.5 Gm of absolute alcohol and 42.5 cc of 60-70° water. The solution is refluxed on a water-bath for 15 minutes and then filtered. The flask is washed with 2-5 cc portions of 15% alcohol (w/w). The cooled filtrate is refluxed with 0.08-0.09 Gm of infusorial earth for 5-10 minutes. The mixture is filtered and the residue washed with 10 cc of 15% alcohol. The filtrate is set aside for crystallization and the product after 24 hours is recrystallized from 15% alcohol and dried at 100-105°. To the weight of santonin obtained is added 0.046 Gm for solubility correction. The article includes a short history of investigation on Indian *Artemisias*.—N A QAZILBASH *Bull sci pharmacol*, 42 (1935) 129 (C T I)

Saponification Number—Determination of, in Oils Hard fat, soya bean oil, peanut oil fatty acids tallow, cotton oil palm kernel oil and coconut oil were completely saponified with potassium hydroxide in alcoholic solution after 15 minutes' boiling. Saponification of 89-99.5% and 99-100% were obtained after 5 and 10 minutes' boiling, respectively. It is therefore recommended that the boiling time of the saponification mixture in the determination of the saponifica-

tion number be 15 minutes—J HETZER *Fettchem Umschau*, 42 (1935), 87, through *Squibb Abstr Bull*, 8 (1935), A-938

Separatory Funnel A new form of separatory funnel in which a glass filter plate is molded below the stopper The apparatus is used in such cases where ether Soxhlet extractions remove fat when the ethereal solution will pass through while the filter will retain the fat—HANS BARSCH *Pharm Zentralh*, 76 (1935), 379 (E V S)

Solution of Aluminum Acetate, G P VI It is concluded that a large number of the solutions of aluminum acetate on the market have not been prepared according to the official directions, that in properly prepared solutions there is but little change to the basic acetate and gel formation is not observed, turbidities and precipitates are unavoidable, it should be dispensed as a clear colorless liquid by filtering with or without the use of a filtering agent, specific gravity decreases with age with but a slight decrease in the basic acetate content Boric acid was found in only one product The aluminum content may be determined by the method of Matthes and Schutz (*Pharm Ztg*, 43 (1928), 353) or that of Holdermann (*Pharm Ztg*, 45 (1930), 1332) Coagulation tests were also carried out Calcium was determined by the following procedure Weigh accurately 5 Gm of the acetate solution, add 1 Gm of ammonium chloride (instead of 2 Gm as directed by the Pharmacopœia) and proceed as directed in the German Phar under the

determination of aluminum Wash the aluminum hydroxide precipitate with 50 Gm of hot water 5 times by decantation Heat the united filtrates to boiling and precipitate with boiling ammonium oxalate solution in excess (50 Gm) After several hours filter off the supernatant liquid and wash the precipitate by repeated decantations with hot water containing ammonium oxalate free from chlorides, dry, and ignite to calcium oxide—A HANNER and E DICKE *Apoth Ztg*, 50 (1935), 713-715 (H M B)

Spirit of Camphor—Refracto-Densimetric Determination of By means of the illustrated chart the amount of camphor and the percentage of alcohol in the sample may be easily and ac

curately determined by carrying out a density and a refractive index determination at 20° C—E WEBER *Apoth Ztg*, 50 (1935), 642-644 (H M B)

Spirit of Ethyl Nitrite—Preparation and Testing of H points out that the directions of the German Phar for preparing this spirit are deficient for the preparation of a strong product (24+ %) Attention is called to the fact that the reducing action of the alcohol on the nitric acid takes place in the warm and that it is of advantage to use a long condenser with an adapter dipping into the alcohol and to use absolute alcohol The following determination for the minimum content is given Place 10 cc of 0.1N silver nitrate in a medicine bottle, rinsed with distilled water, and introduce 10 Gm of the spirit, 20 Gm potassium chlorate solution (5%) and 5 Gm nitric acid (25%) Close the container and allow to stand with frequent vigorous stirring for 1/4 hour In the filtrate hydrochloric acid does not produce a turbidity or precipitate This corresponds to a minimum density of 0.835 or 1.88 Gm of ethyl nitrite in 100 cc of spirit, a maximum density permitted should be 0.845 equal to 1.9 Gm of ethyl nitrite—G HAMANN *Apoth Ztg*, 50 (1935), 922-923 (H M B)

Strychnine and Quinine—Quantitative Determination of, in Mixtures The distribution ratios of strychnine and quinine between aqueous hydrochloric acid and chloroform and hydrochloric acid sodium chloride solutions and chloroform are reported and this information is applied in a study of the methods for separating these alkaloids which have been published by Evers (*Pharm J*, 109 (1922), 90), a modification by Evers and Haddock (*Quart J Pharm Pharmacol*, 4 (1931), 314) adopted by the Brit Phar, and the method of the Dan Phar, 1933 The first of these methods employs 2N hydrochloric acid, the two latter methods use 1N hydrochloric acid and saturated, aqueous sodium chloride, mixed 1:1 The distribution coefficient of strychnine between chloroform and 2N hydrochloric acid is approximately 1.0, while that of strychnine between chloroform and the acid salt mixture is about 3.2 at room temperature Using ordinary commercial chloroform no constant distribution ratios can be obtained with quinine This is shown to be due to the content of alcohol present as a stabilizer in such chloroform Using alcohol free chloroform constant values are obtained The distribution of quinine between chloroform and 2N acid is approximately 1.6×10^{-2} , while its distribution between chloroform and the acid salt mixture is about 3.4×10^{-2} This information is applied in the assay methods above cited Thus, assaying Easton tablets by the Dan Phar method, after 5 extractions of the aqueous solution of the tablets with one half volume of chloroform, about 1% of strychnine will remain in the aqueous layer In the after extraction of the chloroform extract with acid-salt solution (2 x 5 cc) about 2.6% of the strychnine enters the aqueous phase In a single extraction of this with 10 cc chloroform about 80% is reextracted, leaving 0.6% of the strychnine content of the assay specimen Thus the loss of the alkaloid in process is about 1.0% plus 0.6% or 1.6% If the process of extracting with anhydrous ether described in the Dan Phar is conducted the loss may be brought under 1% As to quinine, with the use of alcohol free chloroform in Ever's method about one third as much chloroform is held back in the chloroform layer as when using chloroform which contains alcohol Using the commercial chloroform in the Dan Phar method about 0.028 Gm of quinine base remains in the strychnine, but the ether extraction removes this Using alcohol free chloroform the amount of quinine remaining in the strychnine is lessened A little strychnine tends to be removed suspended in the wash-ether, this is collected on a filter and returned by dissolving in 10 cc chloroform Titrations in alcoholic solution using a methyl red methylene blue indicator mixture are recommended both for total alkaloid and for the strychnine assay—F HALSTROM *Dansk Tidsskr Farm*, 9 (1935), 181 (C S L)

Strychnine Salts—Micromethod for the Identification of The strychnine salts are heated with a 4% sodium glycerophosphate solution which results in a characteristic crystalline precipitate By this method small quantities of strychnine sulphate, strychnine nitrate, strychnine phosphate and strychnine glycerophosphate may be identified in mixtures with other alkaloids—v KLOBUŠIČSKÝ *Freie Apoth Stimmen* (Aug 17, 1934), 18, through *Pharm Tijdschr Nederland-Indië*, 13 (1935), 56 (E H W)

Sweet Lupines—Chemical Method for Rapid Determination of Alkaloid Content of, for Breeding Dissolve 0.8 Gm of potassium iodide and 0.4 Gm iodine and dilute to 1,000 cc with distilled water This solution gives a color reaction with alkaloids when these are present in about 0.1% concentration For further separation for solutions containing under 0.1% alkaloids, use a stronger solution made up of 1.2 Gm potassium iodide and 0.6 Gm iodine and diluted to 1,000 cc with distilled water—E KUNZ and J HOREL *Sborník Českoslov Akad Zemedelske*, 10 (1935), 95, through *Chem Abstr*, 29 (1935), 4520

Syrup of Ferrous Iodide The syrup prepared according to the official process does not always meet the requirements of the D A B When 42 parts of iodine are used in place of the 41 directed a satisfactory preparation is obtained Inability to prepare an unobjectionable syrup is attributed to failure to comply rigidly with the D A B VI directions to add the iodine very slowly with constant cooling to the iron-water mixture The following method employed by the author yields a preparation with the required iodine content The iron-water mixture is placed in a strong, glass stoppered flask which is cooled by immersion in ice water For the preparation of 250 Gm of syrup the iodine is introduced in 10-12 portions, the flask being kept tightly stoppered between additions —P HORKHEIMER *Pharm Ztg* 80 (1935), 441

(G E C)

Tartaric Acid—New Reaction of A solution containing 2 Gm of resorcin and 10 Gm of potassium bromide dissolved in 100 cc of distilled water is prepared and 1 cc of concentrated sulphuric acid is added One-tenth cc of the above reagent 2 cc of sulphuric acid and 0.1 cc of tartaric acid solution are mixed in a tube The mixture is then placed in a boiling water bath, and at the end of one minute a pale blue color appears, which becomes deepest at the end of five minutes If 1 cc of distilled water is added, the color changes to red and further dilution only changes the depth of the red color If the solution is neutralized, the color changes to violet This reaction is specific for resorcin, as other phenols do not react in this manner The reaction can be used to identify tartaric acid even in the presence of bromides, nitrites, bromates and iron compounds —MAURICE PESEZ *J pharm chim* 21 (1935) 542 (M M Z)

Tollens' Reaction—Use of, in the Analysis of Medicinal Products Tollens reaction can be applied to a large number of substances Guaiacol can be determined by it in mixtures with other substances The optimal quantity is about 0.05 Gm —R SAN MARTÍN CASAMADA *Farm Moderna*, 46 (1935) 89 (A E M)

Ultraviolet Absorption—New Apparatus for Measuring The apparatus depends upon the use of a set of 25 quartz plates 0.5 mm thick, and the comparison of the absorption by the quartz plates and the sample A table is given showing the values in wave lengths (A) and densities for the series of plates The use of the apparatus is explained in detail and an illustration is given —R FABRE and L AMY *J pharm chim*, 22 (1935), 5-15 (S W G)

Variation Statistics of Drugs—Contribution to Three tables accompany the article one showing the fixed oil content of sweet almonds, one of the fixed oil content of bitter almonds and one giving the amygdalin content of bitter almonds As a rule, the smaller cotyledons have a higher percentage of oil In the case of amygdalin content both cotyledons generally contain about the same amount of glycoside, and the percentage of amygdalin in a single cotyledon does not vary far from the average value In many cases the fatty oil content of the two cotyledons of bitter almonds varies more than the amygdalin content The average values for the oil content of the two cotyledons of both sweet and bitter almonds differ by very little —L ROSENTHALER *Scientia Pharm*, 6 (1935) 79 (M F W D)

War Gases—Detection of A discussion of the importance of detecting the presence and nature of war gases, of methods of investigation in the laboratory, of sources of error and of the practical realization of detection in actual warfare —LUCIEN LEROUX *14me Congres de Chimie Industrielle Paris* (Oct 21-27, 1934), 7 pp (A P C)

Yohimbine—Composition of Commercial The authors found that a number of commercial preparations of yohimbine consisted principally of a base which possessed the melting point and optical rotation of isoyohimbine —J P WIBAUT and A J P VAN GASTEL *Rec trav chim* (1935) 85, through *Pharm Weekblad* 72 (1935), 879 (E H W)

Zinc—Estimation of, in the Presence of Iron, Aluminum, Uranium, Beryllium and Titanium
 III About 1-7 mg of potassium zinc sulphate $K_2SO_4 \cdot ZnSO_4 \cdot 6H_2O$ (double recrystallized) corresponding to 0.15-1 mg of metallic zinc were weighed into a microbeaker and dissolved in about 1.5 cc of water The necessary amount of any of the foreign elements (Fe Al U Be and Ti) in the form of solution of one of their suitable salts was added to this solution Iron must be present in the ferric state or converted into the latter by oxidation with a few drops of bromine water 0.4-1 cc of a 5% sodium tartrate solution was then added to the zinc salt solution and ammonia vapor was blown over its surface until the latter smelt of ammonia The zinc was now precipitated by adding drop by drop, to the mixture a solution of quinaldinate (equivalent to 1 Gm quinaldinate acid per 100 cc of solution), rotating the beaker occasionally during the addi

tion of the reagent 0.2–0.25 cc of the reagent in excess of the theoretically required amount (0.2–1 cc) was added in each case. The alkaline tartrate prevents the precipitation of iron, aluminum, etc., by quinaldine acid. But as zinc quinaldinate is appreciably soluble in alkalis the excess ammonia was removed by blowing air through a capillary over the surface of the mixture at a temperature of 60° C. The microbaker was gently warmed on its stand in the water-bath. Temperatures higher than 60° C must be avoided to prevent reduction of ferric to ferrous iron which at once forms ferrous quinaldinate that precipitates along with or is absorbed by the zinc quinaldinate. As soon as the ammonia was removed, the solution was rapidly cooled, and filtered at once through Emich's asbestos packed filterstick. The zinc precipitate was washed with hot water and then dried in the Benedict-Pichler drying apparatus in a current of air at 125° C. Weighings were made in a Kuhlman's balance. The zinc precipitate contains 15.29% zinc according to the formula $Zn(C_{10}H_8NO)_2 \cdot H_2O$ —P. RAY and M. K. BOSE *Mikrochemie*, 18 (1935), 89 (L. L. M.)

Zinc—Microdetermination of, by Means of Anthranilic Acid. A comparative study of the techniques of Pregl and Emich. An excess of 0.3–0.33 cc of reagent should be used in the assay, the exact amount to be determined by a preliminary test. The use of reagent in excess of this amount affords results about 1% too high.—C. CIMERMAN and P. WENGER *Mikrochemie*, 18 (1935), 53 (L. L. M.)

TOXICOLOGICAL CHEMISTRY

Coniine and Nicotine—Microchemical Detection of. Coniine may be detected in the urine in cases of poisoning from the alkaloid by the following procedure. About 100 cc of urine, alkalized with potassium hydroxide, are extracted twice with 50 cc portions of ether. The combined ether extracts are shaken 4 times with 1 cc of 1% hydrochloric acid. The separated aqueous liquid is warmed to expel the ether, transferred to a 50 cc Erlenmeyer flask and alkalized with potassium hydroxide. A 1 cm glass tube, 10 cm in length and widened at one end to a diameter of 2 cm, is now inserted into the neck of the flask through a tight-fitting stopper. The widened end of the tube is covered with a short microscope slide on the under side of which has been placed a drop of reagent. The latter consists of a saturated solution of picrolonic acid in 20% alcohol. The Erlenmeyer flask is then placed on a hot plate at 150–160° C and the slide is weighted with a 20 Gm weight. The vapors of the alkaloid form a precipitate in the drop of reagent which is seen to possess crystalline form when viewed under the microscope. The micro melting point of coniine picrolonate thus obtained, after careful washings with water, is 192–194° C. Nicotine picrate melts at 218° C. By this method 50γ of coniine may be detected in 50 Gm of urine corresponding to a dilution of 1:1,000,000. This alkaloid may also be detected in tissues by the same method after first extracting the alkalized tissue with ether. Coniine may be identified also by the micromelting point of coniine hydrochloride sublimate, but the determination cannot be made with quantities less than 200γ. The micromelting point is 218° C. Nicotine may be identified by the use of the apparatus described. In this case the reagent consists of a saturated solution of picric acid.—R. FISCHER and W. PAULUS *Mikrochemie*, 17 (1935), 356 (L. L. M.)

Ethyl Bromide—Detection of Very Small Quantities of, in Blood and Brain Tissue. Minute quantities of ethyl bromide can be detected in small samples of blood or brain tissue by distilling and passing the distillate over a red hot quartz tube which converts the ethyl bromide into hydrogen bromide. After careful neutralization of the distillate the bromine is determined colorimetrically by treatment with chloramine and fluorescein which is converted into eosin by the bromine liberated. Experimentally the method was shown to be accurate quantitatively within 5%—FRIEDRICH L. HAHN *Compt rend* 201 (1935), 269 (G. W. H.)

PHARMACOGNOSY

VEGETABLE DRUGS

"Chih-Mu"—Anatomy of the Drug. The drug "Chih-Mu" is the dried rhizome of *Anemarrhena asphodeloides* Bunge (*Liliaceae*). This plant is a native of Northern China and was introduced into Japan between 1715 and 1735. Microscopic studies of this drug may be summarized as follows. *A. asphodeloides* belongs to the monocotyledons in spite of the fact that the vascular bundles are parallel and that there are seldom any lignified cells forming a sheath around

the vascular bundles The endodermis is generally not well defined Long, thin bundles of prismatic crystals which are surrounded by a cork-like membrane occur in the intercellular spaces The oil cells which are occasionally found in the cork layer contain volatile oil and their walls consist of pectinous substances Starch grains are found only in the tip of the rhizome The original article contains 11 figures illustrating the anatomy of this drug An explanatory key is given in the original abstract —N FUJITA and M FUJITA *J Pharm Soc of Japan*, 55 (1935), 71-72

(R E K)

Compositæ Leaves—V Pharmacognostic Study of The article consists of a table containing anatomical characteristics of the following classes of Ligulifloræ Cichorieae-Scolyminae Cichorieae Cichorinæ, Cichorieae Leontodontinæ, Cichorieae Crepidinæ The species included are Scolymus (2), Hymenonema (1), Cichorium (2), Lapsana (2), Scorzonera (1), Zacyntia (1), Rhagadiolus (2), Hypochoeris (3), Arnopogon (1), Leontodon (3), Picris (2), Tragopogon (6), Podospermum (2), Scorzonera (7), Andryala (1), Chondrilla (2), Taraxacum (3), Launaea (2), Microrhynchus (2), Sonchus (5), Lactuca (14), Picridium (1), Crepis (2), Prenanthes (3), Hieracium (8) The table includes a description of the cell wall, cuticle, epidermal cells, stomata mesophyll and epidermal hairs —W HIMMELBAUR and T KALTSCHMID *Scientia Pharm*, 6 (1935), 69

(M F W D)

Karkade There has come onto the market in comparatively recent times in Switzerland a drug under the name of karkade The drug is an annual shrub *Hibiscus Sabdariffa*, native to tropical America and cultivated in the East Indies, Java, Sumatra, Ceylon, tropical Africa and the West Indies The leaves may be used as a salad, medicinally for various conditions of inflammation, or as a coagulation medium for rubber The seeds when roasted can be used as food The calyx, which becomes fleshy when the fruit is ripe, is used in many ways for food and drinks It has gentle laxative properties The paper gives gross and microscopic description of the calyx and epicalyx and of the epidermal hairs Microphotographs accompany the description A short chemical investigation is made and indicates the presence of oxalic, malic, citric and tartaric acids which provide the taste —K LEUPIN *Pharm Acta Helv*, 10 (1935), 138

(M F W D)

Microscopic Mounts—Permanent Aqueous Specimens which must be kept in aqueous mountings may be preserved by sealing the edge of the cover slip with a melted wax made as follows Heat anhydrous wool fat with not more than 20% rosin, until the constituents are blended The mixture is firm at ordinary temperatures but becomes liquid on heating The slide and cover slip should be dry when the wax is applied, and the wax must come on top of the slip all the way around —H R SMITH *Ind Eng Chem, Anal Edit*, 7 (1935), 286 (E G V)

Myrrh from Kenya A sample from the Mandera district, a sample from the Wajin district and a 5 cwt trial consignment all met the requirements of the B P —ANON *Bull Imp Inst*, 33 (1935) 134-136

(A P C)

Sandalwoods—Structure of Some A discussion of a paper which appeared in the 'Bulletin of Miscellaneous Information' (Kew), No 4 1935, by Dr C R Metcalfe, describing the structure of the following Santalaceæ *Santalum album*, East Indian sandalwood, *S freycinetianum* Gaud, Hawaiian sandalwood, *S austro caledonicum* Vieill, New Caledonian sandalwood, *S Yasi* Seem, Fiji sandalwood, *Eucarya spicata* and *E acuminata* Sprague et Summerhayes, which yield Australian sandalwood, and *Exocarpus latifolius* R Br, also from Australia is given The author states that no reliable macroscopic characters have been found whereby it is possible to distinguish the wood of *Santalum album* from the various local sandalwoods belonging to the same genus The microscopical differences between the genera *Santalum* and *Eucarya*, do not appear to be more clearly defined than those existing between the various species within the genus *Santalum* The wood structure of all the Santalaceæ examined is remarkably similar *S album* is easy to identify on account of its taller rays, and the structure of *Eucarya spicata* cannot readily be confused with that of *S album* A table is given which shows the more important measurable characters by which the species may be distinguished A short discussion of each species is also included —ANON *Perf Ess Oil Rec*, 26 (1935), 244

(A C DeD)

Scrophularia Species—Pharmacognosy of the Roots and Rhizomes of Two The Chinese drug 'Hsuan-shen' is said to be derived from *Scrophularia Oldhami* Oliv Comparison of the fresh roots with those obtained in commerce corroborated this statement The fresh root reaches 10 cm in length, 2 cm in thickness and is somewhat spindle shaped The drug is dark or blackish

brown, dark colored within, tastes sweet at first and then rather bitter. The epidermis of the thick tubers changes into a metadermis. The outer layers contain thickened, mottled, stone cells, either singly or in clusters. The radially elongated woody portions consist of both parenchyma and scattered lignified tubules, frequently accompanied by wood fibers. There is no core at the center of the root. Starch and crystals are entirely absent, inulin occurs in the parenchyma cells. The underground portions of *S. Patriniana* Wydl. (= *S. Duplicato-Serrata* Makino) consist largely of rhizomes which have no stone cells in the outer bark and a core of parenchyma tissue at the center of the rhizome. The anatomical details as well as external appearances of the two drugs are portrayed in 13 figures.—T. MUNESADA *J. Pharm. Soc. Japan*, 54 (1934), 41-48.

Star Anise—Poisonous Species of H. finds that commercial samples of genuine star anise (*Illicium verum* Hook. fil.) contain also the fruits of the poisonous Japanese star anise (*Shikumi*, *Illicium anisatum* L., *Illicium religiosum* Sieb. and Zucc.) and that this adulterant may be detected by cooking cross sections through the columella or the fruit stalks in chloral hydrate and adding phloroglucinhydrochloric acid. In the genuine anise appear red-colored astrosclereids, these are lacking in the poisonous fruits. In this manner 20-50% admixtures may be detected.—HAHMANN *Apoth. Ztg.*, 50 (1935), 335 (H. M. B.)

Viscum Album L. A review of the history, botanical, pharmacognostical, chemical and pharmacological studies of this ancient drug.—R. KRESS *Apoth. Ztg.*, 50 (1935), 453-455 (H. M. B.)

ANIMAL DRUGS

Endocrine Glands—Microscopy of Powdered Desiccated A study has been made of the microscopy of certain powdered desiccated glands with a view of providing standards for them. An abstract of a paper presented before Section N3, American Association for the Advancement of Science, at the Minneapolis meeting, June 27, 1935, is given. The descriptive microscopical standards are given for thyroid, suprarenal, whole pituitary, anterior pituitary, posterior pituitary, ovary, ovarian residue and corpus luteum.—HEBER W. YOUNGKEN *J. Am. Pharm. Assoc.*, 24 (1935), 576 (Z. M. C.)

PHARMACY

GALENTICAL

Atropine Eye Ointments—Deterioration of, on Storage A thorough investigation of eye ointments containing atropine was made with a view to determining the effect of storage on their alkaloidal content. Results of the investigation are given in table form. Atropine Eye Ointment, B. P. C. 1923, was found to lose strength when stored in collapsible tubes, although the loss was only 4.8% compared with 16.3% in the case of the material in capsules. The rate of deterioration diminishes very considerably after about a month. Yellow Eye Ointment with Atropine, B. P. C. 1923, showed the most marked loss of atropine. The strength of the material in glycono-gelatin capsules falls more quickly than the portions stored in collapsible tubes and jars. The recorded alkaloidal deficiency is startling, the capsules losing 24.5% in twenty days and 89.5% in 189 days, the corresponding figures for the ointment stored in tubes being 15.2% and 86.4%. The deterioration of Eye Ointment of Atropine with Mercuric Oxide, B. P. 1932, is not affected by the capsule material. In the first month after manufacture the loss of atropine amounts to 20.5%, and during the full period of observation the loss was 32.8%. Iodoform and Atropine Eye Ointment, B. P. C. 1934, maintained its alkaloidal strength best, the loss after storage for 189 days being 4.2%. The mode of packing did not influence the results.—N. L. ALLPORT *Pharm. J.*, 135 (1935), 4 (W. B. B.)

Cinchona and Belladonna—Percolation of Rate of Alkaloidal Extraction and Effect of Degree of Communion It was found that moderately fine powder shows most rapid extraction of total solids, and also gives quicker extraction of alkaloids of cinchona. Also, in the case of cinchona, the inert material is extracted more rapidly than the alkaloids. After extraction of 50 cc. fractions of percolates from belladonna root it was apparent that an optimum degree of communion exists for the extraction of total solids of belladonna root, namely, a 44-85 powder.—A. W. BULL *Pharm. J.* 134 (1935), 792 (W. B. B.)

Crude Drug Extraction In a continuation of a previous work C discusses the extraction of crude drugs and states that the following factors determine the design of equipment to be used (1) rate of penetration which is a function of the porosity of the drug and the size of the particles involved This is accomplished by soaking or maceration, mixing pressure and vacuum, (2) rate of solution which is influenced by mixing, heat, vacuum and pressure (3) rate of diffusion which depends upon the structure of the cell wall temperature and pressure of the menstruum centrifugal force and pressure, (4) rate of separation is accelerated by pressure and centrifuging, pressure by means of steam or air or by presses appears to be the most efficient in accomplishing this end and (5) rate of concentration The Stokes vacuum process and the Scott process of extraction are discussed —*Drug and Cosmetic Ind*, 37 (1935) 36-38 (H M B)

Digitalis Tincture—Preparation of Relative Merits of Maceration and Percolation The full activity of digitalis leaf is readily extracted by a maceration process a period of two days with occasional shaking being as effective as the official percolation process although the latter gives a higher total solids figure As percolation can yield varying results in the hands of different workers, particularly on a small scale it is suggested that the official process should be changed to the simpler process of maceration which would facilitate the preparation of small quantities of the tincture —H BERRY and H DAVIS *Pharm J*, 135 (1935), 7 (W B B)

Dilutions—Preparation of, according to the Homeopathic Pharmacopœia The author laments the fact that the prescribed methods are not accurate for the preparation of high dilutions Preference is given to the so called one glass method for preparing high dilutions of liquids —H NEUBEBAUER *Pharm Zentralh*, 76 (1935) 405 (E V S)

Distilled Water, Sterile—Apparatus for the Preparation of Since the full significance of the *Aqua destillata sterilisata* of the Swiss Phar V is not appreciated by the pharmacists the justification for this preparation is set forth and its importance stressed Three types of small scale distilled water apparatus previously described in detail are compared from the standpoint of ease of operation and cleansing degree of efficiency, quality of the product based on the Swiss Phar V requirements and economy of operation It is shown that the Kontadest-Apparatus (Buch: *Schweiz Apoth-Ztg* 72 (1934) 61) yields a distilled water meeting the pharmacopœial requirements at the lowest cost per liter —BÜCHLI *Schweiz Apoth-Ztg* 73 (1935), 397, 417 (M F W D)

Dried Extracts of the New Swiss Pharmacopœia—Hygroscopicity of The new pharmacopœia has substituted dry extracts for the classical soft extracts to a greater degree than before The following is the degree of hygroscopicity of the dry extracts as given by the pharmacopœia only slightly hygroscopic extract of aloes, somewhat hygroscopic extracts of opium, cinchona, *Rhamnus purshiana* hyoscyamus, *Rhamnus cathartica* and valerian, hygroscopic, extracts of belladonna, digitalis gentian rhubarb, strychnine cola, ipecac ergot and oxgall Since the purpose of the paper is to show the result of exposure of the extracts to the air under conditions prevailing in the pharmacy the only factors taken into account were those of time of exposure and moisture absorbed The sample of extract was transferred to a tared bottle and weighed accurately The bottle was then opened for one minute, closed and reweighed The process was repeated leaving the bottle open for periods of 3 to 10 minutes in the author's pharmacy A similar series was carried out in a laboratory very close to the seashore, the bottle being opened for periods of 2, 5, 15 and 60 minutes and lastly for 24 hours The results were tabulated The amounts of moisture found to be absorbed do not correspond so well to the terms applied by the pharmacopœia Of practical importance to the pharmacist is the fact that the absorption of moisture during the first minute is quite rapid for extracts of digitalis and opium Another point of interest is that all the extracts continue to absorb moisture for a long time so that a preparation will be cut down in potency by dilution and probable alteration as a result of moisture —C BÉGUIN *Pharm Acta Helv* 10 (1935) 131 (M F W D)

Drug Extraction III Function of Preliminary Maceration in Relation to the Percolation of Belladonna Root A historical review shows by tabulation the changes made by the U S P since 1840 Various suggestions made by investigators since 1833 are briefly reviewed Comparative percolations were carried out using the U S P process somewhat modified and with varying amounts of liquid used for moistening Tables show the amount of alkaloid obtained amount of extractive and per cent of total alkaloid Rate of extraction was found to be equally rapid whether moistened with 25 cc or not Increase in moistening liquid reduced yield in first

percolate but in all cases it was all contained in the first 280 cc of percolate. Another experiment varied the time. Again, alkaloid, total extraction and per cent of alkaloid are shown and results indicate that maceration before or after packing is of no appreciable value in promoting rapid extraction. Preliminary maceration was varied and results indicate no particular advantage. In discussing results the author compares them with the findings of other investigators. In the case of powdered drugs that swell only slightly in the menstruum used, apparently the preliminary maceration serves no useful purpose. As to quantity of liquid used, similar results have been found with other drugs. Previous workers have not explained why increase in liquid decreases rate of extraction. Several factors seem to have a bearing. When no liquid is used all of the reserve percolate must have traversed the entire column of drug. When moistened before packing most of the first percolate has not traversed the entire column of drug. With 90 cc of moistening liquid and 80 cc of reserve percolate, more than 10 cc of the moistening liquid remains and it has traversed the greatest distance. With 25 cc of moistening liquid, extraction was as good as when the drug was packed dry indicating that small quantities may become rather fully saturated. When more liquid is used than can become saturated, the reserve is less concentrated. Maceration after liquid begins to drop is of little benefit in percolation of belladonna, casting doubt on the wisdom of the 48 hour maceration period of U S P X for fluid extracts. Saving of time is important. Perhaps the U S Pharmacopoeial Revision Committee might introduce a type process for percolation without maceration either before or after packing. The process could be specified for drugs that can be extracted as well without as with maceration.—WILLIAM J HUSA and S B YATES *J Am Pharm Assoc*, 24 (1935) 538 (Z M C)

Drug Extraction IV Effect of Variation in Solvents on the Extraction of Jalap Jalap was selected as a typical resin-containing drug and the effect of solvents studied in relation to swelling, penetration, inhibition and extraction. Thin strips of jalap tissue were measured before and after addition of solvents. Swelling equilibrium was attained during the first minute in water but not for 40 or more minutes in alcohol. Testing penetration on blocks, it was found to be rapid during the first hour. Between three and nine hours there was a sharp drop in weight probably due to loss of soluble constituents, followed by an increase. Swelling of blocks in water reached a maximum of 31% in nine hours. Alcohol caused little swelling and glycerin caused slight shrinkage. Extraction of resin was as complete in 15 minutes as in 24 hours but total extraction increased with time. Alcohol 4 volumes, water one volume extracted less resin than more alcoholic mixtures. Alcohol of U S P strength and absolute alcohol seem to be best solvents for extraction of jalap resin, with more water more inert extractive is obtained.—WILLIAM J HUSA and PAUL FEHDER *J Am Pharm Assoc*, 24 (1935), 619 (Z M C)

Emulsions Experiments described in this paper indicate that as a general rule, the homogenization of an emulsion containing more than 74% by volume of disperse phase leads to a partial breakdown, and accordingly emulsions which are to receive this treatment should not contain a larger percentage of disperse phase than 74. On the other hand if the emulsion is prepared by agitation alone then the percentage of disperse phase should be at least 74 by volume otherwise it is very probable that creaming would occur. Very stable non creaming emulsions are possible if the continuous phase can be induced to set to a jelly-like form by the addition of a substance such as gelatin.—J B PARKE *Pharm J*, 135 (1935) 8 (W B B)

Emulsions—Pharmaceutical An extensive review of the theories of emulsion formation is offered. Three series of experiments were conducted (1) Cod liver oil emulsion of the German Phar VI in which the proportions of gum, tragacanth, lime, calcium hypophosphite and benzaldehyde remain unchanged and the cod liver oil (200–300 parts) cinnamon water (255–383 parts) and glycerin (38–57 parts) were altered, these varied emulsions were prepared according to the pharmacopoeial directions and after five hours were pressed twice through a small hand homogenizer and again in 18 hours, they were then observed at the end of 8 and 14 days and 7 weeks. Those containing more than 250 parts of oil, 320 parts of cinnamon water and 47 parts of glycerin separated after 7 weeks. (2) Cod liver oil emulsions were made according to the following directions. Allow all of the tragacanth, which should be of the best quality to swell with 200 Gm water in a wide-necked flask for 2 days at room temperature (15–20° C) then pour through a single layer of gauze rub all portions remaining behind in a mortar with some water, pour through the gauze wash with water and add to the freshly prepared gum mucilage. Dissolve the hypophosphite in 150 Gm water mix in a large flask with the lime water and the gum-tragacanth mixture bring

to 590 Gm with water and shake for $1\frac{1}{2}$ hour In 50 Gm of the cod liver oil, dissolve the vanillin by gentle warming on a water-bath to 40°C , add peppermint oil and benzaldehyde and shake with the previous mixture Add the remainder of the oil in six portions with shaking After standing for 3 hours add nupagin dissolved in a mixture of alcohol and tinctures, and mix vigorously Ten emulsions were prepared with oil varying in amounts from 200-300 parts, lime water 25-38, salts 4.5-6.7, water 255-395, aromatic nupagin 6.0-9.0 These were treated after 5 and 18 hours as under (1) In every case an emulsion was prepared which settled but slightly after six weeks (3) Saponin, tylose (6-7 Gm tylose S 400 to 300-350 Gm water) and pectin emulsions were also studied —W KERN, A BÜCHNER, W LEOPOLD and H MOMSEN *Apoth Ztg*, 50 (1935), 691-697 (H M B)

Ergot—Effect of Hot Solvents on Note on Effect of Storage on Activity of Ergot. The effect of hot solvents on original ergot has been investigated Ether, dichlorethylene, trichlorethylene and benzene extract the major portion of the alkaloids, light petroleum does not extract the alkaloids In the case of dichlorethylene and benzene, quantitative recovery of the alkaloids has been made, proving that the alkaloids are extracted and not destroyed by the solvents *Ergota Preparata* has been found to retain its alkaloidal strength over a period of eighteen months —R F CORRAN and F E RYMILL *Pharm J*, 134 (1935), 782 (W B B)

Extract of Belladonna—Preparation of Dry The following directions are offered for the preparation of this extract (1) *By Maceration* —Extract 500 Gm of the leaves with 4,000 Gm of diluted alcohol, express (yield about 3,800 Gm), evaporate the liquid extract to 1,200 Gm, add 1,200 Gm water to precipitate the chlorophyll, evaporate 5,000 Gm of the extract in a vacuum and dilute the dry extract if necessary by dextrin Yield of alkaloids by this method is not very great (2) *By Percolation* —Moisten 500 Gm of coarsely powdered leaves with 200 Gm diluted alcohol, percolate with diluted alcohol (as directed in the Swiss Phar) (800 cc) and 1,000 Gm water, collecting 1,000 Gm of percolate, evaporate in a vacuum to 300 Gm and add 300 Gm of water to precipitate the chlorophyll and proceed as in (1) —W BRANDRUP *Apoth Ztg* 50 (1935), 921-922 (H M B)

Extract of Ipecac—Preparation of Aqueous A comprehensive review of the work performed shows that the alkaloidal content of the finished preparation depends upon the following factors degree of fineness of the drug, the concentration of the infusion and the use of an acid to aid in the extraction of the alkaloids The acids used are either hydrochloric or citric acids The results and findings of the various authors are tabulated in fifteen tables —F GSTIRNER *Pharm Zentralh*, 76 (1935), 421, 437 (E V S)

Fluidextract of Ergot. Fluidextract of *Secalis cornuti* is a pharmacopœial product frequently employed therapeutically Of the various methods employed in the preparation of this fluidextract the least logical is that given in the Russian Phar The most rational method of preparation of this fluidextract is that given by the American Phar, since this method gives a maximal extraction of the alkaloids One of the favorable factors of stability of alkaloids and fluid extracts is a proper concentration of the hydrogen ions, a medium of a p_{H} of 3-4 is most satisfactory The fluidextract must be kept at a temperature of $15-20^{\circ}\text{C}$ in one ounce bottles, of a brown color, tightly covered with oiled paper to prevent the entrance of air When the stopper is removed for a sufficient length of time the alkaloid content is rapidly decreased The fluidextract loses 50-60% of its alkaloids after having been kept under the usual conditions of a drug store over 6 months Fluidextracts are unstable products under usual conditions —G Y TROPP *Soviet Pharm*, 3 (1935), 23 (A S)

Gauze Containing Yatren—Sterilization of This type of gauze may be sterilized in an autoclave at 120°C for 15 minutes Laboratory tests show that Yatren when heated to 130°C for a long time shows no appreciable change, at 135°C sintering begins with no sharp melting point, at 140°C an orange to gray-yellow color appears, at 170°C the preparation becomes darker changing gradually at 200°C to a dark gray-brown color with no splitting off of iodine The following method is offered for the determination of the Yatren content Boil 2-3 Gm of gauze with 100 cc water and 10 cc of normal alkali filter and boil twice with water Add sufficient 1% potassium permanganate so that an excess remains after 15 minutes' boiling The excess is then reduced by some drops of alcohol Pour the cooled liquid into a 250 cc graduated flask, make to mark and filter through a double filter discarding the first portions of the filtrate Acidify 200 cc of the clear filtrate with dilute sulphuric acid add 10 cc potassium iodide solution and tit

trate the iodine with 0.1N sodium thiosulphate $1 \text{ cc } 0.1N \text{ Na}_2\text{S}_2\text{O}_3 = \frac{0.0127}{6} \text{ Gm iodine} -$

Muntsch Apoth Ztg, 50 (1935), 574-575

(H M B)

Glass—Color of, Used to Protect from Light Various types and colors of colored glass containers are tested by filling with a potassium iodide solution acidified with sulphuric acid which is then exposed one-half hour to ultraviolet light from a quartz lamp or one hour to direct sunlight, and the freed iodine is titrated. The results are tabulated. The red and brown glasses protect the solution best.—A JERMSTAD and O OSTBY *Arch Pharm og Chem*, 42 (1935), 463

(C S L)

Glycols—Some Properties of, with Special Reference to the Use of Propylene Glycol as a Solvent in Pharmaceutical Preparations The glycols, as a class of solvents, have developed rapidly during the last few years, but for pharmaceutical purposes have been almost completely ignored. The reason for this is due to the probable high toxicity of these compounds. It has been shown that diethylene glycol is definitely toxic and ethylene glycol very probably gives rise in the human body to diethylene glycol. Propylene glycol is less toxic than ethylene glycol, is probably innocuous and was therefore chosen for experiments demonstrating the following suitability of propylene glycol in other solvents, solubility of alkaloids, solubility of inorganic substances. Some dyes (Bordeaux B, brilliant green, methylene blue, orange G, tartrazine, trypan blue) were found to be reasonably soluble. Simple syrup and a number of concentrated solutions for syrups were miscible in all proportions. Arachis, linseed, olive and persic oils were immiscible, castor oil, especially at very high temperatures, was partly miscible. Volatile oils and some tinctures were partly immiscible in varying degrees, depending on the oil.—C L M BROWN *Pharm J*, 134 (1935), 794

(W B B)

Homeopathic Pharmacy—Regarding the Progress of A review which includes a comparative discussion of some of the methods employed. The original references are given.—W PEYER *Pharm Zentralh*, 76 (1935), 407

(E V S)

Hydrogen Peroxide Solution—Stability of Experiments show that the distilled water used in making the dilute solution of hydrogen peroxide should not be prepared in metallic apparatus. Hydrogen peroxide solutions prepared with such distilled water deteriorate rapidly. The distilled water required in the preparation should be made by use of glass apparatus. The kind of glass used in preserving the solution has very little influence on the stability.—P HORKHEIMER *Pharm Ztg*, 80 (1935), 507

(G E C)

Solutions—Sterile, Preparation of II A complete investigation of the Tyndallization process for preparing sterile solutions has been made and the results show that the principles underlying the process are seriously at fault. It is suggested that the Tyndallization process be considerably modified if it is to be retained as an official process. The germicidal action of some common medicaments on *S aureus* has been investigated and it is evident that many medicaments used in the preparation of solutions for parenteral injections possess some germicidal activity at atmospheric temperatures. An investigation of the effect of some common preservatives on *S aureus* has been made. Merthiolate is shown to be the most powerful germicide, a solution 1-100,000 being sufficient to kill the organism within thirty minutes.—H DAVIS *Pharm J*, 134 (1935), 788

(W B B)

Sterilization—Remarks on the Swiss Phar V Chapter on The Swiss Phar V specifies under the various solutions for injection the method of sterilizing the filled ampuls. However, while requiring the ampuls to be sterile before filling, it does not specify the method. No sterilization is required for ampuls of adrenaline hydrochloride solution.—J B L *Schweiz Apoth Ztg*, 73 (1935), 474

(M F W D)

Sterilization in the Swiss Phar V—Note on an Article on The article is comment upon one appearing earlier in the journal and points out a misinterpretation of the pharmacopoeial directions. The Swiss Phar V makes a provision for the sterilization of porcelain and glass apparatus in general, under which ampuls are expected to fall. The neglect to specify sterilization for ampuls of solution of adrenaline hydrochloride is not important, since the solution is directed to be prepared under aseptic conditions and, as has been proven, is sterile.—J THOMANN *Schweiz Apoth Ztg*, 73 (1935), 534

(M F W D)

Sterilization Methods in Pharmaceutical Instruction and Operations—Physiological-Chemical Investigations and A review of sterilization methods of the Swiss Phar, the work of

Konrich with regard to killing of organisms with heat under pressure, that of Eschenbrenner concerning the use of the esters of *p* hydroxybenzoic acid ultrafiltration and Katadyn methods. A table gives the most satisfactory of the Swiss methods for the sterilization of 64 substances and their preparations—W KERN *Apoth Ztg*, 50 (1935), 916-921 (H M B)

Tablet Granules—Method for the Preparation of A granulation technique is described which is stated to yield superior granules for tableting. This depends on shaking rather than pressing the dampened clumps through a coarse sieve. Working directions for the preparation of *Tablette Bromisoval* are cited as an example. The method is described in greater detail in *Farm Tidende*, 45 (1935), 201. The mean error of distribution of the active principle in a batch of tablets is found to be less than that of tablets made by the press granulation method—K NIELSEN *Dansk Tidsskr Farm*, 9 (1935), 174 (C S L)

Tablets—Hints and Formulæ for Making, on a Small Scale The chief troubles experienced in the preparation of compressed tablets are 'capping,' 'sticking' and 'picking.' Capping is the term applied when the upper surface of the tablet splits off. The cause is usually that of excess powder in the granulation and may sometimes necessitate regranulation. Picking is the adherence of granules to the face of the punch and occurs from a granulation which is not quite dry, or from a scratched punch. The top punch is more usually affected, and the face should be smoothed with a portion of well-used, fine emery cloth and a trace of oil. Sticking is the effect produced when the bottom punch binds in the die, and may be caused by a slightly damp granulation or excess of powder. This sometimes is caused by substances such as calcium lactate, and may be overcome by using 4% of talc as a lubricant and placing one or two drops of liquid paraffin in the die, working the machine for a minute and removing excess of grease before compression. The degree of depression will vary with different types of tablets. Tablets such as potassium chlorate, soda-mint and formamin which are required to be dissolved in the mouth are usually compressed as hard as possible. Precautions must be taken with granulations of deliquescent or hygroscopic ingredients, such as thyroid, and there should be no delay between drying and compression. In regard to shape and size of the tablet, the thickness should be at least $\frac{1}{2}$ of the diameter. Formulæ are given for the manufacturing of the following tablets: aspirin, phenacetin and caffeine saccharin, soda-mint, calcium lactate and aloes, nux vomica and belladonna—H DAVIS and F H GILLET *Australasian J Pharm*, 16 (1935) 380 (T G W)

Tinctures of B P C 1934—Alcohol Content and Specific Gravities of In the B P C 1934, limits are given for the alcoholic content of tinctures. As these limits may be used as legal standards it is desirable that they should be in accordance with samples prepared on a manufacturing scale. Figures which are recorded in a table show that the alcoholic content of the majority of the tinctures is well within the limits allowed by the B P C, and in most cases approaches the higher limit. Specific gravities of these tinctures are also recorded in the table—C T BENNETT and F C L BATEMAN *Pharm J* 135 (1935) 796 (W B B)

Wax-Paraffin Ampuls—Use of, for Silver Nitrate Solution Used in Prevention of Ophthalmia Neomatorum The ampul is lined with paraffin by dipping the spindles in a mixture containing 71% beeswax, 8% paraffin oil and 21% of a 56° C melting point paraffin. Silver nitrate in this paraffin lined ampul will probably retain the characteristics of a fresh solution in the new ampuls for from 10 to 12 times as long at the relatively high temperature of 37.5° C as does the silver nitrate solution in the old type of ampul and will be distributed with an expiration date of 1 year, instead of the present 6 months' dating—W E BUNNEY *Am J Pub Health*, 25 (1935), 813 (A H B)

Zephriol-Bayer—Use of, in Pharmaceutical Practice Zephriol is an aqueous solution of a mixed high molecular alkyl dimethylbenzyl ammonium chloride. Several investigations were carried out to determine the usefulness of Zephriol pharmaceutically. Immersion in a 1% aqueous solution sterilized spore-free apparatus such as filter plates, etc., on standing with them for one hour, however, longer periods of immersion rendered the filter plate hard and brittle. More concentrated solutions produce this result more rapidly. Spore bearing material resisted a 1% solution at room temperature but on heating to 100° C for 30 minutes was rendered sterile. Immersion for 15 to 30 minutes in a 10% solution of Zephriol containing 1% of soda to prevent rusting, was sufficient to sterilize surgical instruments. The 10% solution had a greater sterilizing capacity than Sapro formaldehydratus of the Swiss Phar V—J THOMANN *Pharm Acta Helv*, 10 (1935) 117 (M F W D)

PHARMACOPŒIAS AND FORMULARIES

Codex and Public Pharmacy The public pharmacist may rightly claim some credit for the acceptance of the Codex as an authoritative work of reference, for he was one of the first to adopt the Codex standards in contracts for unofficial preparations. In the formulary section the use of 'g' for gram is a serious mistake, and the pharmacopœial recommendation of 'G' received a warm welcome from all pharmacists who have to dispense in both systems of weights. The emulsion of petrolatum and agar is a good example of a vicious circle. The medical man who accepts the Codex as a standard wants to prescribe it because it is in the Codex, while the Codex apparently includes it because doctors ask for a formula combining the effects of agar and paraffin.—W A KNIGHT *Pharm J* 134 (1935) 88 (W B B)

Dutch Pharmacopœias This splendid article is of considerable historical interest. The national pharmacopœias of the world are listed in chronological order as to their appearance and dates of the latest edition of each are given. The history of the various Dutch pharmacopœias is then discussed. The first official pharmacopœia to appear in Holland was the Pharmacopœia Amstelodamensis appearing in Amsterdam in 1636. Other important municipal pharmacopœias are Pharmacopœia Leidensis 1638, Pharmacopœia Ultrajectina 1656, Pharmacopœia Hagensis 1659, Pharmacopœia Leovardiensis 1687, Pharmacopœia Harlemensis 1693, Pharmacopœia Dordracena 1709, Pharmacopœia Rotterodamensis 1709, Pharmacopœia Almeriana 1723 and Pharmacopœia Groningana 1729. Many of the formulas appearing in the old Dutch pharmacopœias are discussed both comparatively and in connection with the period at which they appeared. The article concludes with a table of 114 pharmacopœias published in Holland between the Amsterdam Pharmacopœia of 1636 and the Pharmacopœia Batava of 1805.—W F DAEMS *Pharm Weekblad*, 72 (1935) 1078 (E H W)

Liver Extracts The proposed U S P monograph on liver extracts, Circular 465 U S P Revision Committee, was considered and the unanimous opinion arrived at that liver extract should not be included in U S P XI until such time as a satisfactory animal or chemical assay is available.—Subcommittee on Digestive Ferments and Glandular Products.—Am Drug Manufacturers Assoc, Proceedings (1935) 197, through *Squibb Abstract Bull*, 8 (1935), A-1376

Swiss Pharmacopœia—Remarks on the New The author makes some comments on various preparations and tests of the Swiss Phar V. The points commented upon are: the definition of unsaponifiable matter; purity test for salicylic acid; identity test for tartaric acid; identity test under agar; test under solution of aluminum aceto tartaric acid; identity reaction of antipyrine; lack of assay for orange flower water; identity test for codeine phosphate; identity test under compression of iodine; assay of solution of formaldehyde; identity test for mercuric oxycyanide; requirements under white precipitate of mercury; the title of solution of potassium arsenite; detection of benzonaphthol and the assay of rhubarb.—L ROSENTHALER *Schweiz Apoth Ztg*, 73 (1935), 469 (M F W D)

Surgical Dressings—Criticisms of Some Codex Standards for In the new Codex general instruction regarding sterilization has been included under unmedicated gauze (and under the ribbon gauze) for some reason and not in the other monographs. This instruction could well be dispensed with, as most dressings can be sterilized by the same means. Similarly the sentence 'Aseptic absorbent gauze is absorbent gauze in a sterile condition' is a curious inclusion, the exact purpose of which is not clear. If the monograph is intended to describe sterile in addition to the ordinary gauze the phrasing requires separation as formerly. A fuller description of a container which could maintain the sterile condition would be illuminating. Euflavine mercuric chloride and carbolic gauzes are worthy of corresponding definite assay processes and standards in common with the other medicated dressings. Some attempt has been made to describe the *Sterilization of Dressings* in a very sketchy manner. The article also briefly comments on the following topics: *Battista Cellulosum Ligni Charta Oleata, Corchorus, Emplastra, Gossypia, Jacoetum Lana, Ligamenta Linthea, Stupæ, Tela*.—J BAIN *Pharm J* 134 (1935) 87 (W B B)

NON OFFICIAL FORMULÆ

Adepdalen (A Erdmann, Berlin-Schöneberg) is a scouring and degreasing agent prepared from urea borate sodium sulphate magnesium sulphate and other corrigents.—*Pharm Zentralh*, 76 (1935) 553 (E V S)

Brushless Shaving Creams A good cream of this type must (1) spread easily (2) soften the beard, (3) remain soft on the skin and in the tube, (4) promote sliding of the razor on the skin (5) be removed easily by water from the razor and the face (6) not irritate the skin and (7) be pleasantly perfumed. Essentially these products are modified day creams of the oil in water types of emulsions and small amounts of superfatty bodies. Stearate creams are preferred in which stearin is saponified by potassium hydroxide, potash ammonia or triethanolamine or their mixtures up to 20-40%. Less than 14% stearin produces a cream without body, over 20% one with too much body. The purposes of the various ingredients are discussed. The following formulas are offered: (1) Cefatin 20% stearin 5% glycerin 5% water 70 parts, liquid petrolatum 1 part. For strong beards the addition of 0.5% triethanolamine worked in while hot is suggested. (2) Stearic acid 17% glycerin 10% potassium hydroxide (or potassium hydroxide solution 50° B 2%) mineral oil 2.5% water 69.5%. The quality of the product may be varied by the addition of traces or small amounts of lanolin, cocoa-butter, magnesium stearate, zinc stearate, zinc oxide, talc, colloid kaolin suspension. (3) (an American product) stearic acid 20% cetyl alcohol 1.1% mineral oil 2% ethylene glycol (or preferably diglycol, triglycol or carbitol) 1.5% triethanolamine 1.65% borax 1.85% water 71.4% perfume 0.5%. Melt the fats and add with stirring to the boiling mixture of other ingredients. After cooling to 40° C add the glycol and the perfume. (4) stearic acid 20% glycerin 5% white mineral oil 5% ammonia (26%) 2.2% zinc oxide 1.5% phenol 0.05% perfume 0.75% and remainder water.—JOSEF AUGUSTIN *Reichstoff Ind Kosmetik*, 10 (1935) 116-118 (H M B)

Burns—Preparations for (1) Picric acid 1%, boric acid 2% lanolin, absorption base 34%, cetyl alcohol 3% spermaceti 2% water 58%. Dissolve the acids in water, melt the other ingredients at 40° C. Heat the water solution to this temperature and carefully mix in small amounts. (2) Tannic acid 4.8% lanolin hydrous 27%, thymol 0.2% cod liver oil 20% short fibre soft amber petrolatum 47% eucalyptus oil 1%. Dissolve the thymol in the eucalyptus oil, add a small amount of the cod liver oil and rub up the acid in this mixture. Melt the lanolin and petrolatum and mix until it thickens, then stir in the remainder of the cod liver oil and finally the thymol solution. (3) Tannic acid 5% oil of cade 5% cod liver oil 15% lanolin absorption base 40% water 34.8% phenol 0.2%. Dissolve the acid in water and warm to 45° C. Warm the base to 40° C, add phenol and the oils. Slowly stir in the tannic acid solution. (4) Linseed oil, refined 45%, cottonseed oil refined 42% cod liver oil 10% phenol 1% camphor 2%. Mix the last three ingredients together and add to a mixture of the first two. (5) *An emulsified lotion*: lecithin 1% cetyl alcohol 2% cholesterol 1% triethanolamine stearate 7% methyl para hydroxybenzoate 0.5% mineral oil 18.5% water 70%. Heat the oil and melt in the lecithin, cetyl alcohol and cholesterol. Put the stearate in water and heat with stirring until melted, pour in the oil solution slowly and stir constantly for an hour. (6) Tannic acid 5% glycerin 5% water 90%. Dissolve the acid in the water and add the glycerin. (7) Picric acid 2% alcohol 10% water 88%. Dissolve the acid in the alcohol and add the solution to the water.—ANON *Drug and Cosmetic Ind.*, 37 (1935) 45-46 (H M B)

Chamomile Cosmetics Formulas for 18 preparations are offered in which the substance is used as the extract, oil, powder or water.—ANON *Drug and Cosmetic Ind.* 37 (1935) 187-190 (H M B)

Colloid Mills and Cosmetics Factors affecting the use of these mills in making creams are (1) the speed of the mill and the extent to which air bubbles are eliminated and (2) the rate at which the emulsion formed is passed through the mill. Six mills were studied and in a table various characteristics and their applicability in the manufacture of creams, emulsions, mucilages, etc. are discussed.—THORPE W. DEAKERS *Drug and Cosmetic Ind.* 37 (1935) 41-43 (H M B)

Creams—Claims for The following table is offered

Type of Product	Described as	Advertising Claims	Adapted to
1. Cleansing Cream	Liquefying Cream Cold Cream	Cleanses, penetrates, liquefies instantly mild stimulates softens refines the skin	All types of skin, especially oily skins

2	Lubricating Cream	Nourishing Cream, Tissue Cream, Tissue Builder, Skin Food, Nutrient Cream, Emollient Cream, Wrinkle Cream, Facial Cream, Massage Cream, Night Cream, Gland Cream	Nourishes, beautifies, softens, whitens restores relaxed tissues, prevents crepey throat, banishes lines, tones muscles, replaces natural oils, penetrates	Normal, dry, older and wrinkled skins
3	Foundation Cream (Vanishing Cream)	Finishing Cream, Make up Foundation	Finishes, protects from dust and wind, acts as a powder base	All but very young skins
4	Stimulating Cream	Circulation Cream, Circulation Ointment	Refines stimulates brings natural color	Oily sallow lustreless coarse and older skins
5	Eye Cream	Eye Wrinkle Cream, Eye Wrinkle Paste, Eye Tissue Cream	Prevents crow's feet wrinkles, rough wrinkles	Skins with incipient wrinkles and crow's feet thin and dry skins
6	Hand Cream		Feeds skin, makes it soft white, protects from chapping and roughness soothes penetrates dries rapidly, non sticky	Especially for dry, rough or red hands, foot massage

Primary Composition

Typical Formula

1	Water in oil emulsion, low viscosity oil low melting emulsion containing oil wax water	Beeswax 15 Petrolatum 10 Mineral Oil 54 Water 20 3 Borax 0 7	
2	Water in oil emulsion vegetable oils, cholesterol, lecithin cetyl alcohols, etc	Beeswax 15 Cetyl alcohol 5 Vegetable Oil 20 Mineral Oil 32 Cholesterol 2 Water 25 Borax 1 Preservative	
3	Oil in water emulsion, stearic acid, alkali glycerin water cetyl alcohol butyl stearate cocoa butter, oil	Stearic Acid 24 Potassium Hydroxide 1 Glycerin 5 Butyl stearate 6 Water 64	
4	Oil in water, water-in-oil emulsions with mineral or vegetable astringents	Paraffine 5 Lanolin 2 Mineral Oil 15	Cetyl alcohol 4 Alcohol 6-Water 65 Tannic acid 3
5	Extra effective lubricating cream with higher proportion vegetable oils etc	Beeswax 15 Cetyl alcohol 10 Vegetable oil 45 Cholesterol 4	Water 25 Borax 1 Preservative

6 Like foundation cream with skin softeners, also mucilages	Stearic acid	18.8	Glycerin	12
	Triethanolamine	1.8	Alcohol	6.5
	Cholesterin	2	Water	59.7
	<i>Drug and Cosmetic Ind</i> 37 (1935), 34-35 (H M B)			

Depilatory Developments An account of recent progress in the United Kingdom. The use of the product of passing hydrogen sulphide into milk of lime is recommended—HENRI LEE-CHARLTON *Am Perfumer* 30 (1935), 278-279, 310 (G W F)

Face Powder—Types of The following table is offered—see pages 329 and 330

Hormone and Vitamin Cosmetic Creams A brief discussion of the efficiency of cold creams as vehicles for the application or administration of hormones and vitamins—R M GATTEFOSSE *Parfumerie Moderne*, 29 (1935), 141-143 (A P C)

Liquid Shampoo A shampoo should cleanse the hair thoroughly but instead of leaving the hair in a dry brittle condition it should impart lustre without greasiness. This is accomplished by removing the natural oil and depositing oils from the shampoo in minute traces on the hair shafts which makes the hair soft and lustrous. These preparations are essentially solutions of potassium soap to which alcohol and glycerin are sometimes added. The soap is made by the cold or hot method with preference to the former. A typical soap formula is given: Coconut oil 15%, palm oil 5, caustic potash (90%) 3, caustic soda (90%) 1, alcohol 7, water 69. Dissolve the alkalis in $\frac{1}{2}$ the water using stoneware. Liquefy the oils at 120° F. vessel glass lined or stainless steel. Agitate slowly and run in the alkali, add alcohol and mix for $\frac{1}{2}$ hour, allow to stand over night and stir in the remainder of the water, age and filter. If made by the hot process follow the same procedure except after the addition of the alkali, the temperature is increased and maintained for $\frac{1}{2}$ hour or until saponification is complete. The following formula yields a clear amber product which does not become turbid upon standing: Coconut oil (best Cochun grade) 14%, caustic potash (90%) 6, caustic soda 0.5, oleic acid 10, glycerin 12, perfume oil 0.5, water 57. Dissolve the potash in $\frac{1}{4}$ of the water using a steel kettle. Melt the coconut oil, and at 130° F stir in the potash solution with constant mixing. Increase the temperature to 180° C and stir for an hour and allow to stand over night, then bring to a boil $\frac{1}{2}$ the remaining water and the glycerin. Add the coconut soap in small portions with constant slow stirring until dissolved, heat the remaining water to boiling, add the sodium hydroxide and stir this solution into the soap, heat the oleic acid to 160° F and add to the soap solution with agitation. Mix until tests show complete saponification. The finished soap may be run through a homogenizer or colloid mill and chilled to 32° F producing a product which will not become cloudy after bottling. *Olive Oil Shampoo*—Olive oil 8%, palm oil 4, coconut oil (Cochun) 8, caustic potash (90%) 5, alcohol 8, water 58, glycerin 6, oleic acid 2.5, perfume 0.5. Warm the oils to 120° F and dissolve the potash in $\frac{1}{4}$ the water and stir into the oils, heat the mixture to 180° stirring constantly, stir in the acid cool to 110°, stir in the alcohol and perfume, allow to stand over night and add the remainder of the water mixed with the glycerin. Age or chill and filter. Equipment necessary for this type of manufacture is mentioned—ANON *Drug and Cosmetic Ind* 37 (1935) 39-40 43-44

(H M B)

Shaving Soap The following formulas and procedures for modern shaving soaps are offered: (1) *Shaving Cream*—Triple pressed stearic acid 26%, coconut oil (Cochun) 8%, cetyl alcohol 5%, sodium hydroxide (85%) 0.75%, potassium hydroxide (85%) 9%, glycerin 9%, boric acid 1%, water 40.75%, oil of lavender 0.5%. Weigh out the stearic acid and divide into 2 equal parts, put one part into a steam-jacketed kettle, add the coconut oil and heat to 180° F, put the other portion of the acid and the alcohol into another kettle and melt. Dissolve the boric acid in water and set aside, dissolve the alkalis in the remainder of the water. To the stearic acid and coconut oil melts add the alkalis slowly mixing and maintaining the temperature for 20 minutes, add the glycerin and boric acid solution mix for 10 minutes, add the remainder of the stearic acid and cetyl alcohol slowly, remove heat and mix for one hour, add the perfume oil, age for one month with occasional stirring. By reducing the amount of cetyl alcohol, anhydrous lanolin, lecithin or cholesterol may be added. The final product dissolved in warm alcohol should not show more than a pale pink to phenolphthalein. (2) Beef tallow 6%, triple pressed stearic acid 25%, coconut oil (Cochun) 10%, lanolin 2%, cholesterol 0.25%, glycerin 7%, boric acid

PHARMACY

Nov 1935

Product	Purpose	Properties	Primary Composition	Formulas		
				Me-	Light	Heavy
1 Face Powder	Cosmetic to improve texture color and finish of the skin. Cover minor imperfections.	Color, to match and flatter skin is of paramount importance. Perfume must be attractive. Should have covering power, be adherent, apply smoothly, hold odor, not clog pores.	May consist wholly or in part of powder bases. Pigments give covering power, slip given by talc, covering bases, etc. Metallic powder bases, increase adhesion, ppd soaps increase adhesion, and absorbent chalk acts as binder and absorber of perfume. Materials must be finely dispersed and color well mixed. Light, heavy and medium refer to covering power and type of skin.	Zinc oxide Titanium Oxide Kaolin Zinc stearate Talc Magnesium stearate Precipitated chalk Mag carbonate Perfume Color 9 5	22 00 4 00 20 00 6 00 65 00 3 00 6 00 6 00 1 00	3 00 20 00 4 00 66 00 66 00 3 00 6 00 1 00 1 00
2 Compact Powder	Same as Face Powder	Color, perfume covering power, adhesion, slip are important. Cake should be smooth, reasonably hard, non-crumbing. Should rub off onto puff smoothly and easily.	Suitable face powder formula with addition of binder. May be molded or pressed. Finished cake should be smooth with satin finish. Gum or resin (1%) in water as binder.	Talc Kaolin Starch Zinc oxide Liquid binder Titanium oxide Cetyl alcohol Color and perfume	37 00 25 00 33 00 5 00 10 00 7 00 1 00	54 00 26 00 9 00 10 00 10 00 7 00

1.5%, sodium hydroxide (85%) 8%, potassium hydroxide (85%) 0.75%, water 30%, menthol 0.1%, perfume 0.4%. The procedure is the same as in (1), the lanolin and cholesterol being melted with the second portion of the stearic acid and the menthol added with the perfume —
 ANON *Drug and Cosmetic Ind.*, 37 (1935), 181-182 (H M B)

Tooth Paste The following parts of a tooth paste are discussed: (1) polishing agents as chalk, tricalcium phosphate, calcium sulphate, magnesium and magnesium carbonate, (2) vehicles including glycerin, alcohol and water, (3) binders to prevent separation and give colloidal protection such as tragacanth, starch as the glycerite, Irish Moss as the mucilage, acacia and bentonite. Tragacanth is to be preferred and is prepared (a) glycerite of the gum (10%), glycerin 78% and water 12%. Heat until clear on the water bath, or (b) by the cold method mixing the gum with glycerin and allowing to stand and (c) allowing the gum to swell with water and stirring until a smooth paste is obtained, (4) 1% mineral oil is added, (5) sweeteners such as saccharine, (6) potassium chlorate (10% or more), sodium bicarbonate, camphor, silica gel, cuttlefish bone, kaolin, talc, etc., are sometimes used, (7) color of the paste should be creamy white, erythrosine is used to give a pink paste and (8) flavors such as the oils of peppermint, spearmint, cassia, cloves, pimenta, anise, cardamom and eucalyptus, menthol and thymol. Necessary equipment for preparing is a mixer, sifter and ointment mill. The following formulas are offered: (1) precipitated chalk 40%, tricalcium phosphate 6%, white soap powder 2%, mucilage of tragacanth 5%, soluble saccharine 0.1%, mineral oil 1%, glycerin 15%, water 30.4% and flavor 0.5%. Soak the gum in $\frac{1}{2}$ of the water and place in a mixer with the remainder of the water and glycerin. Stir and add the sifted powders containing the saccharine and add the flavor and mineral oil. Mix until smooth, mill through an ointment mill, allow to stand and then tube in the usual way. (2) Precipitated chalk 42%, neutral soap powder 10%, benzoic acid 1%, saccharine 1%, glycerin 25%, alcohol (specially denatured) 20% and flavor 1%. Dissolve the saccharine and flavor in $\frac{1}{2}$ of the alcohol and the benzoic acid in the rest of the alcohol. In the mixing machine place the glycerin and add the alcohol solution of the acid passing through a strainer. Now add the other alcohol solution, agitate well, add $\frac{1}{2}$ of the chalk and mix, add the soap, mix and then add the rest of the chalk. Mix and mill. (3) Acid Dental Cream: tricalcium phosphate 23%, calcium sulphate 35%, glycerin 25%, water 10%, glycerite of tragacanth 4%, mineral oil 1%, acid 0.1%, sodium lauryl sulfonate 0.5% and flavor 1.4%. Prepare the glycerite by the heat method, place with the glycerin in a mixer and mix, add the calcium salts, mix, add the sodium salt and the flavor containing the saccharine, then the mineral oil. All powders should be free from carbonates. (4) Milk of Magnesia tooth paste: Milk of magnesia 24%, precipitated chalk 32%, white powdered soap 2%, glycerite of tragacanth 10%, glycerin 10%, water 20%, mineral oil 1%, saccharine (soluble) 0.1% and flavor 0.9%. Mix the glycerite, glycerin and water, add $\frac{1}{2}$ of the chalk, mix, add the milk, mix, then the soap and the remainder of the chalk and the flavor containing the saccharine, mix well and mill. Time can be saved in making the milk of magnesia by using pulverized magnesium oxide, add water, allow to stand and pass through a colloid mill. Creams may be tested by placing in freezing mixtures, in an oven at 100-110° F in a window. After three weeks the preparation should remain creamy, uniform and soft — J W WILLIAMS *Drug and Cosmetic Ind.* 37 (1935) 31-32, 44 (H M B)

DISPENSING

Fluidextract of Ergot in a Mixture Considerable doubt exists as to the best means of dispensing Liquid Extract of Ergot of the B. P., 1932 and as to the value of the preparation when dispensed in the form of a mixture. In January 1933, Dr. J. H. Burn made the statement that "Extractum Ergotæ Liquidum must be given alone and it cannot be included in general prescriptions if the desired therapeutic result is to be obtained." Dr. B. L. Stanton submitted the following formula for trial as a Quinine, Ergot and Strychnine Mixture: Ext. Ergot Liq. B. P. '32 M xv, Quinin Dihydrochlor. gr. v, Tr. Nuc. Vom. M. xv, Tr. Aurant. M. xv, Glycerin, ad Z ii. The object of the present work was to determine whether this mixture would keep for a sufficient length of time without loss of activity due to alteration of the ergotoxine, for the mixture to be of practical value. A period of fourteen days was taken as a reasonable length of time, as normally such a mixture would be used in that time. A sample of mixture made according to Dr. Stanton's formula was prepared and after storage under ordinary conditions of light and temperature has remained clear after 15 months. A sample of Liquid Extract of Ergot was obtained and assayed

by the B P method From the extract a sample of Quinine, Ergot and Strychnine Mixture was prepared according to the above formula and assayed by the same method as the extract After 14 days, the Liquid Extract of Ergot and the mixture (without quinine) were again assayed A loss of 12.9% of the original amount of ergotoxine present had occurred in both cases The mixture suffered no greater loss in alkaloidal content than the Liquid Extract of Ergot—E. E. NIEL *Australasian J Pharm*, 16 (1935), 385 (T G W)

Medicines for Injection—Physiological and Physico-Chemical Considerations in the Preparation of A lecture, concerned chiefly with the question to what degree the pharmacist can and should take into account physicochemical and physiological considerations in preparing medicines which are to be injected In particular the question of making the hydrogen ion concentration of the preparation approach that of the blood is discussed The question of isotonicity and that of sterility are also considered A signature label is proposed for use by the pharmacist who attempts to employ these considerations In the preparation of this medicine injection account has been taken of pH —Osmotic pressure—Sterility in so far as the properties of the preparation permit—S. A. SCHOU *Arch Pharm og Chem*, 42 (1935), 401 (C S L)

Solution of Methenamine and Ammonium Chloride A formula is cited for preparation of a solution recommended by Prof. E. Warburg for acidifying the urine, called *Mixt Methenamin ammoni chloridi* This consists of ammonium chloride 80 Gm methenamine, 12 Gm *Tinctura Auranti dulcis* 10 Gm and distilled water 300 Gm—ANON *Arch Pharm og Chem*, 42 (1935), 450 (C S L)

PHARMACEUTICAL EDUCATION

Biology for Pharmaceutical Students A discourse on the vocational use and foundations of a training in biology for pharmaceutical students—F J DYER *Pharm J*, 135 (1935), 185

(W B B)

Pharmacist—Education of the The reform in the education of the pharmacist in Hungary has not only been along pharmaceutical lines but also along cultural, sanitary and other lines. The author has compiled the requirements of 28 countries. In 20 of the 28, the education of the pharmacist begins with a university course, which method seems more reasonable than the systems in which apprenticeship in a pharmacy is the first step. Of the countries studied 9 require 6 semesters of school work, 11 require 8, 4 require 9 or 10, 1 requires 5 and only 3 require 4 semesters. In 8 countries the pharmaceutical faculties are of university standing and in 4 they are of high school standing. The second table shows the individual subjects along with the required number of credit hours for 17 countries. The third table shows the subjects and the number of credit hours required in the course in pharmacy in Hungary. The pharmacist should be equipped along several lines so that he may be of service to practicing physicians, and in small towns he must also be acquainted with farming necessities of a chemical nature such as fertilizers and the like—S MOZSONYI *J Hungarian Pharm Assoc*, through *Pharm Presse*, 40 (1935), 309

PHARMACEUTICAL LEGISLATION

Drug Code—Brief History of This history is traced from the authorization of a Committee on the Retail Drug Code by the National Association of Retail Druggists, following the enactment of the National Industrial Recovery Act down to time of the decision of the Supreme Court in the Schechter case. At the final meeting of the National Code Authority, June 8, 1935, it was decided to place all records in the keeping of the secretary for one year and then to turn them over to the AMERICAN INSTITUTE OF PHARMACY for such historical use as can be made of them—E F KELLY *J Am Pharm Assoc*, 24 (1935), 767

(Z M C)

Pharmacopœia of the United States and the Federal Food and Drugs Act Attention is directed to the primary purpose of a pharmacopœia and the origin and method of revision of the U S P is discussed. Reasons why the Pharmacopœia should not be deleted from the Federal Food and Drugs Act are explained. What is meant by a 'variation clause' is explained and the question whether reference to the U S P in the Federal Food and Drugs Act may be coupled with the variation clause is discussed at some length. That the variation clause is necessary to permit improvement in pharmaceutical substances is explained and also the relation of this clause to the delegation of legislative power. In many cases titles employed to designate U S P substances are taken from the English Language and such names cannot be copyrighted. The primary purpose of a food and drugs act is to prevent fraud. The author summarizes his arguments as justifying the following conclusions: 1 That a Federal Food and Drugs Act as represented by the Copeland Bill applies exclusively to foods and drugs while they are within the domain of interstate commerce. By the use of no language can the Federal law be made to apply to commerce after it has lost its interstate character. After once mingling with the goods of a particular state, only the laws of such state can fix the qualities which drugs must possess in order to permit their lawful distribution therein. 2 That the definitions for drugs, and for adulterated and misbranded drugs as found in the Copeland Bill are such that without the addition of a proper variation clause, only such drugs as complied with U S P standards of strength, quality and purity could be lawfully transported in interstate commerce a condition which if it prevailed would prevent the shipment of hundreds of thousands of tons of drugs and chemicals commonly used in the arts and industries. 3 That each new revision of the U S P presents numerous changes in the standards of strength, quality and purity of the drugs described in its monographs and also introduces new drugs and preparations which were not commonly used or even known when the preceding volume was issued. If the law making body confers upon the revisers of the Pharmacopœia blanket authority to change the legal obligations of the citizen so as to render him liable to fine and imprisonment for acts which would have been innocent in law if the Pharmacopœia had not been revised, it would seem fairly evident that there has been an attempted delegation of law-making power. On the other hand if the law permits the use of U S P titles which are parts of common English speech upon articles not of U S P standards, upon

condition merely that the label states the fact of such variation, then no new obligation is forced upon the producer when a new Pharmacopœia becomes official. Under any revision of the Pharmacopœia his legal liability remains the same, he will always have the option either of observing U S P standards or of stating upon the labels wherein his product differs from such standards. 4 That it is the common understanding among physicians and pharmacists and taught in all colleges of pharmacy, that the use of a U S P title without the addition of qualifying adjectives or other explanatory words, implies that the product to which it is attached complies with U S P standards of strength, quality and purity. Unless this be the rule, the primary purpose of the Pharmacopœia—to enforce uniformity in properties and potency—would be defeated. 5 That a proper variation clause is one which would require that when a U S P title is attached to a drug of other than U S P standards the qualifying words shall indicate clearly that the drug does not profess to comply with such official standards. The wording of the label should not be obscure or ambiguous, but such as to enable the reader to form an intelligent opinion as to the character of the product. 6 And finally, that the deletion of the variation clause from the Federal Food and Drugs Act would not close interstate commerce to the shipment of medicinal preparations of official drugs which did not comply with U S P standards. The producer would need only to give his product some attractive coined name and ship it as a proprietary specialty, thus setting his own standards, without let or hinderance from any authority."—J H BEAL *J Am Pharm Assoc* 24 (1935), 759 (Z M C)

Pharmacy in Denmark. A discussion of the changes taking place in pharmacy administration in Denmark.—W MATR *Pharm J*, 135 (1935), 254 (W B B)

Vitamin and Organotherapeutic Preparations, Standardized. The Question of Their Unrestricted Commerce in the Wholesale Pharmaceutical Trade. A lecture before the Nordiska Apothecaries and Pharmaceutical Meeting of 1935 in Stockholm discussing state regulation and control especially of vitamin preparations and gland preparations. Thyroid gland is not considered satisfactorily controlled by chemical means and the biological method of Krogh and Lindberg is recommended. It is noted however, that the biological methods are still in dispute and that probably the chemical method approved by the Permanent Standards Commission of the League of nations will remain more convenient to use. Vitamin A and D concentrates such as halibut liver oil, Calciferol, B vitamin preparations such as rice polishings extracts, yeast extracts and liver extracts are cited as examples of preparations needing biological control. The problem of cost to the state is considered.—J K GALBRAEK *Arch Pharm og Chem* 42 (1935), 427, 441 (C S L)

MISCELLANEOUS

Pharmacist and the Podiatrist. The opportunities for pharmaceutical work in supplying the podiatrist or chiropodist are hardly touched. A considerable number of substances and formulas are listed. The classification indicates the scope. Dusting powders, emollients, massage preparations, karyolytics—preparations for softening of abnormal growths, escharotics, preparations used in the treatment of ring worm infections, hyperhidrosis and bromidrosis, skin stimulants.—W F AMBROZ *J Am Pharm Assoc*, 24 (1935), 774 (Z M C)

Professional Pharmacy and Chemical-Pharmaceutical Industry in the Soviet Union.—State of Impressions from a Tour. A detailed account of the impressions gained by a Swedish apothecary on a tour in the Soviet Union studying the organization of the professional apothecaries, service and the state of the chemical and pharmaceutical industry. Both the public apothecaries and the hospital dispensaries are considered, also the schools of pharmacy especially the Moscow Institute or College. There are in the Union 126 schools awarding the assistant's certificate and three 'high schools' or colleges of higher study. The Moscow Institute trains both apothecaries' assistants and physicians' assistants. The three year pharmacy course is open to students over 16 and under 35 years of age who have had at least seven years of lower school. After passing the assistant's examination three years of practice in an apothecary shop are required before the candidate may enter higher studies. At least two years of study for the higher degree are necessary. The subjects of curriculum are cited. The Moscow Institute has about 150 teachers and 1400 students. Descriptions of visits to Russian pharmaceutical industrial works are also of interest. At one works digitalis and adonis glucoside extraction, manufacture of chloroform, and synthesis of plasmochin, bromvalerylurea, diethylmalonylurea, sajodin, phenylcinchonic acid

At one works digitalis and adonis glucoside extraction, manufacture of chloroform, and synthesis of plasmochin, bromvalerylurea, diethylmalonylurea, sajodin, phenylecinchonic acid

and other drugs were observed and also the manufacture of photographic chemicals was seen. At a manufacturing pharmacy works, various organic and inorganic drug preparations were seen in manufacture. At this works 300-400 different varieties were made. The staff here numbered about 1000 workers. Large and well-equipped control and experimental laboratories were attached. The working men's recreation house is described with dining hall, amateur theater, library of 6000 volumes, school rooms including a chemical laboratory, etc. A factory making bandage and other first-aid equipment was also visited. The State Chemical Pharmaceutical Research Institute in Moscow is also described. Here about 120 academically trained scientific workers, many with one or two assistants, were found engaged in research. In one division twenty physicians were employed in therapeutic research. Among the various fields of research one laboratory was set aside for alkaloid research, another for research on analysis of organic compounds, others for inorganic and for electrolytic analytical research. A rare earth research laboratory was noted. Sufficiently large scale apparatus was available so that new chemical compounds might be prepared in quantities sufficient for clinical testing when that stage was attained. New pyridine and acridine preparations were seen in preparation. The latter was an agent for treatment of malaria called 'Akrikirin'. The pharmacological division of the Research Institute with its animal house, etc., was also inspected.—T. WIKANDER *Farm Revy*, 34 (1935) 477, 489 501 513 526 542 (C S L)

PHARMACOLOGY TOXICOLOGY AND THERAPEUTICS

PHARMACOLOGY

Alcohol Injected Intravenously—Effect of Habituation on Rate of Metabolism. A daily intake of from 5 to 7 cc. of alcohol per Kg. for a period of three months does not result in an increased rate of alcohol metabolism in the dog. Since it has been shown by others that absorption of alcohol is increased rather than decreased by habituation, we are left with the factor of increased tissue resistance to explain acquired tolerance to alcohol, if such exists in fact. Direct evidence that such tolerance exists is wanting.—HENRY W. NEWMAN and WINDSOR C. CUTTING. *J. Pharmacol.* 55 (1935) 88 (H B H)

Alkaloids of Fumariaceous Plants—Pharmacological Action of II. Corydine. The effects of corydine on intact animals, animals arranged for recording blood pressure, the isolated uterus and the isolated heart have been studied. In the intact animals an initial stage of drowsiness followed by drowsiness alternating with fibrillary twitches in isolated muscles was demonstrated. In larger doses the animal developed strychnine-like convulsions which involved the muscles of respiration resulting in death due to asphyxia. Injected intravenously in rabbits corydine produced an initial fall in blood pressure followed by a return to normal or above normal. Added to a bath containing the excised uterus, corydine produced increased tone and height of contraction. The perfused frog's heart showed increased tone and considerable slowing.—R. A. WAUD. *J. Pharmacol.*, 55 (1935) 40 (H B H)

Amytal and Amidopyrine—Effect of, on Blood Picture of the Albino Rat after a Deficient Diet. The white blood count of rats, weakened by a deficient diet, may be reduced approximately 50% by oral administration of amytal and amidopyrine. Granulocytes do not disappear from the blood stream.—ERMA SMITH and L. MACK. *Proc. Soc. Exptl. Biol. Med.*, 32 (1935) 1623 (A D M)

Arsenicals, K 324 and K 352—Trypanocidal Action of, on Infections in Mice and Rabbits. A comparison of the trypanocidal action of K 324 (I, p-NH-CO-C₆H₄-As (SCH₃CH₃(NH)COOH)) K 352 (II, 2-(diglutathionylarsyl) 5-acetamido phenol) and sodium N-carbamyl methylarsanilate (III, tryparsamide). The maximum tolerated dose by a single slow intravenous injection of an approximate neutral solution was 0.075-0.2 and 3-3.5 mg./g. of mouse. Trypanosome infections in mice varied somewhat in the ease with which they could be cured. The order of increasing difficulty of cure was *T. brucei*, *T. rhodesiense* and *T. equiperdum*. The therapeutic index (minimum curative dose/maximum tolerated dose) for the respective trypanosomes was with I 1/10, 1/7.5 and 1/3.75; with II 1/20, 1/20 and 1/10. Doses of 0.01 mg./g. or more of I or II and of 0.75 mg./g. of III cleared the peripheral blood of *T. gambiense* infections for long periods. Relapses were common after treatment with 0.005 mg./g. of I or II. Negative findings in the peripheral blood did not necessarily indicate freedom from *T. gambiense* infection.

Trypanosomes may be present in the brain circulation without untoward signs of infection. No curative value of I or II for *T. congolense* infections in mice was apparent. It was found that a total dose of 0.03 g/Kg of I in 3 injections, 0.04 g/Kg of II in 4 injections and 0.75 g/Kg of III in 3 injections would effect permanent cures of rabbits infected with *T. rhodesiense*. Thus only 2-3% as much as in the form of I or II is required as in III. Permanent cures in rabbits were produced, though less effectively, by single intravenous injection of 0.015-0.02 I/Kg or 0.02-0.04 g II/Kg.—WINIFRED I. STRANGEWAYS *Ann. Trop. Med.*, 29 (1935), 231, through *Squibb Abstract Bull.*, 8 (1935), A-1360.

Dialkylaminoethoxyethyl-*p*-aminobenzoates—Local Anesthetic Action of Dialkylaminoethoxyethyl *p*-aminobenzoates of the general formula $p\text{-H}_2\text{NC}_6\text{H}_4\text{COOCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{NR}_2$ where R was methyl, ethyl, *n* propyl and *n* butyl radicals were prepared and their toxicity, intracutaneous and surface anesthesia and irritation were determined. The dimethyl derivative did not cause topical anesthesia. Toxicity and anesthetic action increased as R increased. They showed no irritation. Their preparation and physical properties are given.—LEONE A. RUBERG and R. L. SHIRNER *J. Am. Chem. Soc.*, 57 (1935), 1581 (E. B. S.)

Digitalis, Strophanthus and Squill—Use of Rabbits in Assay of. Study has been made of the value of rabbits for the assay of strophanthus, digitalis and squill. The rabbit is less sensitive than the cat to ouabain, strophanthus or squill, but more sensitive than the dog or guinea pig to the two former. To digitalis it is the most resistant of these four species. The advantages of the use of rabbits lie in the short duration of each experiment, and the ease with which a stock of animals can be obtained. The disadvantage is the fact that to attain the same degree of accuracy more animals must be used on each test. Where comparison has been made results obtained on rabbits agree with those obtained with the use of cats.—G. N. RAPSON and S. W. F. UNDERHILL *Pharm. J.*, 135 (1935), 797 (W. B. B.)

Diphenyl Compounds—Therapeutic Substances Derived from Unsymmetrical III. Some Aryl Esters of the Hydroxy Diphenyls. A number of aryl esters of 2, 3- and 4-hydroxy-diphenyls and some of their substitution products were prepared. The hydroxy diphenyls (*o*, *m*- and *p*-phenyl phenol) are active, non-toxic germicides and it was hoped that by oral administration in the form of ester they might reach the urine unmetabolized and there exert germicidal action. Fifteen esters were made and tested. Experimentation on animals showed that they have no value as urinary antiseptics. Rabbits were used. The compounds with their crystallizing media, their melting points and analyses are listed.—S. E. HARRIS and W. G. CHRISTIANSEN *J. Am. Pharm. Assoc.*, 24 (1935), 553 (Z. M. C.)

Epithelial Anesthesia. Experiments on humans affected with solar burns indicated that of the various alkyl *p*-aminobenzoates the ethyl derivative (benzocaine) when administered in oil failed to produce sufficient anesthesia to allay the pain, the propyl and butyl derivatives showed very little difference in their action and afforded the patient practically complete relief, the amyl derivative was not studied since with an increase in the molecular weight of the alkyl radicle there is increased difficulty and expense in manufacture and increased potential epithelial irritation. Evidence indicates that the greater the solubility of the derivative in the oil, the greater the action on the epidermal tissue, the greater the solubility in water the greater the action on the intact mucous membrane. An anesthetic of the quinoline group induced action more rapidly but after 1/2 hour no difference could be determined from that produced by the propyl derivative. Substitutions or additions in the amine or alkyl radicle result in a diminution of the action.—L. STAMBOVSKY *Drug and Cosmetic Ind.* 37 (1935), 175-176, 192 (H. M. B.)

Ergometrine—Concerning Some Pharmacological Effects of. Crystalline ergometrine was tested on a dog using the method utilizing the power of the ergot alkaloids for paralyzing the adrenaline sensitive renal vasoconstrictors. It was shown to act similarly to the other ergot alkaloids but required a greater quantity than ergotoxine or ergotamine to produce the same action which, however, was more lasting.—RAYMOND HAMET *Compt. rend.*, 201 (1935), 176 (G. W. H.)

Ether—Studies on Dosage of, after Pre-anesthetic Medication with Narcotics (Barbiturates, Magnesium Sulphate and Morphine). Dogs were used as experimental subjects, and ether administered both by the open mask method and by the use of the Forreger apparatus. Determinations were made as to the blood ether concentration during the stage of surgical anesthesia and stoppage of respiration when ether was administered in combination with various

hypnotics The margin of safety in ether anesthesia is neither increased nor decreased by preliminary medication with sedative doses of morphine or the barbiturates mentioned It is lessened with magnesium sulphate The advantage of giving morphine or the barbiturates lies in the mental and physical relaxation they produce—FRANK A CALDERONE *J Pharmacol*, 55 (1935), 24 (H B H)

Liver and Stomach Preparations—Assay of The assay is based on decrease in erythrocytes under the influence of phenylhydrazine-anemia Animals of equal weight are fed the same diet and the number of erythrocytes in the blood determined Two or three days later, all animals receive a subcutaneous injection of 16 mg phenylhydrazine hydrochloric acid (1% aq solution) per Kg and thereupon also a subcutaneous or oral dose of the antianemic substances 1-2 animals serving as controls The antianemic principle is given only once, each animal receiving a different dose or every 2 animals the same dose The decrease in the erythrocyte number reaches its maximum in 48-72 hrs after injection in the controls, while in the animals treated with liver or stomach preparations the maximum appears 96-120 hours after injection, i e., about 48 hours after the control maximum Assaying and comparing of active preparations are made on this basis—JOSEPH ERDOS *Biochem Z* 277 (1935) 342, through *Squibb Abstract Bull* 8 (1935), A 806

Male Sex Hormones—Biological Evaluation of the A review—J W JUNG *Apolh Ztg*, 50 (1935), 525-526 (H M B)

Pentobarbital, Chloral Hydrate and Avertin—Relative Efficacy of a Series of Analeptics as Antidotes to Sublethal and Lethal Doses of The antidotal efficiency of artificial respiration, of an atmosphere of 10% carbon dioxide, and medication with picrotoxin, metrazol "coramine," caffeine, cocaine, strychnine, sodium 2,4-dinitrophenol "icoral," nicotine and combinations of ephedrine and the more effective of the agents was noted upon adult albino rabbits to which had been given either pentobarbital, chloral hydrate or avertin Sixteen hundred experiments were performed from which the following conclusions were drawn All procedures tested were found to have more or less symptomatic value in antidoting temporarily the depressant effects of the hypnotics The degree and duration of action of each analeptic was inverse to the depth of hypnosis and with few exceptions, the order of antidotal efficiency of the series of agents or procedures was the same for each of the hypnotics The order of practical usefulness of the several therapeutic measures judged by the degree of improvement in respiration, circulation and reflex excitability, degree of shortening of the usual stages of recovery and the margin of safety of effective dosages of each agent, from high to low is as follows picrotoxin metrazol, ephedrine, artificial respiration, "coramine," icoral, strychnine and caffeine sodium-benzoate Large to lethal doses of each of the hypnotics produce significant depressive effects on respiration and the circulation The most satisfactory therapeutic measures therefore, included combined medication with ephedrine and either picrotoxin, metrazol or "coramine" Tolerance to these preparations parallels the degree of depression present, particularly with the convulsants The dosage and frequency of administration of the antagonists must be gaged by the duration of the optimal response observed and the relative need for supportive treatment Artificial respiration especially with gas mixtures containing 5 to 10% of carbon dioxide is highly effective as a single resuscitation measure against lethal doses of these hypnotics This procedure because of its safety and high degree of effectiveness after paralysis of the respiratory center is considered to be of outstanding usefulness either alone or in conjunction with other analeptic measures Ephedrine is particularly effective in modifying the effects of sedative to moderately toxic doses of avertin or chloral hydrate primarily because of the circulatory depressant effects of these hypnotics However, large doses of ephedrine should be used with caution in avertin or chloral poisoning in that an added depression may occur This alkaloid on intravenous administration tends to produce cardiac irregularities and occasionally pulmonary edema Caffeine in dosages far exceeding those used clinically moderately improved the respiration of animals depressed by these hypnotics Excessive doses of this alkaloid produced in addition to the initial stimulant action, a secondary depression which was additive with that of the hypnotics Artificial respiration is definitely superior to caffeine as a therapeutic measure in antidoting single 100% lethal doses of pentobarbital—O W BARLOW *J Pharmacol* 55 (1935) 1 (H B H)

Pharmaceutical Research—Application of Statistical Methods to IV Methods of Recording Drug Action Interpretation of minimum effective dose (MED) minimum tolerated dose (MTD) or minimum lethal dose (MLD) absolute lethal dose (ALD) or certain lethal

dose (CLD) is discussed. Different interpretations make it impossible to compare results of different investigators. Variability expressed in terms of a "standard curve" proved a good thing. Trevan proposed the "LD₅₀" dose as a basis of measurement, that is, a dose affecting half the test animals. The present paper reports on aconitine, picrotoxin, morphine and strychnine. Tabulations of dosage as well as graphs are shown. "By using a subscript before the statement of effect to indicate the number of animals employed and another after it to indicate the degree of response used as a criterion ($\frac{LD_{50}}{n}$), drug action may be quantitatively recorded with maximum convenience and minimum labor"—J. C. MUNCH and F. E. GARLOUGH. *J. Am. Pharm. Assoc.*, 24 (1935), 619 (Z. M. C.)

Progesterin, Crystalline—Inhibition of Uterine Motility with, in Vivo. In experiments with rabbits with uterine fistulas to allow tractions, A. and R. found that impure corpus luteum extracts containing progesterin completely inhibited uterine motility in 1 hr. after injection of 12 rabbit units in 2 hrs. with 0.6 units and 4 hrs. with 0.3 units. With the pure prismatic form of the hormone, inhibition occurred in 3.75 hrs. with 0.2 rabbit unit (0.26 mg.) and in 2.5 hrs. with 0.4 unit. Injection of the pure needle form of progesterin gave similar results. Thus the 2 crystalline forms of the hormone showed no physiological differences, both being able to suppress uterine motility. Since the pure hormone and the impure extract both had the same inhibiting capacity per rabbit unit, both inhibition of motility and progesterinal proliferation of the endometrium were caused by the same hormone.—WILLARD M. ALLEN and SAMUEL R. M. REYNOLDS. *Science*, 82 (1935), 155, through *Squibb Abstract Bull.*, 8 (1935), A 1368.

Saliva Tests. III. Detection of the Administration of Some Opium Derivatives to Horses. Reference is made to previous reports of a method for detecting morphine and heroin in saliva of horses after subcutaneous or intramuscular injection of known drugs. Thresholds for mouse tests are given for the following alkaloids: morphine, codeine, dihydromorphine, dihydromorphine, dihydromorphine and heroin. Normal salivas from over one hundred untreated horses have been injected into mice and none had an effect resembling that of opium alkaloids. Since "doping" of horses is not permitted by Racing Commissions it seemed advisable to conduct experiments simulating race-track conditions. Twenty horses were injected subcutaneously with colorless solutions, the composition being unknown to investigators. Gelatin capsules, whose contents were unknown, were administered by mouth to seventeen horses. Details of procedure are reported. Based upon the observations on mice an attempt was made to answer two questions: "(1) Do the mouse tests on salivas from a horse suggest that the animal has been 'doped,' (2) If 'doped,' was a large or small amount of drug administered?" After opinions as to "doping" and dose were recorded code numbers were consulted. These results were tabulated. Opinions of veterinarians did not always agree. The mouse tests were correct in every instance both as to whether horse had been doped and size of dose. Further experimentation was conducted after the horse had been galloped two miles and saliva sample collected an hour and a half after administration. At the end of a week and after two months, these samples gave positive results. Veterinarians were unable to observe abnormalities in the horse. Further tests indicated that morphine is somewhat more potent than a corresponding dose of opium. Pantopon was moderately effective. Studies are being continued to try to find characteristic symptoms for each product. At present information does not permit identification in all cases.—JAMES C. MUNCH. *J. Am. Pharm. Assoc.*, 24 (1935), 557 (Z. M. C.)

Testicular Hormone—Assay for, by the Comb-Growth Reaction. II. The direct measurement of the increases in height and length of the capon comb is easily reproducible. The differences in these values as determined independently by two observers involving 548 measurements on two hundred and seventy-four capons range from 0 to 0.8 mm. with an average difference of 0.3 mm. The comb growth response after five daily injections is more satisfactory as a quantitative measure than after two daily injections. The initial size of the comb must be taken into account in evaluating the comb growth response to the male sex hormone. For the five-day assay method, this involves a correction of 0.17 mm. comb growth for every millimeter difference in the initial length of the comb. This correction value holds over the range of growth employed for assay purposes. The quantitative response of the capon's comb to a given dose is not seriously influenced by age and by repeated use in assays. The body weight of the capon influences the response slightly. A difference of 500 Gm. in body weight calls for a correction of 0.4 mm. in comb growth response after five daily injections. The "characteristic curve" expressing the relation of increase in length plus height to dosage of male hormone has been established with

hypnotics The margin of safety in ether anesthesia is neither increased nor decreased by preliminary medication with sedative doses of morphine or the barbiturates mentioned It is lessened with magnesium sulphate The advantage of giving morphine or the barbiturates lies in the mental and physical relaxation they produce—FRANK A CALDERONE *J Pharmacol*, 55 (1935), 24 (H B H)

Liver and Stomach Preparations—Assay of The assay is based on decrease in erythrocytes under the influence of phenylhydrazine anemia Animals of equal weight are fed the same diet and the number of erythrocytes in the blood determined Two or three days later, all animals receive a subcutaneous injection of 16 mg phenylhydrazine hydrochloric acid (1% aq solution) per Kg and thereupon also a subcutaneous or oral dose of the antianemic substances, 1-2 animals serving as controls The antianemic principle is given only once, each animal receiving a different dose or every 2 animals the same dose The decrease in the erythrocyte number reaches its maximum in 48-72 hrs after injection in the controls, while in the animals treated with liver or stomach preparations the maximum appears 96-120 hours after injection; e, about 48 hours after the control maximum Assaying and comparing of active preparations are made on this basis—JOSEPH ERDOS *Biochem Z* 277 (1935) 342, through *Squibb Abstract Bull*, 8 (1935), A 806

Male Sex Hormones—Biological Evaluation of the A review—J W JUNG *Appl Ztg*, 50 (1935), 525-526 (H M B)

Pentobarbital, Chloral Hydrate and Avertin—Relative Efficacy of a Series of Analeptics as Antidotes to Sublethal and Lethal Doses of The antidotal efficiency of artificial respiration, of an atmosphere of 10% carbon dioxide, and medication with picrotoxin, metrazol "coramine," caffeine cocaine, strychnine sodium 2,4 dinitrophenol "icoral" nicotine and combinations of ephedrine and the more effective of the agents was noted upon adult albino rabbits to which had been given either pentobarbital, chloral hydrate or avertin Sixteen hundred experiments were performed from which the following conclusions were drawn All procedures tested were found to have more or less symptomatic value in antidoting temporarily the depressant effects of the hypnotics The degree and duration of action of each analeptic was inverse to the depth of hypnosis and with few exceptions the order of antidotal efficiency of the series of agents or procedures was the same for each of the hypnotics The order of practical usefulness of the several therapeutic measures, judged by the degree of improvement in respiration circulation and reflex excitability degree of shortening of the usual stages of recovery and the margin of safety of effective dosages of each agent, from high to low is as follows picrotoxin metrazol, ephedrine, artificial respiration "coramine," icoral," strychnine and caffeine sodium-benzoate Large to lethal doses of each of the hypnotics produce significant depressive effects on respiration and the circulation The most satisfactory therapeutic measures therefore included combined medication with ephedrine and either picrotoxin, metrazol or "coramine" Tolerance to these preparations parallels the degree of depression present particularly with the convulsants The dosage and frequency of administration of the antagonists must be gaged by the duration of the optimal response observed and the relative need for supportive treatment Artificial respiration especially with gas mixtures containing 5 to 10% of carbon dioxide is highly effective as a single resuscitation measure against lethal doses of these hypnotics This procedure because of its safety and high degree of effectiveness after paralysis of the respiratory center is considered to be of outstanding usefulness either alone or in conjunction with other analeptic measures Ephedrine is particularly effective in modifying the effects of sedative to moderately toxic doses of "avertin" or chloral hydrate primarily because of the circulatory depressant effects of these hypnotics However, large doses of ephedrine should be used with caution in "avertin" or chloral poisoning in that an added depression may occur This alkaloid on intravenous administration tends to produce cardiac irregularities and occasionally pulmonary edema Caffeine in dosages far exceeding those used clinically moderately improved the respiration of animals depressed by these hypnotics Excessive doses of this alkaloid produced in addition to the initial stimulant action a secondary depression which was additive with that of the hypnotics Artificial respiration is definitely superior to caffeine as a therapeutic measure in antidoting single 100% lethal doses of pentobarbital—O W BARLOW *J Pharmacol*, 55 (1935), 1 (H B H)

Pharmaceutical Research—Application of Statistical Methods to IV Methods of Recording Drug Action Interpretation of minimum effective dose (MED) minimum tolerated dose (MTD) or minimum lethal dose (MLD) absolute lethal dose (ALD) or certain lethal

dose (CLD) is discussed. Different interpretations make it impossible to compare results of different investigators. Variability expressed in terms of a "standard curve" proved a good thing. Trevan proposed the "LD₅₀" dose as a basis of measurement, that is, a dose affecting half the test animals. The present paper reports on aconitine, picrotoxin, morphine and strychnine. Tabulations of dosage as well as graphs are shown. "By using a subscript before the statement of effect to indicate the number of animals employed and another after it to indicate the degree of response used as a criterion (nED₅₀), drug action may be quantitatively recorded with maximum convenience and minimum labor"—J. C. MUNCH and F. E. GARLOUGH. *J. Am. Pharm. Assoc.*, 24 (1935), 619. (Z. M. C.)

Progesterin, Crystalline—Inhibition of Uterine Motility with, in Vivo In experiments with rabbits with uterine fistulas to allow tractions, A and R found that impure corpus luteum extracts containing progesterin completely inhibited uterine motility in 1 hr after injection of 12 rabbit units in 2 hrs with 0.6 units and 4 hrs with 0.3 units. With the pure prismatic form of the hormone, inhibition occurred in 3.75 hrs with 0.2 rabbit unit (0.26 mg) and in 2.5 hrs with 0.4 unit. Injection of the pure needle form of progesterin gave similar results. Thus the 2 crystalline forms of the hormone showed no physiological differences both being able to suppress uterine motility. Since the pure hormone and the impure extract both had the same inhibiting capacity per rabbit unit, both inhibition of motility and progesterinal proliferation of the endometrium were caused by the same hormone.—WILLARD M. ALLEN and SAMUEL R. M. REYNOLDS *Science*, 82 (1935), 155, through *Squibb Abstract Bull.*, 8 (1935), A-1368.

Saliva Tests III Detection of the Administration of Some Opium Derivatives to Horses

Reference is made to previous reports of a method for detecting morphine and heroin in saliva of horses after subcutaneous or intramuscular injection of known drugs. Thresholds for mouse tests are given for the following alkaloids: morphine, codeine, diionine, dilaudid and heroin. Normal salivas from over one hundred untreated horses have been injected into mice and none had an effect resembling that of opium alkaloids. Since "doping" of horses is not permitted by Racing Commissions it seemed advisable to conduct experiments simulating race-track conditions. Twenty horses were injected subcutaneously with colorless solutions, the composition being unknown to investigators. Gelatin capsules, whose contents were unknown, were administered by mouth to seventeen horses. Details of procedure are reported. Based upon the observations on mice an attempt was made to answer two questions: "(1) Do the mouse tests on salivas from a horse suggest that the animal has been 'doped,' (2) If 'doped,' was a large or small amount of drug administered." After opinions as to "doping" and dose were recorded code numbers were consulted. These results were tabulated. Opinions of veterinarians did not always agree. The mouse tests were correct in every instance both as to whether horse had been doped and size of dose. Further experimentation was conducted after the horse had been galloped two miles and saliva sample collected an hour and a half after administration. At the end of a week and after two months, these samples gave positive results. Veterinarians were unable to observe abnormalities in the horse. Further tests indicated that morphine is somewhat more potent than a corresponding dose of opium. Pantopon was moderately effective. Studies are being continued to try to find characteristic symptoms for each product. At present information does not permit identification in all cases.—JAMES C. MUNCH, *J. Am. Pharm. Assoc.*, 24 (1935), 557. (Z. M. C.)

Testicular Hormone—Assay for, by the Comb-Growth Reaction II The direct measurement of the increases in height and length of the capon comb is easily reproducible. The differences in these values as determined independently by two observers involving 548 measurements on two hundred and seventy-four capons range from 0 to 0.8 mm with an average difference of 0.3 mm. The comb-growth response after five daily injections is more satisfactory as a quantitative measure than after two daily injections. The initial size of the comb must be taken into account in evaluating the comb growth response to the male sex hormone. For the five day assay method this involves a correction of 0.17 mm comb growth for every millimeter difference in the initial length of the comb. This correction value holds over the range of growth employed for assay purposes. The quantitative response of the capon's comb to a given dose is not seriously influenced by age and by repeated use in assays. The body weight of the capon influences the response slightly. A difference of 500 Gm in body weight calls for a correction of 0.4 mm in comb growth response after five daily injections. The "characteristic curve" expressing the relation of increase in length plus height to dosage of male hormone has been established with

greater accuracy For the most accurate observations, an absolute increase in comb size cannot be taken for the bird unit basis because the light factor influences the comb growth response remarkably Hence it is best to express all assays in terms of a standard preparation which is assayed in parallel with each set of unknowns —T F GALLAGHER and F C KOCH *J Pharmacol* 55 (1935), 97 (H B H)

Thyroid Glands—Culture of Entire The successful culture of 15 thyroid glands, 6 from cats and 9 from cocks, is described This is accomplished by means of a new apparatus (mechanical heart and lungs), using three nutrient media, one consisting of diluted blood serum, a second a solution of acid amines and a third a solution containing peptones In the first two liquids, the glands diminished in volume while in the third they showed a decided increase doubling in weight in 3 or 4 days —ALEXIS CARRÉL and CHARLES LINDERGII *Compt rend*, 201 (1935), 14 (G W H)

Trichlorethylene—Study of the Anesthetic Properties of In the course of another study the anesthetic properties of trichlorethylene were investigated Using albino rats, inhalation produced surgical anesthesia in four or five minutes Recovery was prompt Marked stimulation of skeletal musculature accompanied anesthesia Effect of treatment, along with control growth curve, is shown by chart High rectal injections of solutions on rabbits did not produce anesthesia but were exceedingly irritating to colonic mucosa Blood sugar level was determined on rabbits after inhalation anesthesia Mild hyperglycemia resulted Applied to sciatic nerve it did not block blood pressure or respiratory response of faradization —JOHN C KRANTZ JR, C JELFFE CARR and RUTH MUSSER *J Am Pharm Assoc*, 24 (1935) 754 (Z M C)

Ultraviolet Light—Investigation of the Protective Effect of Various Preparations against Five preparations (constituents not given) are tested for their protective power against ultraviolet light To avoid the variation in the intensity of light from the sun an ultraviolet lamp is used throughout, at a distance of 1 meter from the skin Rectangles are marked on the skin the spaces between covered with a material impervious to ultraviolet light, and the five preparations applied in equal amounts, one to each block and leaving one block uncoated as a control Photographs of the skin are taken at intervals of 2 1/2, 6 and 16 hours after exposure to the light Only one preparation (Dr Wild Balsam) showed any appreciable protective effect Plates accompany the article —S WILD *Schweiz Apoth Ztg*, 73 (1935), 413 (M F W D)

Valerian Root and Valerian Preparations—Assay of Using a biological assay in frogs, different types of valerian preparations are evaluated including infusions made in various ways, fluid extracts and tinctures The tinctures are reported biologically the most active, the fluid extract is next in order of activity and the ordinary infusions are least active The ash content moisture and volatile constituents of several commercial specimens of the root pulverized and sieved to different degrees of fineness are reported Methods of determining the essential oil content are also studied —A NILANDER *Farm Revy*, 34 (1935) 531, 548 560 (C S L)

Yohimbine—Non-modification of the Sympathetic Action of, by the Introduction of a Double Bond Apoyohimbine which differs from yohimbine by the introduction of a double bond into ring E, was injected into a dog and its power to antagonize the hypertensive and renal vasoconstrictor action of adrenaline measured From the results obtained, it was concluded that apoyohimbine differs only slightly from yohimbine in its action —RAYMOND-HAMET *Compt rend*, 201 (1935), 434 (G W H)

TOXICOLOGY

Alpha-Dinitro-*o*-Cresol—Toxic Reaction to A case of a toxic reaction to alpha dinitro *o* cresol (total dose 1.5 G in 11 days) in a 14.5 yr old obese patient is reported The symptoms were marked drowsiness, headache nausea, vomiting, swelling of the fingers and hands, an itching maculo papular rash, greenish yellow coloration of the sclera but no signs of jaundice of the skin or mucous membranes, and extremely dark colored urine in which bile could not be detected, the icteric index was 24.75 and the Van den Bergh reaction negative, indicating no true hepatic involvement —MURRAY B GORDON and MARK J WALLFIELD *Ann Internal Med*, 9 (1935) 198 through *Squibb Abstract Bull*, 8 (1935), A-1369

Antidote for Heavy Metal Poisoning—A New Stabilized The stabilized antidote for heavy metals is prepared as follows 2 liters of water are heated to boiling for one minute, 2 Gm of pure NaOH dissolved in one half of the volume, which after cooling is saturated with hydrogen

sulphide previously washed by passage through a suspension of calcium carbonate in water. In the remainder of the water is dissolved 2 Gm of magnesium chloride and 25 Gm of sodium bicarbonate. On cooling, the second solution is poured into the first and the whole saturated with hydrogen sulphide at -2° to -3° C. The solution is then stored in a refrigerator in 125 cc flasks fitted with rubber stoppers, tied in and paraffined. This preparation can be kept for three years without deterioration. The author describes the physical and chemical properties of the antidote, a method of standardizing it, and the metals for which it may be employed. The antidote when taken orally produces only temporary discomfort and is relatively non-toxic. It may also be used to wash heavy metal salts out of the eyes. To test the efficacy of a three-year-old sample, the author drank 50 cc of solution containing 0.2 Gm mercuric chloride and then 50 cc of the antidote. With the exception of some irritation of the throat, none of the characteristic symptoms of mercury poisoning was evidenced, and in 5 days the throat soreness had cleared up. — C STRZYLOWSKI *Scientia Pharm*, 6 (1935) 94 (M F W D)

Arsphenamine Poisoning—Occurrence of, among Negro Women Of 14 cases of arsphenamine dermatitis observed by the authors in 1930–1934, 11 occurred in negroes. The average dosage of the arsenical was 0.45 Gm and the patients averaged 4.5 doses of neoarsphenamine before the reactions were sufficiently severe to interrupt treatment. Two of the cases were fatal. Nine of the 11 cases showed a marked generalized exfoliative dermatitis and 8 showed an accompanying pruritis. Epinephrine (adrenaline) injections gave a marked relief from the pruritis; in 1 case 5 minims gave complete relief for 4 hrs. Two of the patients developed no skin lesions and were the only 2 who had no pruritis but had a high icteric index. Fever appeared early in some cases and lasted indefinitely but the nature of the causes was undetermined. All except 1 case showed abnormally high eosinophile counts. Since symptoms and skin changes in the negro are frequently unobserved or unheeded, the physician is occasionally unable to prevent a fatality, and the mental attitude of the negro is such that treatment with arsenic is persisted in until the poisoning is well established. The negro has fragile veins of small caliber, thus accounting for the frequency of arsphenamine poisoning in the female sex. — GROESBECK WALSH and COURTNEY S STICKLEY *Am J Syphilis Neurology*, 19 (1935), 323, No 3, through *Squibb Abstract Bull*, 8 (1935), A-1175

Bismuth Poisoning Pharmacodynamics and Toxicology of Bismuth A case of syphilis which had been treated by Bismuth cinchophen oil suspension (Bismophanol) showed a brownish green, 1-cm wide streak on the left leg corresponding to the course of the Vena saphena magna and being 38 cm in length. Experimental histological studies were then made and it was found that under pathological conditions there is an increased deposition of bismuth in diseased tissue, especially syphilitic granulation tissues. This substantiates similar finds of other observers. — H SAUFERLIN *Dermatol Wochschr*, 100 (1935), 585, No 21, through *Squibb Abstract Bull*, 8 (1935), A-877

Cosmetic Products—Dangers of The *Ciba Zeitschr* calls attention to the fatal accidents caused by the products in use in certain beauty salons. The dangers are increased when the application of certain dye products precede the removal of hair. The use of dimro phenol in the treatment of obesity is also extremely dangerous. — *J Suisse Pharm*, No 16 (1935), 198, through *J pharm Belg*, 17 (1935) 591 (S W G)

Cyanide Poisoning and Its Treatment A table of mortality statistics shows an increase in deaths from cyanide poisoning from 1930 to 1932. Cases are listed as suicidal, occupational, accidental and homicidal. A number of sources are given for occupational and accidental cases. In general over 90% are suicidal. In some places in the west, cyanogenetic plants are the cause of large losses among animals. Ten points are listed as aids to diagnosis. Five important tests for legal purposes, with reagents needed, procedure and interpretation of results, are given. The antidote consists chiefly of sodium nitrite and sodium thiosulphate injected intravenously, with amyl nitrite by inhalation. — K K CHEN, CHARLES L ROSE and G H A CLOWES *J Am Pharm Assoc*, 24 (1935), 625 (Z M C)

Gold Therapy—Agranulocytosis with Purpura Hæmorrhagica Following A fatal case of purpura hæmorrhagica with agranulocytosis following gold injections is reported. The prophylaxis and treatment of such cases is discussed. The necessity for frequent hæmatological studies is emphasized. — P ELLMAN and J S LAWRENCE *Brit Med J*, 3900 (1935), 622 (W H H)

Gold Therapy—Prevention and Treatment of Harmful Effects of The harmful effects and contraindications of gold therapy are discussed, fever, pregnancy, advanced tuberculosis, chancres, diabetes, liver or kidney damage, advanced age changes in the urine, leucocytes, eosinophils (indications of cutaneous erythema) and general symptoms deserve consideration. Therapeutic agents are intravenous injections of sodium thiosulphate, hypertonic dextrose transfusion, pentosenucleotide (in agranulocytosis) and diuretics.—G PIOTROWSKI *Wien med Wochschr* (1935), No 21, through *Squibb Abstract Bull*, 8 (1935), A 889

Hydrocyanic Acid—Antidotes of, and More Particularly the Mechanism of the Antidote Action of Glutathione In experiments on guinea pigs where 1.25 mg hydrocyanic acid per kilo body weight was shown upon injection to be the minimum fatal dose, injection of glutathione in at least half the equimolecular quantity of hydrocyanic acid at the moment of the crisis (asphyxic coma) caused violent tremblings, resumption of breathing and ready recovery. When 2.00 mg hydrocyanic acid per kilo was injected, the toxic action was too rapid to be overcome by glutathione. The antitoxic action of glutathione is not caused by a chemical change of hydrocyanic acid into innocuous thiocyanate compounds for which glutathione is to supply the sulphur, because in animals that survived by means of glutathione, then were killed and examined, hydrocyanic acid was practically absent in the viscera and nontoxic thiocyanate compounds were present in about the same quantity as in parallel cases where hydrocyanic acid was applied without the use of glutathione; hence, sulpho compounds are not chemical antidotes. The action of glutathione at the critical moment of injection starts resumption of breathing sufficiently long to allow elimination of the poison through the lungs. If glutathione is administered in reduced form it is the partial re-oxidation and re-establishment of equilibrium between the two forms of glutathione within the circulation which produces shock, i.e., tremblings, spontaneous resumption of breathing and recovery. Other poisonings, i.e., those that act on tissue respiration, can probably be overcome by glutathione.—M TH REGNIER *11me Congrès de Chimie Industrielle Paris* (Oct 1934) 11 pp (A P C)

Hypnotic Poisoning, Acute—Treatment of Poisoning by hypnotics, particularly the barbituric acid derivatives, is discussed. Therapeutic measures consist of washing the stomach during the first 8 hrs with animal charcoal and sugar lime, N N diethyl nicotinamide (Coramine), camphor which is indicated as a cortical analeptic in convulsions, large doses of strychnine intravenously to antagonize the barbiturates, oxygen, infusions with epinephrine and insulin. Hydroxy α (methylaminomethyl) benzyl alcohol (sympatol) and synthetic ephedrine (ephedronne) often fail.—HANS FISCHER *Schweiz med Wochschr* (1935) Nos 20-21, through *Squibb Abstract Bull*, 8 (1935), A-1375

Pyrethrins—Comparative Toxicity of, with Respect to Different Classes of Animals Pyrethrin emulsions of known concentration were injected into the general cavity of various animals and the average minimum lethal dose determined in mg per Kg. The following were used as test animals: Polypes, sea anemone, Echinodermes sea urchin and starfish, Crustaceans, crab, sea spider, crawfish, scorpion, Insects, *Blaps requei*, Worms, earth worm, sand worm, leech, Mollusks, oyster, snail and cuttle fish, Cold blooded Vertebrates, frog, green lizard, snake, tortoise, Warm blooded Vertebrates, rat and guinea pig. Pyrethrins showed a special toxicity toward the crustaceans, they being killed by 1/100 to 1/150 mg per Kg. Toward the other classes of animals the toxicity was variable.—OLIVIER GAUDIN *Compt rend* 201 (1935), 356 (G W H)

Sabina—Two Cases of Intoxication by The tops of *Juniperus sabina* L., when taken orally in large doses, sometimes produce abortion followed by fairly serious poisoning. Two fatal cases of such poisoning are discussed, in both of which death occurred without abortion having taken place. The oil of sabina is fixed in the lungs, liver, uterus and kidneys, especially in the lungs and kidneys. Analysis of an aborted foetus showed the presence of oil of sabina in the viscera, which proves the permeability of the placenta to the drug, and which can be valuable for proving abortion in non fatal cases. Preservation of the viscera in formalin reduces the sensitivity of the test from 0.1 Gm to 0.5 Gm, and prevents a positive reaction with alcoholic hydrochloric acid.—MARIE J PAPAVALSIOU *Ann Med Legale Criminol Police Sci*, 15 (1935), 778-781 (A P-C)

Sodium Formaldehyde Sulfoxylate—Value of, in Mercury Poisoning The authors review the work previously reported on the use of sodium formaldehyde sulfoxylate (I)

in mercurial poisoning I is a powerful reducing agent and is more stable in the body than sodium thiosulphate and sodium hydrosulphite. Owing to its low toxicity as much as 10-15 Gm may be given intravenously in 10% solution, 5-10% as gastric lavage leaving 100-200 cc in the stomach and a 5% solution by enema. Treatment is repeated in severe, acute cases within 4-6 hours and again in 24 hrs. In 1 case reported, treatment consisted of 6 intravenous injections of I over a period of 4 days. In the second case following a large amount of calomel, intravenous injection of I during 4 days was followed by complete recovery. In both of the reported cases, the poisoning was not severe, so that intravenous treatment alone was used. In cases of severe poisoning with mercuric chloride, intravenous injection should be accompanied by oral use and enemas to avoid tissue destruction.—WM E ROBERTSON and VERNON L TUCK *J Chemotherapy*, 12 (1935), 226, No 2, cf *S A B*, 7 (1934), 633, through *Squibb Abstract Bull*, 8 (1935), A-1189

Sodium Perborate Preparations—Harmful Effects of Sodium perborate preparations when used as a mouthwash or dentifrice occasionally produce escharotic effects on the oral mucosa characteristic of chemical burns. This may occur as an idiosyncrasy to the drug, or more likely may be due to sodium hydroxide impurities or the strong essential oil flavorings in the preparation. Two cases are reported in which the symptoms were a burning sensation of the mucous membrane of the mouth which was found to show inflammation and moderate cyanosis, sloughing epithelium on the inner surfaces of the lips, cheeks and buccal folds, thickened cheeks, swollen dry lips, swollen tongue and in one case a typical brown hairy tongue. When a mild saline mouthwash was substituted the symptoms disappeared in 3-4 days. Pin head ulcers seen on the alveolar mucosa or cemental gingiva in the above cases are more frequent when the preparation is used on the tooth brush as a dentifrice, suggesting a traumatic effect of the sharp crystals of the powder.—CHARLES H M WILLIAMS *J Canadian Dental Assoc*, 1 (1935), 267, No 6, through *Squibb Abstract Bull*, 8 (1935) A-906

Toxin X. The author designates as "Toxin X" poisons occurring in whole grain cereals—tea, coffee, cocoa, fruits and certain vegetables picked before maturity, beers and ales, malt extract, yeast, honey, brown sugar, nuts and olive oil. These toxic substances in foodstuffs can be detected by the physiological effects produced by the consumption of liberal quantities of the specified foods over a period which may vary from a few days to a few weeks. The effects referred to are (1) The production of bilious conditions, (2) inflammation of mucous membranes, (3) predisposition of ordinary body tissue to sensitive and painful conditions, (4) marked interference with normal digestive, assimilative and excretory process. "Toxin X" is described as both a tissue poison and an astringent. A diet free from the toxin-bearing foods gives absolute immunity from the disorders.—C W GREEN *J Soc Chem Ind*, 54 (1935), 717 (E G V)

Tribromethanol Anesthesia Solid tribromethanol, used as a general anesthetic, has proved decidedly dangerous. The chief danger from the use of this preparation is respiratory depression, but so far no death has been caused by tribromethanol in amylene hydrate, nor have there been any fatalities from post-operative pulmonary complications.—F SHIPWAY *Clinic Med and Surg*, 42 (1935), 434 (W H H)

Venoms of North American Pit Vipers—Studies on The danger to man from the bites of pit vipers, varies almost directly with the size of the species. The larger species of viper gave the largest number of fatal doses per extraction. The more primitive forms have venoms more toxic to the nerve centers.—T S GITHENS *J Immunol*, 29 (1935), 173 (A H B)

THERAPEUTICS

Adrenaline—Inhalation of, for the Relief of Asthma Using an atomizer which creates a fine vapor-like spray, a 1:100 solution of adrenaline is inhaled while nebulizing the solution into the open mouth. Dosage is determined by the number of inhalations and varies with each individual. For administration to children and babies a motor driven air pump is used to create a continuous spray into a small face mask. The degree of relief obtained by this method is comparable to that resulting from the hypodermic administration of the 1:1000 solution.—J B GRAESER and A H ROWE *Calif and West Med*, 43 (1935), 110 (W H H)

Allergy A general discussion of common allergies, with emphasis on cosmetics.—HERMAN GOODMAN *Am Perfumer*, 31 (1935), 97-100 (G W F)

Anti-Malarial Drugs of Natural Origin The only anti-malarial drugs generally accepted as such are the cinchona alkaloids and the new dialkylaminoalkylaminoquinolines and acridines

Tests in bird malaria were used in an attempt to settle a long outstanding controversy, viz that of the relative, anti malarial efficiency of the various cinchona alkaloids, of which there are eight—quinine, quinidine, cinchonidine, cinchonine, each being accompanied by its dihydro derivatives. The results show they may be arranged in the following descending order of activity

	Quinine Equivalent
Dihydroquinine	1 to 2
Quinine	1
Dihydroquinidine	0.5 to 1.0
Cinchonidine	About 0.5
Quinidine	About 0.5
Cinchonine	Less than 0.2
Dihydrocinchonine	Less than 0.2
Dihydrocinchonidine	Less than 0.2

These results are of interest as supporting the general view that quinine is the most active of the common cinchona alkaloids. Certain derivatives of plasmoquine in which variations had been made in the type of side chain attached to the N of the amino group were promising. One of them corresponding to the formula

had given good results in bird malaria and was worthy of further trial. A brief account of the history of plasmoquine (1924) and atebrin (1930) was also given.—T. A. HENRY, R. ROBINSON and W. SCHULEMANN *Pharm J*, 135 (1935), 276 (W. B. B.)

Antimony Content in Drugs—Consideration of the, Used for Destruction of Schistosomes
The antimony content, therapeutic dose and value and in some cases the tolerated dose and stability have been given for the following: antimony potassium and antimony sodium tartrates, N glucoside of sodium *p* stibanilate (neostam), sodium and potassium antimony pyrocatecholdi sulphonates (fuadin and antimosan, respectively) and the corresponding calcium salt, which is of service in skin conditions for which antimony is used but has no greater value than the other salts in the destruction of schistosomes, antimony *bis* hydroxyquinoline sulphonate diethylamine (stibilase, Dn 7), antimony methylene bisulphite amino hydroxyquinoline sodium sulphonate (try stibine, Dn 18), acetyl *p* phenylenediamine antimony tartrate, and *p* phenylene diamine antimony tartrate.—F. GORDON CAWSTON *J Trop Med Hyg* 38 (1935) 169 No 14, through *Squibb Abstract Bull*, 8 (1935), A-1151.

Athlete's Foot Three definite forms occur: (1) vesicular, which may appear suddenly on any part of the foot usually between the toes and under the instep, and is characterized by itchy patches of dermatitis; (2) intertriginous, more severe, often painful and intensely itchy, developing between the toes as a white sodden mass of broken skin; and (3) chronic, which may appear on the hands and is identified by hardening of the skin on the infected area. The following formulas are offered: (1) *Lotion*—Sodium thiosulphate 10% water 90; (2) *Dusting Powder*—Sodium thiosulphate 20%, boric acid 80; (3) *Lotion*—Mercury perchloride 0.3%, carbolic acid acetic acid (glacial) 8, water 89.7; (4) *Paint*—Potassium permanganate 5% water 95; (5) *Ointment*—Ammoniated mercury 5%, salicylic acid 10, white petrolatum 85; (6) Phenol 2%, benzoic acid 3.5, boric acid 5.5, cold cream 89.—ANON *Drug and Cosmetic Ind*, 37 (1935), 180 192 (H. M. B.)

Avertin Anesthesia—Treatment of Tetanus with A case of severe tetanus neonatorum with recovery is described. Treatment consisted of one large initial dose of intravenous avertin followed by continuous anesthesia with avertin for eleven days and smaller doses for a further twelve days. Nasal oxygen was given continuously for long periods and a normal diet by stomach tube which was left *in situ*. A total of 19.2 cc. of avertin was given in the first eleven days and 22.4

cc altogether in twenty three days It is suggested that treatment on the above lines with large and frequent doses of avertin will prove of great value in the treatment of severe cases of tetanus The need for caution in giving such large doses is emphasized —L COLE *Lancet*, 229 (1935), 246 (W H H)

Azo Dyes—Sulphide Analogues of, Having Bactericidal Properties The present report is a continuation of studies previously reported The compounds prepared are of two types One combined the diaryl sulphide linkage with the *p* ethoxy benzene azo residue of serenium Two combined the diaryl sulphide linkage with the diaminopyridine grouping of pyridium 4, 4'-*Bis* (α, α diaminopyridine azo) diphenyl sulphide and 3, 5 *bis* (4'-amino diphenyl sulphide azo) 2, 6 diaminopyridine They were found to be only slightly soluble in media in which they might be used and they were inactive Details of experimental work are reported and structural formulas of the compounds prepared are given —W BRAKER and W G CHRISTIANSEN *J Am Pharm Assoc*, 24 (1935), 607 (Z M C)

Azochloramid—Use of, in Root Canal Antisepsis Like other chlorine compounds, but unlike all other antiseptics, azochloramid is not markedly group specific, destroying most types of micro organisms In a comparison with other chlorine compounds, namely, chlorinated soda and chloramine-T, a solution of chlorinated soda dropped to 10% and chloramine-T to 50% after four hours, while even after 24 hours most of the azochloramid originally added was still active A quick test for the presence of otherwise invisible quantities of azochloramid is the acidulated starch-iodide test The material to be tested is brought in contact with a small quantity of potassium iodide solution, acidulated with acetic acid or hydrochloric acid and containing a small amount of starch solution The presence of azochloramid causes this solution to assume a blue to black hue owing to the formation of free iodine This test was used as an indicator to trace the degree of penetration of the compound through pulpless teeth Teeth, freshly removed in pyorrhea cases, were opened in the crown and the pulp was removed, the canal cleared and the tooth set in a small block of cement The root canal was filled with an azochloramid dressing, just as if the tooth were still under treatment in the patient's mouth After a day or two test borings were made and small drops of the test solution placed in contact with the dentin In most cases the dark color appeared in 24 hours, showing that penetration of the dentin was accomplished In a series of 63 consecutive cases treated, successful application of azochloramid in treatment was made —H J ROSS *J Am Dent Assoc*, 22 (1935), 637 (T G W)

Bedsore—Treatment of If the skin is rough and excessively dry the following ointment should be rubbed in after the back has been washed with hot water zinc stearate, 5, tincture benzoin, 5, scarlet red ointment 5%, 0.25, hydrous wool fat, 30, liniment of camphor, 180, mutton tallow, 500 For hardening the skin a 5% solution of silver nitrate may be painted on Moist treatment is only indicated in cases of spreading infection or of retained pus Warm borie acid compresses are used and irrigations of solution of chlorinated soda —ANON *Pharm J*, 134 (1935), 565 (W B B)

Calciferol—Treatment of Low-Calcium Tetany with The progress of three cases of low-calcium therapy, treated with calciferol, is described It has been found possible to maintain the patients free from symptoms with normal blood findings Possible toxic effects are discussed —R S STACEY *Lancet*, 229 (1935), 656 (W H H)

Castor Oil—Newer Uses of Castor oil is of the greatest value in gastroduodenal catarrh, colitis and the so called irritable colon In the toxemias associated with chronic constipation and malignant disease, it will be found of greatest assistance Its detoxicating effect on the products of tissue destruction in burns is of more than passing significance In urinary sepsis, as found associated with chronic inflammatory urinary conditions—pyelitis, prostatic hypertrophy, chronic prostatitis and new growths—all other pharmaceuticals used to produce evacuation must give way to castor oil The author claims that salines are dangerous, and therefore are to be avoided in urinary disease —W, S PUGH *Clin Med Surg*, 42 (1935), 324 (W H H)

Chaparro Amargoso—Use of, in Treatment of Amebic Dysentery A literature review is given of the therapeutic use in amebic dysentery of *Chaparro amargoso* (*Castela Nicholsonii*) or bitter bush, a shrub growing in Mexico and Texas The active principle is available under the name Castamaragina In the discussion following the paper Blake describes his experience with the drug It gave excellent results in cases that did not tolerate arsenicals On the other hand, the drug was not tolerated by some two cases showing typical severe allergy Lindley uses the

drug for all kinds of intestinal disorder with excellent results, but Blake found that in amebic dysentery of the upper intestinal type, the best results are obtained with arsenicals such as N carbamyl arsanilic acid (carbarsone) and that emetine is the only drug to be depended on where there is liver involvement —G W VAN HALTERN *J Am Coll Proctology*, 7 (1935), 402, through *Squibb Abstr Bull*, 8 (1935), A 921

Chemotherapeutic Research—Some Lines of A brief survey of some of the lines in which chemotherapeutical research is developing including a discussion of some arsenicals, bismuthals and antiseptics —F L PYMAN *J Soc Chem Ind*, 54 (1935) 580 (E G V)

Cinchophen (Atophan) Therapy and the Liver The action of cinchophen consists in mobilization of uric acid, desinflammation and in stimulation of hepatic secretion The bile secretion may be increased by 300% after 2-3 daily doses of one Gm orally The parenteral dose is 0.5 to one Gm The results in hepatic icterus are very favorable The diet in such cases should be rich in carbohydrates This precaution prevents any damage to the liver B believes, that most cases of cirrhosis after cinchophen treatment would have developed as well without the use of the drug —THLONOR BRUGSCH *Semana med* (Buenos Aires), 42 (1935), 1907

(A E M)

Cod Liver Oil Concentrate—Retention of Calcium by Infants Fed Evaporated Milk Containing Milk containing cod liver oil concentrate sufficient to allow 400 U S P units of vitamin D to the reconstituted quart, allows high retention of calcium, prevents the development of rickets and permits excellent development and growth of infants —P C JEANS and GENEVIEVE STEARNS *Proc Soc Exptl Biol Med* 32 (1935), 1464 (A E M)

Cod Liver Oil Treatment of Wounds When crude cod liver oil is used for the treatment of second and third degree burns there is a complete healing of the wound without the trace of a scar or the usual brown pigmentation of the skin If *Staph pyogenes aureus* is inoculated into cod liver oil and incubated for forty eight hours it will be found that the bacteria are still alive but their growth inhibited Whether the vitamin content in cod liver oil has a natural affinity for the skin and the underlying tissues it is difficult to say, but there is obviously some factor in cod liver oil which is not present in such oily dressings as liquid paraffin This "something" has the effect of much more rapid healing and the almost entire elimination of scar tissue —J P STEEL *Lancet*, 229 (1935), 290 (W H H)

Colloidal Gold in Inoperable Cancer In order to secure maximum results with colloidal gold in the treatment of inoperable carcinoma, the following conditions must be fulfilled The preparation used must be stable, of definitely known strength and the particles of gold must be small and of fairly uniform size, the gold must not be held in suspension by the use of a stabilizer such as gum arabic or soluble gold salts such as chloride of gold Stabilizers seem to coat the particles of gold and thus renders colloidal gold less active, moreover the soluble gold salts are toxic, while pure colloidal gold is non-toxic in suitable doses A colloidal gold preparation which fulfilled the foregoing requirements and which contained $1/100$ grain of metallic gold to ten drops was employed The dose used was 30 drops in a wineglass of water one half hour before each meal, three times a day This was increased one drop daily to 60 drops at each dose The intra venous dose was 1 to 5 cc, twice a week —E H OCHSNER *Clin Med Surg*, 42 (1935), 321

(W H H)

Cyclopropane Anesthesia in Obstetrics Cyclopropane is an efficient anesthetic producing analgesia for each pain, following one or two inhalations It is also powerful enough to produce complete anesthesia, even when given with a high percentage of oxygen Neither the mother nor the child is in any danger of asphyxiation with this anesthetic The uterine contractions are not interfered with, and such anesthesia does not cause vasomotor shock though it produces complete relaxation of the voluntary muscles —R T KNIGHT *Clinic Med and Surg*, 42 (1935) 433

(W H H)

Dermatitis—Preparations for The following formulas are offered (1) Propyl p amino-benzoate 3%, butyl stearate 4, alcohol 7, beta naphthol 2.5, cetyl alcohol 2, olive oil 3 water 65.5 glyceryl monostearate 4, ether 9 Boil the glyceryl ester oil, cetyl alcohol, butyl ester and water Mix until the temperature drops to 30° C Dissolve the betanaphthol in alcohol, add the propyl derivative in ether and stir in, (2) Picric acid 0.5%, alcohol 7.5, water 92 Dissolve the acid in the alcohol and add to the water To make anesthetic add 5-6% of the compound, (3) *Soothing Lotion* —Salicylic acid 1.0%, menthol 0.3, rose water 95.7, alcohol 3 Dissolve the menthol in

the alcohol and the acid in the water and mix (4) Calamine 6 %, zinc oxide 2, lime water 91, camphor 0.5, phenol 0.5 Mix the camphor and phenol and allow to stand until liquefied, sift the oxide and calamine into the lime water with constant agitation and add the above mixture (5) *Antiseptic Ointment*—Ammoniated mercury 5%, boric acid 4, zinc oxide 10, oil of cade 0.5, soft white petrolatum 80.5 Melt the petrolatum, stir in the rest of the substances, cool and pass through an ointment mill (6) *Anæsthetic Oil*—Propyl *p* aminobenzoate 5%, oxyquinoline benzoate 0.2, refined sesame oil 94.3, oil of cade 0.5 Heat and mix the oils and dissolve the first two ingredients—ANON *Drug and Cosmetic Ind.*, 37 (1935), 318, 326 (H M B)

Drugs—Constitution and Action of The chemical structure of the anti syphilitic arsenicals has changed little in the last twenty years Then, as now, 3 amino-4 hydroxyarsenobenzenes were the most effective remedies Certain simpler 3 amino-4-hydroxyphenyl derivatives of arsenic have recently found favor, principally Halarsol and Mapharsen In dysentery, on the other hand pentavalent arsenicals and not trivalent, are required and compounds of the type of Tryp-

arsamide and its lower homologue, Carbarsone are employed Oil-soluble bismuth salts form deposits which are slowly absorbed, yet not so slowly as the metal itself In neurosyphilis, sodium iodobismuthate, $\text{Na} \cdot \text{BiI}_4$, dissolved in glycol is injected, and in this case the bismuth is in the anion Morgenoth in 1911, was able to show in some simple derivatives of hydroquinone that in ascending an homologous series distinct peaks of maximum antiseptic activity against different organisms were obtained As a result he produced Optochin, Eucapin and Vuzin, respectively, the ethyl, iso amyl, and iso octyl derivatives of hydrocupreine The recent work of Barger and Robinson has shown that whereas the natural alkaloid harmine,

is inactive, yet the corresponding alcohol harmol, etherified with butyl, amyl and nonyl groups yields peaks of activity against *B. typhosus*, *Staphylococcus aureus* and *Entamoeba histolytica*, respectively Two urinary antiseptics of recent introduction are azo-pyridines

Pyridium

Neotropin

F L PYMAN *Pharm J.*, 134 (1935), 619

(W B B)

Enteric Coatings—Comparative Study of Previous study had shown a wide variation in efficiency of coating materials Through the coöperation of several manufacturers their enteric coatings on tablets of barium sulphate were studied Five different coatings were submitted, two of keratin, one salol shellac, one shellac and a mixture of salol and resins In every case they resembled any sugar coated tablet Subjects for the experiments were normal individuals in apparent good health The X-ray was used to determine exact point of disintegration Subjects were given tablets followed at once with glass of water containing a teaspoonful of Bari O-Meal The first radio graph was taken in thirty minutes and afterward at intervals Results are tabulated according to type of coating, and tabulation shows number of tablets taken time taken and point and time of disintegration The data show about as much variation in the commercial coatings as in those prepared in the laboratory Keratin coating No 1 was completely disintegrated in the stomach in about one hour Keratin coating No 2 showed 13 tablets disintegrated in the colon, four in the small intestine and one in the stomach Point of disintegration

for seven was unknown and three were excreted. This coating then was 80.95% efficient. Shellac coating was shown to have no value for enteric medication. The salol resin mixture showed that 13 tablets disintegrated in the stomach and 22 in the intestines. Five had not disintegrated when the last picture was taken. This coating was 63.00% efficient. The salol shellac coating showed that eight tablets disintegrated in the small intestine and four in the stomach. Four capsules disintegrated in the small intestine and five in the stomach. The fate of three was not determined. Average time was 6 hours for tablets and four for capsules, percentage of efficiency being 66.66 and 14.44, respectively. None of the coatings studied was perfect. Best results seem to result with keratin properly applied. Considering absorption rate of colon less than small intestine salol mixtures seem best. Capsules are not as efficient as tablets because of mechanical difficulties.—F S BUKER and PHYLIS RHODIS. *J Am Pharm Assoc*, 24 (1935), 567.

(Z M C)

Ergot—Alkaloids of Ergometrine. The author recommends that ergometrine, when given for post partum hemorrhage, should be given in the following doses: by the mouth 1.0 mg, intramuscularly 0.5 mg, intravenously 0.125 mg. Fifty per cent increases above these doses have been administered without any untoward effect. As regards the clinical uses of the ergot alkaloids, the ergotoxine group is useful when a longer duration of uterine spasm is required. Ergometrine has the valuable properties of ergotoxine, but with special advantages in its remarkably quick action, particularly in the treatment of post partum hemorrhage. Ergometrine is a possible alternative to pituitary post partum, given intravenously it has actually quicker effect than an intramuscular dose of pituitary.—C MOIR. *Pharm J* 134 (1935), 63. (W B B)

Ergotamine Tartrate (Gynergene) Ointment—Use of, in Ano-Vulvar Pruritus. The formula used was benzoated fat and lanolin of each, 12 Gm. solution of ergotamine tartrate 0.1% one cc. Cure was obtained in obstinate cases.—J C GONZÁLEZ PODESTÁ and ALBERTO TORDERA. *Semana Med (Buenos Aires)* 42 (1935), 122. (A E M)

Forapin—Use of, in Rheumatic Diseases. Rheumatic diseases are treated with Forapin, an ointment containing bee poison by means of Iontophoresis. To increase the absorption of the bee poison 0.3% histamine is added (Ointment of Forapin with histamine).—R SPENGLER and G PRINERT. *Deut Med Wochschr* 61 (1935), 962-963. (H R)

Gold Salts—Use of, in Treatment of Pulmonary Tuberculosis. The following conclusions are given. The action of gold salts in the treatment of pulmonary tuberculosis is far from being as complete as many physicians suppose it to be. This action is not specific. Their general and inconsiderate use often leads to serious results. They are not, however, devoid of some value, their use is justified in certain well defined cases and on condition that the dosage is prescribed with caution.—GEERAERD. *Buyssinghen Bruxelles Med* (June 30 1935) 953 through *J pharm Belg*, 17 (1935), 611. (S W G)

Gonococcus Vaccine—Use of, in Acute Gonorrhea. A vaccine treatment with simultaneous use of extended local rinsing was indicated for acute gonorrhea and shortened duration of illness. But this treatment was not indifferent and should be given first after the disappearance of the acute symptoms about the 9th-11th day of illness, injections being given every 3rd-5th day. Vaccine therapy during the acute symptoms makes the course of the gonorrhea worse.—MARIASSIN and BAJEWSKIJ SOWET. *WESTNIK VENEROL Dermatol* (1935) No 4 through *Dermatol Wochschr*, 101, No 30 (1935), 931, through *Squibb Abstract Bull* 8 (1935), A-1166.

Hematoporphyrine—Use of, as a Therapeutic Agent in Psychosis. The hydrochloride of hematoporphyrine (Photodyne) was used in 37 cases of depressive psychosis. The majority of the patients showed improvement though the psychosis itself was not influenced.—EDWARD A STRECKER, HAROLD P PALMER and FRANCIS G BRACELAND. *Semana Med (Buenos Aires)*, 42 (1935), 1534. (A E M)

Heroic Drugs—Maxima Doses of Galenical Preparations of. After giving the results of his study on several drugs, the author presents the following considerations. The pharmacist and doctor must know the maxima doses of the heroic drugs and the preparations made from them. A simpler dose relationship is advocated and the following is offered: 1. The strength in active principles of a tincture corresponds to one-tenth of the strength in active principles of the powdered drug. 2. The strength in active principles of the extract should be double that of the powder. The fixing of the strength of powdered heroic drugs at 0.5% in active principles is also urged. The

maxima doses of the eleven heroic drugs and their preparations are presented in a table (XIII) — ZUNZ *Bull Academie*, No 4 (1935), through *J pharm Belg*, 17 (1935), 553 (S W G)

Histidine Monohydrochloride—Value of, in the Treatment of Peptic Ulcer Over a period of four months, the histidine monohydrochloride (Irostitin) treatment has been applied to twenty six cases, twenty four of duodenal ulcer, one marginal ulcer and one gastric ulcer. Marked diminution of acidity almost to the point of anacidity occurred in one quarter of the cases. Pain is alleviated in comparatively short time. There is a definite gain in weight and patients are able to tolerate a liberal diet —H A RAFSKY *Med Record*, 142 (1935), 289 (W H H)

Insulin Treatment of Menorrhagia and Metrorrhagia The author summarizes the favorable results of others, and describes his own, from insulin treatment of excessive uterine bleeding. His best results were obtained in menorrhagia in young subjects, in whom not infrequently the intermenstrual interval could be increased from about two to four weeks, and the duration of bleeding reduced one half, and in continuous profuse bleedings of metropathia haemorrhagica of puberty. Functional bleedings in older subjects were less constantly responsive to insulin treatment. As a special feature of his treatment the author recommends "prophylactic," intermittent insulin injections, beginning five days before the date of expected menstruation, carried on until the delayed bleeding begins, and then suspended. The initial dose may begin with 10 units twice daily, increasing to 20 or 30 units, a low blood sugar level calls for smaller doses. Sugar and starches are given in considerable amounts. Simultaneous administration of ergot, which increases insulin sensitiveness, is contraindicated —E KLAFTEN *Zentralbl f Gynäk* (June 29, 1935) 1512, through *Brit Med J*, 3901 (1935), 710C (W H H)

Ipecac—Brief Study of The physiological action, indications and antidotes for ipecac, and the drugs which follow it well, are discussed. Its action is compared with that of antimony tartrate —H FARRINGTON *J Am Inst Homeopathy*, 28 (1935), 404, through *Squibb Abstr Bull* 8 (1935), A-1003

Lipiodol—Use of, as a Therapeutic Agent The value of lipiodol in diagnosis is now well recognized, but its beneficial effect on certain inflammatory conditions may not be generally appreciated. Two cases of localized chronic inflammatory meningitis are reported, both having a certain amount of paresis with loss of control of rectal and bladder sphincters. In both of them, lipiodol was injected into *cisterna magna* primarily for diagnostic purposes, and in both of them the symptoms were alleviated in an almost miraculous way, with complete cure later —G HARROWER *Lancet*, 229 (1935) 715 (W H H)

Lysates The designation lysate is derived from lysis which signifies dissolution or separation. Under this designation preparations are marketed derived from various animal organs by means of fermentative dissolution or by autoclaving. According to some authors lysates represent organotherapeutic preparations, the active principles of which are products of tissue decomposition of individual organs. Each lysate consists of a dynamic and a plastic fraction. The dynamic fraction is the specific and the active one. The plastic fraction is represented essentially by polypeptides and amino acids, its function is to assure nutrition. It has been shown experimentally that many lysates are actually specific, for instance, in rabbits lysates prepared from kidney tissue always produce a nephritis while lysates prepared from other organs have absolutely no influence on the kidneys. Myolysate given subcutaneously or internally was found very useful in the treatment of various cardiac affections especially *Angina pectoris*. Testolysate, a lysate derived from testicular tissue is widely employed in the treatment of sexual neurasthenia. Ovario-lysate a lysate derived from ovarian tissue has been successfully employed in the treatment of infantilism, incomplete development of the secondary sexual traits, hypoplasia of the female genital organs, oligomenorrhea, dysmenorrhea, amenorrhea and polymenorrhea. It has also been successfully employed in the treatment of some abnormalities associated with pregnancy —A RABINOVITSCH *Soviets Pharm*, 2 (1935), 21 (A S)

Malaria—Chemotherapy of In Germany two synthetic anti malarials—plasmoquine and atabrin, have been prepared. The most important defect of quinine as an anti-malarial is its failure to prevent infection. In an investigation with quinine, atabrin and plasmoquine against infections of malignant tertian malaria all the controls who took no prophylactic drug and all those who took quinine as a prophylactic had their attack of malignant tertian malaria within the usual incubation period, but none of those who took atabrin or plasmoquine had any malarial attack. Other defects of quinine are (a) it is not equally effective against all species and strains

oxidation of ascorbic acid designated ferriscorbone (II) (I) and (II) were tested on experimental cancers of the rabbit's testicle Both caused perilesional edemas that were successfully reabsorbed by allylthiocobromine given intravenously (II) was less active and also caused less intense edemas Fifty % of the cases were cured and generally the cancerous condition was retarded Both products were tried clinically on some grave cases of human cancer that were either inoperable or not benefited by radiotherapy Three cases of cancer of the tongue have been successfully treated with (I), being injected intravenously several times daily for six months Indications and contraindications are given This technique is not to be viewed as an indication of a possible prophylaxis or preventive of cancer The mechanism of the reaction is the stimulation of the fermentation processes resulting from the reversible systems of oxidation and reduction—FERNAND ORLOING, ALBERT MORI L and ANDRE JOSSERAND *Compt rend*, 201 (1935), 456

(G W H)

Sphagnum and Its Therapeutic Use 1 Sphagnum should be employed as material for dressing It is easily obtainable in Russia and its resources are inexhaustible 2 It possesses hygroscopic and capillary properties and when sterilized it can be applied directly to the wound just as sterile cotton 3 It should be moistened somewhat before use since when dry its adsorbing properties are decreased considerably 4 Sphagnum may also be employed as a splint padding because it is light soft and elastic 5 It may also be used for filling mattresses and cushions for children 6 It is best packed for shipping in packages of 10-20 Kg after it has been compressed For shipping to distant places it should be packed in larger bales The quality of sphagnum should be controlled by analytical studies in the laboratories or pharmaceutical dispensaries—F I IVANOV *Soviets Pharm* 2 (1935) 9

(A S)

Staphylococcal Affections—Specific Treatment of The authors have employed a staphylococcal anatoxin with marked success in certain staphylococcal infections (furunculosis acne abscess, etc) This anatoxin, prepared similarly to diphtheritic anatoxin is non toxic, and possesses an intrinsic antigenic property with the production of a specific antitoxin and immunity It should possess a high antigenic power and be administered in sufficient doses The authors usually give, at intervals of five days, three successive subcutaneous injections of 0.5, 1 and 2 cc of undiluted anatoxin Patients tolerate this treatment well a slight transient fever may occur some hours after the injections, but focal reactions are rare—G RAMON *et al Presse Med* (July 17, 1935), 1137 through *Brit Med J* 3901 (1935) 710B

(W H H)

Sulphurated Oil As sulphurated oil Loeper and his collaborators have used mainly the following formula Flowers of sulphur 0.5 (1.0 Gm) and oil of sesame 100 cc Solution occurs slowly on a boiling water-bath and the product is stable Each cc contains 0.005 mg (or 0.01 cg) of flowers of sulphur The intramuscular injections in chronic rheumatism are 2 cc every two or three days Although the injections are painful and they raise the temperature of the patient to 39° or even 40° the results are interesting suppleness increasing mobility becoming greater, and, after some time diminution of the pain to a point permitting the suppression of sedatives On the other hand, Michaux and Mollaret have injected the sulphurated oil of sesame into paralytcs, and here also improvements have been noted—UNION PHARMAC (July 1935), 194 through *J pharm Belg*, 17 (1935) 670

(S W G)

Suprarenal Gland—Treatment of Whooping-Cough with O Balfour (*Arch Pediat* (March 1935), 143) has treated 192 cases of whooping cough with desiccated whole suprarenal gland Fifty six required no further treatment, thirty eight were given thyroid, fifty eight non specific proteins forty pertussis vaccines in addition when the suprarenal substance alone did not control the cough He recommends whole suprarenal gland The results obtained with non specific proteins and commercial vaccines were equally good and superior to those following thyroid gland—*Brit Med J*, 1 (1935), 48C

(W H H)

Tannic and Picric Acid in Burns Modern treatment of burns embraces the following (1) relief of pain (2) protection of the denuded areas (3) application of antiseptics to prevent or combat infection, (4) promotion of healing and repair, (5) combating the shock and fluid deprivation (6) prevention and treatment of toxemia, (7) prevention of contractures and (8) replacement of tissue by grafting The least troublesome and most comfortable wet dressing for burns of a limited degree and area is a 1% solution of picric acid because of its protective, antiseptic astringent and analgesic properties, it stimulates the reproduction of epithelium its stains are readily removed by applying powdered potassium sulphate for a minute and then washing with soap

or by a paste of magnesium carbonate. The use of a stronger solution increases the danger of poisoning. Tannic acid also has the above properties, brings about the coagulation of devitalized tissue for burned area and by the formation of a tanned crust protects the surface and relieves pain. B offers the following formula for an ointment for mild burns of limited area: Tannic acid 5%, picric acid 0.5%, benzocaine 2% and ointment base. A cooling effect may be obtained by the addition of menthol and increased thickness by adding zinc oxide or starch.—R. RICHARD BLISS, JR. *Drug and Cosmetic Ind.*, 37 (1935), 177, 184 (H. M. B.)

Termopsis—Use of, as an Expectorant. Recent studies have shown that *Termopsis lanceolata* can be used as an expectorant. This plant has been used empirically by the laity for the treatment of influenza, bronchitis, pneumonia, etc. From the plant proper and from the seeds of termopsis two alkaloids have been obtained: termopsine which is easily crystallized and a liquid termopsidine. The former alkaloid is chemically analogous to other active principles found in various plants belonging to the family leguminosa, for instance, lupanine, metrine, retamine, etc. Experimental studies carried out on frogs, mice, rats, rabbits, cats and dogs have shown that the infusions and extracts obtained from the termopsis plant, as well as the crystalline products obtained from this plant, act chiefly on the medulla oblongata and cerebrum, especially on the respiratory, vaso motor and vomiting centers. Depending on the dose this action is either tonic or stimulating, or depressing and paralyzing. The vomiting observed in cats and dogs is not only of a central, but also of a peripheral origin, that is, it acts not only on the vomiting center directly, but reflexly on the mucosa of the stomach. The direct and reflex action of small doses of termopsis on the vomiting center leads to an increased secretion of the mucosa of the respiratory tract, and acts as an expectorant. On the basis of the studies outlined above one may recommend this substance as a good expectorant and best results are obtained from an infusion given in doses of one tablespoon three times a day.—N. V. VERSHININ. *Soviets Pharm.*, 4 (1935), 29-31 (A. S.)

Thiobarbiturates. A series of thiobarbiturates has been prepared by condensing derivatives of malonic ester with thiourea. Previous work had shown that the administration of 120 mg./Kg. of the sulphur analogue of 5,5-dithiyl barbituric acid (barbital) to dogs produced sleep followed by death. The authors studied a number of thiobarbiturates and found that they showed promise as sedatives. They produced quiet, natural sleep and were free from side actions and from the after-effects observed following the use of their oxygen analogues. The work is being continued and will be reported in detail.—ELLIS MILLER, JAMES C. MUNCH and FRANK S. CROSSLEY. *Science*, 81 (1935), 615, No. 2112, through *Squibb Abstracts Bull.* 8 (1935), A-876.

Thyrotoxicosis—Action of Iodine in. The role of iodine in the physiology of the thyroids is discussed from theoretical aspects. A study of approximately 575 clinical cases of thyrotoxicosis showed that the administration of iodine to thyrotoxic patients produced a characteristic and specific response which consisted of an amelioration of symptoms and a decline in metabolic rate, and that this response to iodine therapy would occur at any stage of the disease. It appeared, however, that the response had no relation to the duration or direction of progress of the disease, but merely acted as a check on the intensity of its symptoms. These clinical facts were concluded to be consistent with the theory that in thyrotoxicosis the thyroid allows the escape of thyroxine to proceed at an excessive rate, and that the cells of the thyroid hyperfunctioned in consequence. It was suggested that iodine sets up a temporary obstacle to this excessive outflow by checking the leakage of thyroxine from the gland. The authors believe that so-called refractoriness is apparent, not real, that thyrotoxic patients who are unaffected by iodine are those who are already fully iodimized. They believe that iodine response is valuable in the management of toxic goiter, both in treatment and in diagnosis, but its fundamental nature must be familiar if it is to be used successfully. The type of iodine preparation administered is unimportant.—J. H. MEANS and JACOB LERMAN. *J. Am. Med. Assoc.*, 104 (1935), 969 (M. R. THOMPSON).

Trichophytosis. This form of dermatoses—also "Epidermophytosis"—is commonly known as Athlete's Foot, Gym Itch, Athlete's Foot Itch, Jockey Strap Itch, Ringworm of the Foot, Dhobie Itch, etc., is caused by a parasitic fungi and occurs in several forms: (1) *vesicular*, characterized by the formation of little blisters, (2) *scaling*, both occurring on the toes, soles, fingers and palms, (3) *macular*. (a) "*Eczema marginatum*" or "Jockey Strap Itch" red definitely margined lesions in the groin region, axillae and beneath the breasts and (b) "*Tinea circinata*," slightly elevated, ring-like patches on neck, face and hands referred to as ringworm on the body, (4) *macerated*, lesions between the toes as an area of clean white sodden tissue of varying degree.

of thickness The following dermat therapeutic agents are listed in order of their descending irritant action chrysarobin, pyrogallol, mercury bichloride, ammoniated mercury, mercurial ointment, iodine, tar, phenol, ichthyol, sulphur, resorcinol, chlorothymol, salicylic acid benzoic acid and boric acid The following formulas are offered (1) *Deek's Salicylic acid* 8%, ammoniated mercury 4, bismuth subnitrate 12 oil eucalyptus 12 hydrous wool fat 64 (2) *salicylic acid* 5% *benzoic acid* 5, chlorothymol 2, propyl *p* aminobenzoate 5% or benzocaine 10%, vanishing cream base, (3) *Prophylatic Powder*—Powdered sodium thiosulphate 20%, powdered boric acid 50, purified talc (sterilized) 30%—A RICHARD BLISS JR *Drug and Cosmetic Ind*, 37 (1935) 313-314

(H M B)

A Urinary Antiseptic A new urinary antiseptic "picochrome" was found to act equally well in acid and alkaline urines and that it destroyed coliform bacilli as well as cocci It is potent in high dilutions and is tolerated orally, intravenously or locally The only drawbacks are diarrhoea occasionally, and red discoloration of the urine The drug is a derivative of orthocresyl, and contains a new radical called diaminiopicoline—A RAVICH *Med Record*, 142 (April 3 1935) 343, through *Brit Med J*, 3893 (1935), 326C

(W H H)

Vincent's Angina—Preliminary Evaluation of a Solution of Cerous-ceric Chromate in the Treatment of, and Other Oral Diseases Cerous ceric chromate (I) seems to offer a powerful oxidizing agent to the dental profession for the treatment of Vincent's infection It does not have a persistent stain, is not disagreeable in taste and has no odor It is prepared by combining at high temperature ceric oxide and chromic acid The resulting mixture is apparently equal percentages of ceric and cerous chromates It has been found particularly efficient in combating chronic and acute forms of Vincent's infection especially in the fusiform stage Two cases, 1 acute and 1 chronic of 4 year's duration are reported The disadvantages of the oxidizing agents hydrogen peroxide, perborates, potassium permanganate, mercury salts and chromic acid are discussed—D C LYONS and O T COFFELT *Dental Digest* 41 (1935), 201, through *Squirrb Abstr Bull*, 8 (1935), A-1018

Vinethin—New Hypnotic Vinethin is characterized by its production of quiet sleep and freedom from production of undesirable side actions—E W DORFFEL *Deut Med Wochenschr*, 61 (1935), 955-957

(H R)

Vitamins A and D and Camphor Oil—Use of, in the Treatment of Burns Local application of 7% camphor oil combined with vitamin A and D given by mouth cause quick disappearance of toxic symptoms produced by burns—CARLOS O FRANZETTI *Semana med (Buenos Aires)*, 42 II (1935), 998

(A E M)

NEW REMEDIES

SYNTHETICS

Apothyrin Dragees (Dr Wander G m b H, Vienna) contain 0.05 Gm diiodothyrosin per tablet in packages of 30 dragees—*Pharm Post*, 68 (1935) 388

(H M B)

Azochloramid (Wallace and Tiernan Products, Belleville, N J) is N,N'-dichloroazodicarbonamidine and an effective stable chlorine germicide for therapeutic use and is recommended for dressing packing or irrigating infected wounds and cavities—*Drug and Cosmetic Ind*, 37 (1935), 127

(H M B)

Dibroluur (Soc Chem Ind Katwijk, Netherlands) is bromodiethylacetylurea in 0.5-Gm tablets—*Drug and Cosmetic Ind*, 37 (1935), 127

(H M B)

Isopur Tablets (F J Kwizda, Korneuburg) are marketed in packages of 10 tablets of 0.15 Gm dioxanthraquinone—*Pharm Post*, 68 (1935), 388

(H M B)

Natriphene (Natriphene Co, Detroit) is a white crystalline powder, sodium 2 hydroxydi phenyl with a phenol coefficient of 17 $\frac{1}{5}$ as toxic as phenol, soluble in water, alcohol and acetone and is used as a disinfectant, antiseptic, fungicide and deodorant—*Drug and Cosmetic Ind*, 37 (1935), 127

(H M B)

Neonal Sodium (Abbott Laboratories) is the sodium salt of butyl ethyl barbituric acid, and is claimed to be about three times as active as barbital—*Drug and Cosmetic Ind*, 37 (1935), 263

(H M B)

Phenyl Aspirodine (W Martindale, London) is acetyl iodosalol and is recommended for use as an intestinal and urinary antiseptic—*Drug and Cosmetic Ind*, 37 (1935), 263

(H M B)

Rosidol (Leopold Laseyron, Paris) is 2,6 dimethyl octen(2)ol (8) — *Riechstoff-Ind Kosmetik*, 10 (1935), 160 (H M B)

SPECIALTIES

A M O Antiseptic Solution (Boots Pure Drug Co, Nottingham) is a solution containing amy 1-m cresol for a mouthwash dental antiseptic or gargle — *Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Abszessin (Rego A G, Schwanden) are tablets containing 0.1 Gm morphine (1 Gm opium or 0.5 Gm of extract) with rice starch and cocoa powder — *Pharm Monatsh*, 16 (1935), 135 (H M B)

Adol Potion (Adol Laboratory, Lyon) contains ammonium bromide 5 Gm, pyramidon 3 Gm, caffeine citrate 0.15 Gm, ammonium iodide 0.5 Gm, sparteine sulphate 0.1 Gm, extract of valerian 0.8 Gm, excipient to form a liqueur 20 Gm. One to 5 dessertspoonfuls are taken per day to combat pain — *Bull Ch Synd Pharm Seine* (July 1935), through *J pharm Belg*, 17 (1935), 710 (S W G)

Ambinon (Organon, Ltd Netherlands) is a purified extract of the anterior lobe of the pituitary body of which it contains the active constituents. The thyrotrope hormone of the anterior lobe of the pituitary body stimulates the activity of the thyroid gland which is coupled with an increase in elementary changes and with the iodine content of the blood. For standardization of the guinea pig unit, half of the daily dose which if injected intraperitoneally in young guinea pigs (150–200 Gm) reaches or exceeds a fixed epithelial development of the thyroid gland is selected. This unit is about equal to the Junkmann and Schoeler unit, although the latter is somewhat less sharply defined. Each ampul of Ambinon contains 25 guinea-pig units of thyrotrope hormone. The gonadotrope hormone of the anterior lobe of the pituitary body possesses a strongly stimulating action on the ovary. It promotes ripening of the follicles and the development of the corpus luteum. Recent research seems to show that the ripening of the follicles is caused by two components of the gonadotrope hormone, both of which are present in Ambinon. Each ampul of Ambinon contains 5 rat units of gonadotrope hormone. Still another important property of the gonadotrope hormone is that it increases the action of the gonadotrope hormone of the urine of pregnant women (pregnyl). In order to facilitate the simultaneous administration of ambion and pregnyl, the ambion ampuls are packed with an equal number of pregnyl ampuls. The latter is in powdered form which is put into solution for use, since the solution is unstable and has poor keeping qualities. Among other things Ambinon is employed in habitual abortion, infantile and primary amenorrhoea, in insufficient development of the testes and in disturbances of the thyroid function or of metabolism. In general, one is directed to inject one ampul every day or every other day, usually not combined with pregnyl — *Pharm Weekblad*, 72 (1935), 1040 (E H W)

Amos Throat Water (Dr O Seiderer, Germania Apothecary, Dresden) is a solution of aluminum chloride with the addition of perhydrol used in throat inflammations, gripes, etc — *Pharm Monatshefte*, 16 (1935), 135 (H M B)

Antagosin (Behringwerke, I G Farbenindustrie A G, Leverhusen a Rh) is a lactic acid bacterial preparation for local inflammatory treatment due to developed bacterial infection. The preparation contains antagonistic acting lactic acid bacteria which due to its biological activity hinders the growth of pathogenic bacteria. The preparation is simultaneously used for disinfection and astringency, but rinsing must be unconditionally avoided to prevent any antagonistic action. The preparation is marketed in sealed dark bottles which are shaken before use and stored in a cool place — *Pharm Zentrall*, 76 (1935) 536 (E V S)

Antetestin (Gedeon Richter, London) is a combination of gonadotropic hormone and testicular extract sold as tablets or ampuls with a dose of 1–2 tablets 3 times a day or 1 intramuscular injection — *Drug and Cosmetic Ind*, 37 (1935), 263 (H M B)

Anthesin (Sandoz Chemical Works), the N diethyl leucinol ester of *p* aminobenzoic acid, is a local anesthetic and is used for infiltration anesthesia and spinal anesthesia in conjunction with adrenalin solution — *Drug and Cosmetic Ind*, 37 (1935), 263 (H M B)

Anthrex Suppositories (Sagitta Works G m b H, Munich) against gout, rheumatism, and arthritis, contain Investin (a molecular combination of diethylbarbituric acid, amidophenazon, phenacetin and caffeine citrate) and phenylquinolincarbonic acid — *Pharm Monatshefte*, 16 (1935), 135 (H M B)

Argyrophedrine (Aron Suresnes) contains ephedrine hydrochloride 0.3 Gm, Argryol Barnes of 0.3 Gm, physiologic serum 30 cc. It is used as a nasal spray or in the form of drops—*Bull Ch Synd Pharm Seine* (May 1935), through *J pharm Belg*, 17 (1935) 572 (S W G)

Arthrorheumin (Kaiserdaim Apothecary, Charlottenburg) occurs in ampuls with the following composition: Formic acid 0.001 Gm, silicic acid anhydride 0.0001 Gm, phosphorous 0.0000166 Gm, arsenic 0.0000166 Gm, strychnine 0.0000125 Gm, water q s to 1 Gm and is used for gout, chronic muscular rheumatism, lumbago, etc.—*Pharm Monatsh*, 16 (1935), 135

(H M B)

Azoule Calcium L-B (Allen and Hanburys, London) is a solution of calcium lactobionate for the parental administration of calcium in tetany, etc.—*Drug and Cosmetic Ind*, 37 (1935), 127

(H M B)

Binæmon (Organon Ltd) consists of liver powder and powdered hog stomach. It is a preparation containing anti-anemic factors of liver and hog stomach. The intrinsic factor of Castle as well as the extrinsic factor shown by recent researches that the mucous membrane of the stomach should be combined with liver, are present in this preparation. The patient can take Binæmon at meal time. Ten-15 grams are sufficient in most cases to regenerate the blood. Clinical research must still show the value of this preparation in convalescence. It has already been shown that patients who have returned to a normal blood count with liver injections, have with this preparation retained the erythrocyte count and patients seriously ill have had an increase in red blood corpuscles—*Pharm Weekblad*, 72 (1935) 1041

(E H W)

Borhamyl (H. Martinet Paris) consists of salicylic acid 0.1 Gm, boric acid 5 Gm, concentrated distillate of *Hamamelis virg* 50 Gm, distillate of plantain 50 Gm, distillate of melilot 50 Gm, distilled water enough to make 250 Gm. The solution is isotonic with the tears and may be used as an eyewash—*Bull Ch Synd Pharm Seine* (May 1935) through *J pharm Belg*, 17 (1935), 572

(S W G)

Calbrolact (Chris Zimmermann and Co, London) is a combination of calcium bromide (33%) and calcium lactate (66%) with a dose of 2-6 tablets daily—*Drug and Cosmetic Ind*, 37 (1935), 263

(H M B)

Camphochin (Karl May Besch Pharmaceutica G m b H, Berlin Wilmersdorf) is a sterile ethereal oil solution containing 3% of basic quinine and 2.5% of camphor. It is used as a painless intramuscular or intragluteal injection in bronchopneumonia, bronchiectasis, etc.—*Pharm Zentralh*, 76 (1935), 553

(E V S)

Canfidrol Ampuls (Laboratory Farmacol Reggiano, Corregio Italy) contain calcium camphosulphonate and ephedrine hydrochloride in packages of 6 × 1 cc and 3 × 5 cc ampuls and as packages of 15 cc of solution—*Pharm Post*, 68 (1935) 327

(H M B)

Certosed (Sagitta-Werk G m b H, München) is prepared from the extracts of valerian, viscum and opium, tincture of strophanthus and chloral hydrate. It is used as a sedative and hypnotic for nervous disorders and worries, especially for heart neurotics—*Pharm Zentralh*, 76 (1935), 460

(E V S)

Cholotonon (Chem Fabrik Promonta G m b H, Hamburg 26) is prepared from an extract of the liver and gall bladder systems. It is marketed only in ampuls and used in disorders of the liver and in the gall bladder ducts—*Pharm Zentralh*, 76 (1935), 430

(E V S)

Clabin (Sagitta-Werk G m b H München), a corn and callous remedy is a combination of salicylic collodion, resorcinol collodion and salicylic acid—*Pharm Zentralh*, 76 (1935), 536

(E V S)

Codalgin (S. Ballin, Frankfurt a M) tablets contain in each codeine phosphate (0.01 Gm) caffeine (0.05 Gm), phenacetin (0.25 Gm) and phenyldimethylpyrazolone (0.25 Gm). It is used for gripe, migraine, head and toothaches, and rheumatism—*Pharm Zentralh*, 76 (1935) 460

(E V S)

Corron Tablets (Abbott Laboratories) are a convenient source of iron and copper and are recommended for preventing nutritional and secondary anemias—*Drug and Cosmetic Ind*, 37 (1935), 263

(H M B)

Cortical Fluid (Fa Istituto Opoterapico Pisa) is the aqueous extract of fresh suprarenal cortical substance in packages of 40 cc and ampuls in packages of 6 × 2 cc—*Pharm Post*, 68 (1935), 327

(H M B)

Cortidyn (Chem Fabrik Promonta G m b H Hamburg) is a standardized kidney extract

prepared by a special process from the suprarenal cortex of freshly killed animals. One cc of the extract contains 5 corticodynamic mouse units. A mouse unit dose of the extract will cause an increase in weight of a young desuprarenalized mouse from 9 to 11 Gm in seven days and the animals should be alive in 80% of the test cases eight days after the operation. It is used intramuscularly or subcutaneously in Addison's disease, Basedow's disease, infectious diseases and psoriasis.—*Pharm Zentralh*, 76 (1935), 554 (E V S)

Cumasina Preparations (Angelini Werke G m b H, Leipzig), based on the system of silver antiseptics and chlorine disinfection of Kruse Fischer, contain oligodynamic bactericides due to the finely distributed and effectively activated non poisonous Cumasina silver obtained by an electric current. *Cumasina liquid* is used for instillations, spraying, inhalations, gargling, wounds or ulcers, abscesses, mucous membranes, etc., *Cumasina liquid forte* for gonorrhea, *Cumasina liquid angina* for the treatment of angina, *Cumasina powdered I* for dishydrosis and hyperhydrosis, *II* for *pruritis senilis*, *III* for eczema and burns, *IV* for ulcers and abscesses of various types or stomatitis, *Cumasina ointment* for frost-bite and burns of all forms, *Strong Cumasina ointment* for the treatment of *ulcus cruris*, *Cumangin troches* for angina and inflammable conditions of the mouth and throat, *Cumadiph tablets* for diphtheria, *Cumacargo tablets* for intestinal infections, enteritis typhus and dysentery, and *Cumanellen* as a prophylactic for mouth, throat and larynx disinfection.—*Pharm Zentralh*, 76 (1935), 554 (E V S)

Curacine Tin Compound Tablets (Cooper Laboratory, Watford, Herts) consists of tin oxide and metallic tin in a suitable base for the treatment of staphylococcal diseases.—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Darmo-Stop Tablets (Lab Farmacol Reggiano, Corregio, Italy) in packages of two tablets contain 0.50 Gm basic calcium aluminum tannate in chocolate.—*Pharm Post*, 68 (1935) 327 (H M B)

Davitamon A-D (Organon Ltd) is now obtainable in vials (dragees) each vial containing 1500 International Vitamin A units and 1000 International Vitamin D units. The oily solution contains 5000 International Vitamin D units and 6000 International Vitamin A units per cc and corresponds to about 5 dragees in Vitamin D content. The new form should be attractive for children's use and has the advantage of eliminating the loss incurred by dropping from the bottle. It is found on the market in boxes of 24 and flasks of 100.—*Pharm Weekblad*, 72 (1935), 1041 (E H W)

Dermichthol (Ichthyol Company) contains *Leukichthol* with phenol, salicylic acid, terpenes and *Unguentum Basilicum*. It is used in pyodermitis, abscesses of the sweat glands, phlegmones etc.—*Pharm Weekblad*, 72 (1935), 1041 (E H W)

Digitalid (Sandoz, Basel) contains the active crystalline constituents from *Digitalis lanata* recently described by Stoll and Kreis. It contains three glucosides from this digitalis species. According to Rothlin it may be considered as a crystalline infusion of digitalis in which the active constituents appear in unaltered form. It is found upon the market in 0.5% solution, in tablets containing 0.25 mg of glucosides and in suppositories with 0.5 mg. According to experiences at the University clinic at Leipzig, it gives satisfactory results in cases for which in the past a combination of strophanthin and salyrgan had been used.—*Pharm Weekblad*, 72 (1935), 1041 (E H W)

Duroxyl Tablets (Kronik and Edels, Vienna) in packages of 10 tablets to 1 Gm consists of hydrogen peroxide in solid form (carbamide + 30% H₂O₂).—*Pharm Post*, 68 (1935), 387 (H M B)

Dysmenural is a combination of Uzara and phenyldimethylpyrazolon. It is found on the market in tubes of 10 tablets each weighing 0.7 Gm. It is used to diminish labor pain, and in spastic dysmenorrhoea. The dose is 1 tablet three times a day.—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Eciphun is the name given by Nourypharma Ltd (Deventer) to ephedrine hydrochloride. It is placed on the market by this firm in tablets containing 0.05 Gm of the alkaloid and in ampuls containing 1 cc of a 5% solution.—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Eciphun-Hæststroop (Nourypharma Ltd) is a thyme syrup containing 2.5 mg of Eciphun (ephedrine hydrochloride) per cc. The syrup is given in by teaspoon and is used in whooping-cough, and to reduce the cough stimulus in coughs due to colds.—*Pharm Weekblad*, 72 (1935) 1042 (E H W)

Eciphin-Neusglei (Nourypharm Ltd) is a nasal ointment (jelly) which contains ephedrine menthol and eucalyptol. It is put up in tin tubes having a nozzle to facilitate the application of the jelly in the nasal cavity. It is used for head colds—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Emenagon (Chem pharm Fabrik Progrede G m b H Köln) contains the extracts of *Pareira brava*, petroselinum and cascara, *Crocus elect*, senna leaves, myrrh and iron lactate. It is indicated in amenorrhoea, dysmenorrhoea, and menstrual and climacteric complaints—*Pharm Zentralh*, 76 (1935), 460 (E V S)

Epokan Merck contains in each tablet or ampul 0.03 Gm of pyrazine carbonylhydrazide, 0.03 Gm of ephedrine cumarin carbonate, and 0.0002 Gm of pseudotropine benzoic hydrochloride. It is indicated for use in asthma and other asthmatic conditions. The dose is 2-3 tablets or 1-2 ampuls subcutaneously or intravenously depending upon the severity of the case—*Pharm Zentralh*, 76 (1935), 554 (E V S)

Eroxan-Noury (Nourypharm, Ltd) is a 25% magnesium peroxide identical with similar products found on the market. It is prescribed in 1-2 teaspoonful doses for stomach disturbances—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Eurysin (Hamburger Serumwerk G m b H, Hamburg 39), a preparation useful in non specific immunity therapy contains the albuminoid and lipid substances of apathogenic bacteria made soluble by a special ferment. The preparation is intramuscularly or suitably intragluteally injected for grippe, pneumonia, sepsis, erysipelas or furunculosis—*Pharm Zentralh*, 76 (1935), 536 (E V S)

Ferfersan (Dr Oelrich & Co, Chem pharm Laboratorium, Berlin) is an iron and calcium combination with a fish liver extract which has been specially prepared from the blubber free portion of the fish liver. It is used in cases of anemias, chlorosis, scrofulosis, rickets, etc—*Pharm Zentralh*, 76 (1935), 554 (E V S)

Folinerin (Schering Kahlbaum) is a glucoside obtained from the leaves of *Nerium Oleandri*. This glucoside crystallizes from dilute alcoholic solution in prisms. It rotates the plane of polarized light to the left, has a molecular weight of 522 and a possible formula $C_{39}H_{46}O_8$. It acts in the same way as digitoxin, although the action is of longer duration and it does not possess the cumulative action of digitalis. The cat unit according to Hatcher-Magnus is 0.24 mg per Kg and by intravenous injection 0.12 mg. One mg corresponds to about 1200 frog units—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Gonacrine Ampuls (Dr Fritz Zuckerhendl Vienna) is marketed in packages of 3 ampuls of 5 cc of 2% aqueous solution of 3,6 diamino 10 methylacridin hydrochloride or 6 ampuls of 5 cc of 0.50% solution—*Pharm Post*, 68 (1935), 387 (H M B)

Grumonal (Sagitta Werk G m b H, München) is a specially prepared tasteless and odorless castor oil—*Pharm Zentralh*, 76 (1935), 460 (E V S)

Gynichtol (Ichthyolgesellschaft, Cordes Hermann & Co Hamburg) is a tampon solution containing antipyrine, potassium iodide, glycerin and Leukichtol—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Hédéryl (Lettry Laboratories Paris) consists of fluid extract of ivy 10 Gm, essence of origanum 20 drops in 100 Gm. It is applied with friction against cellulitis—*Bull Ch Synd Pharm Seine* (July 1935), through *J pharm Belg*, 17 (1935), 710 (S W G)

Hepastab (Boots Pure Drug Co, Nottingham) is a concentrated sterile solution of the anti-anemic factor of mammalian liver used for pernicious anemia—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Hepatopson forte (Chem Fabrik Promonta G m b H, Hamburg) is a highly concentrated liver extract suitable for intramuscular injection. Two cc of the preparation has the equivalent effect as 5 Kg of fresh liver taken orally. It is used in severe cases of Biermer's anemia—*Pharm Zentralh*, 76 (1935), 554 (E V S)

Hepatose (Chemische Werke, Pirmasens) contains the active principles of the liver and gastric tract. It is indicated for use in anemias and disorders of the stomach, liver and gall bladder—*Pharm Zentralh*, 76 (1935), 430 (E V S)

Hormotone (G W Carrick Co) is a combination of the tonic hormones of thyroid, pituitary, suprarenal and gonads and is used for neurasthenia, etc—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Hypotan (Anglo French Drug Co, London) contains the bromide salts of synthetic choline derivatives with chloral and is used as a vasodilator for the relief of arterial spasms—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Incretone (G W Carrich Co) is a bitter tonic—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Iod-Turipol (Drs R and O Weil, Frankfurt) is composed of Turipol (terpene and pinene containing paraffin oil) and 0% iodine in organic combination is used in the nose by means of a special dropping pipette for chronic atrophic catarrh of the nose and throat—*Pharm Monatshefte*, 16 (1935), 136 (H M B)

Kitano (Kitano Co, London) consists of ammonium sulphocithiolyate 2 parts, zinc hydroxycarbonate 6, adeps lanae 6, flores zinci 24, liniment calcis 66 and is used for the treatment of skin disorders—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Kurabo (Eupharma, Passau) is an analgesic and antipyretic in the form of tablets which contain acetanilid 0.10 Gm, dimethylamidoantipyrin 0.10 Gm, caffeine 0.05 Gm, phenacetin 0.25 Gm per tablet—*Pharm Monatshefte*, 16 (1935), 137 (H M B)

Kynerval (Kyffhäuser Laboratorium Bad Frankenhausen), a nerve sedative, contains calcium bromate, extract of valerian, humulus, frangula, peppermint, iron citrate and carrot—*Pharm Zentralh*, 76 (1935), 460 (E V S)

L P C Proderma Soap (Deutsche Lupocid Gesellschaft Meunzer and Peter Karlsruhe (Baden)), for eczema, contains as active ingredients lecithin and chlorocavacrol—*Pharm Zentralh*, 76 (1935), 536 (E V S)

Laccodermes (Lab Brisson) is a water soluble "semi fatty" varnish of which the excipient is an ointment of casein. It forms a supple, elastic and resistant coating on the epidermis, and may be used with dermatologic preparations—*Bull Ch Synd Pharm Seine* (May 1935), through *J pharm Belg*, 17 (1935), 572 (S W G)

Lebergranulat (Merck, Darmstadt), for diet therapy, contains the active principles of liver prepared and concentrated by a special fermentative process so that a small dose would have the same effect as the use of a large quantity of fresh liver or dried liver preparations. The small dose of the preparation is easily taken so that continual administration does not overtax the patient. It is used for Bremer's anemia and for pernicious anemias—*Pharm Zentralh*, 76 (1935), 554 (E V S)

Lecitrapp (Dr Schmidtsche Apotheke, Inhaber Otto Trapp, Tübingen) contains the purest colloidal egg lecithin sodium biphosphate, organic iron with copper as a catalyst, dextrose and plant extracts. It is marketed in liquid form, or in tablets with the addition of cola. It is used as a nerve tonic, for anemias, and as a regenerative especially for the heart, nerves, exhaustion and anemia—*Pharm Zentralh*, 76 (1935), 430 (E V S)

Leukachthol (Ichthyol Gesellschaft, Cordes Hermann & Co, Hamburg) is a new, almost colorless Ichthyol. It is almost odorless, dark in substance but light in thickness. Differences in therapeutic value are not given—*Pharm Weekblad*, 72 (1935), 1042 (E H W)

Limentum Rubbeck (United Laboratories Ludovica, Ludwig Sell, Munich) for acute and chronic articular rheumatism, neuralgia, etc., is a liniment of salicylic acid, methyl salicylate, capsin and oils of eucalyptus, salvia, mace, rosemary, juniper and camphor in solution—*Pharm Monatsh*, 16 (1935), 121 (H M B)

Lutin-salve (Togal Works of Gerhard F Schmidt, Munich), useful against acute and chronic articular and muscular rheumatism, gout, neuralgia, etc., contains oil turpentine, solution of amyl salicylate, acid salicylic, camphor, menthol and adeps lanae—*Pharm Monatsh*, 16 (1935), 121 (H M B)

Lorisan (Chem-Pharm Laboratories of Eduard Lyse, Dresden) is sold as Lorisan I (mild) and Lorisan II (strong). (I) consists of anhydrous lanolin, zinc oxide, liquid petrolatum, rosemary oil, formic acid, gallic acid, arnicin, matico oil, judlandin, oil of chamomile, volatile oils and various glucosides and is used for inflammations of the skin, furunculosis or carbuncles, muscles, tendons, wounds, etc.—*Pharm Monatsh*, 16 (1935), 121 (H M B)

Luteal Ampuls (Fa Istituto Opoterapico Pisa) is the aqueous extract of corpus luteum and is sold in packages of 6 ampuls of 1 cc—*Pharm Post*, 68 (1935), 327 (H M B)

Luteolpex (Sanabo Chinoi, Fabrik chem-pharm Präparate G m b H Wien XII) is a corpus luteum hormone in oil solution standardized according to the method of Corner. Each 1-cc

ampul contains ten clinical units. It is used as a preventative in habitual abortion and to control the bleeding of pregnancy.—*Pharm Zentrallh*, 76 (1935), 460 (E V S)

Magsalyl (A Roux, Ivry sur Seine) is a physiologic solution of sodium salicylate in biologic equilibrium with the sodium calcium, potassium and magnesium ions of the blood serum. It contains sodium salicylate 0.5 Gm, magnesium chloride 0.05 Gm, magnesium hyposulphite 0.075 Gm, excipient enough to make 5 cc.—*Bull Ch Synd Pharm Seine* (June 1935), through *J pharm Belg*, 17 (1935), 672 (S W G)

Map (Dr George Henning, Berlin Tempelhof) is crystallized inyo adenosine phosphoric acid and is said to be useful in overcoming ischemia and anoxemia of the heart muscle, relieves spasms of the peripheral vessels and is suggested for angina pectoris and gangrene, 1-3 cc may be given by intramuscular injection daily.—*Drug and Cosmetic Ind*, 37 (1935), 263 (H M B)

Mastal-liquid (Istituto Opoterapico Pisa) is the aqueous extract of fresh mammary glands in packages of 60 cc and also sold in packages of 12 ampuls holding 2 cc.—*Pharm Post* 68 (1935), 327 (H M B)

Medulka Frostbite Ointment (Dr W Dermbach, Apotheker, Bad Salzschlief) is a mixture containing eucalypt, larch terpeatine ethyl p aminobenzoate, ointment of alther and boae marrow.—*Pharm Zentrallh*, 76 (1935), 353 (E V S)

Menotheosan Dragees (Dr Wander G m b H Vienna) consist of 0.10 Gm bromine calcium theosan, 0.02 Gm sodium nitrite phenylethylbarbituric acid, papaverine dioxanthraquinone and ovarium in packages of 60 dragees.—*Pharm Post* 68 (1935), 387 (H M B)

Mercollod Ampuls (Biochemischen Laboratorien A G, Locarno) contains 0.01 Gm colloid mercury sulphide and is given for luetic and paralytic disorders especially those resistant to arsenic and bismuth and also for psoriasis.—*Pharm Monatsh*, 16 (1935), 121 (H M B)

Mugantheme (Chint Nef u Cie Genf) is a maybell perfume used for cologne waters skin creams and powders.—*Riechstoff Ind Kosmetik*, 10 (1935), 160 (H M B)

Myrtazeenol Reinecke (Fabrik fur pharm Spezialitäten, Homöopathische und Biochemie G A Reinecke, Hannover), a preparation containing 80-85% of oil of eucalyptus, is used either internally or externally for rheumatism, gout ischias, asthma headache or coughs.—*Pharm Zentrallh*, 76 (1935), 536 (E V S)

Nembotal (Abbott Laboratories) a sedative, hypnotic and antispasmodic is offered as an elixir in 4 oz and 1-pint bottles and in suppositories containing 2 grs.—*Drug and Cosmetic Ind*, 37 (1935), 263 (H M B)

Nerosol C (L Givaudan u Cie Genf) is a new elixir form of nerol especially good as a perfume for cologne waters.—*Riechstoff Ind Kosmetik* 10 (1935), 160 (H M B)

Nervanon (Fabrik pharm Präparate A Zwintseher, Heidelberg) contains valerian, hops, *Viscum album*, and a dilution of strophanthus (D 3). It is used for nervous disturbances of various types, and for climacteric conditions such as the pains during menstruation.—*Pharm Zentrallh*, 76 (1935), 537 (E V S)

Nouricalpæder (Nourypharma Ltd, Deventer) is a mixture containing 25% calcium gluconate, 25% dry extract of malt and 50% sugar. It is a dietetic preparation which is principally used in children's porridge to promote calcium assimilation. This is brought about especially by the addition of the extract of malt. A teaspoonful is used to a dish of porridge. For the regular administration of calcium *Nourical chocoladchagelslag* and *Nourical muisjes* (both confections) are found on the market, and serve as pleasant vehicles for children.—*Pharm Weekblad*, 72 (1935), 1043 (E H W)

Nouricaltabletten (Nourypharma Ltd, Deventer) are tablets containing 1.5 Gm of calcium gluconate. They are flavored with oil of peppermint which makes the administration of the calcium preparation more pleasant.—*Pharm Weekblad*, 72 (1935), 1043 (E H W)

Novalgin-Quinine (Bayer, I G Farbenindustrie Aktiengesellschaft, Leverkusen), sold as tubes of 10 dragees and containers of 100 dragees, contains 0.15 Gm of sodium phenyl dimethyl pyrazolone methyl ammonomethane sulphoate and 0.1 Gm of the quinine salt of the same acid (= 0.05 Gm quinine) in each dragee. It is given by mouth 1-2 dragees 1-3 times a day for grippes pains of all kinds joint and muscular rheumatism and neuralgias.—*Apoll Ztg* 50 (1935), 406 (H M B)

Nymphosan-Peru-Gummibonbons (Nymphosan A G, Munich) contain balsam peru 1.6%, anesthesin 0.8% and sugar, and is used for colds and disorders of the air passages — *Pharm Monatsh*, 16 (1935), 121 (H M B)

Oxyascarin Tablets (Brandt and Co, Halle) is marketed in packages of 10 tablets containing 0.0075 Gm aluminum subsulfate, triethyl diphenol ester and aluminum subacetate — *Pharm Post*, 68 (1935), 387 (H M B)

Oxykin Cream A formula is cited for a contraceptive cream recommended by Dr J H Leunbach. This is composed of oxyquinoline sulphate, 1 Gm and *Cremor ad explorationem*, 99 Gm — *ANON Arch Pharm og Chemi*, 12 (1935), 151 (C S I)

Pallida Antigen (Sächsischen Serum Works A G, Dresden) is a Pallida pure culture extract serving for the serological detection of lues — *Pharm Monatsh*, 16 (1935), 122 (H M B)

Pantigal Plugs (F. Beiersdorf and Co, Vienna) are sold in packages of 3, 6, 12 pieces, each containing 0.30 mg linadigin glucoside from digitalis lanata — *Pharm Post*, 68 (1935), 388 (H M B)

Paralact Tablets (Cooper Laboratory) consist of parathyroid and calcium lactate to be used in cases of defective calcium metabolism — *Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Paspas (Ludpoldwerk, Munich) is a mixture of polyvalent antigen with powdered posterior lobe of pituitary body. It is used as a vaccine in the treatment of bronchial asthma. Each ampul contains 0.2 cc Paspas, the unit for one treatment. With children the quantity is cut in half. Six skin scratches are made on the upper arm with a lancet. These should be 1/2 to 3/4 cm long and about 1/2 mm deep. Some blood may appear. Two-3 drops of the Paspas is then well rubbed into the area with a glass rod and the remainder slowly added from a syringe. After drying, a bandage is applied. Ten treatments covering 12-14 days are usually used — *Pharm Weekblad*, 72 (1935), 1043 (E H W)

Pelargon (Deutsche A G für Nestle Erzeugnisse, Berlin Tempelhof) is a powdered lactic acid whole milk without the addition of carbohydrate. It is prepared from first class fresh milk obtained from cows in the Swiss Alps with the addition of 0.5% of a pure lactic acid. It is used to prepare milk for infants and children as the normal nutrient or to supplement the mother's milk, and as a dietetic food for various convalescences, eczema and vomiting — *Pharm Zentrall*, 76 (1935), 461 (E V S)

Pep-Acid-tabletten (Nourypharma, Ltd, Deventer) contain 0.4 Gm betaine hydrochloride and 0.1 Gm pepsin. They are used after meals in indigestion — *Pharm Weekblad*, 72 (1935), 1043 (E H W)

Perboraat Noury (Nourypharma, Ltd, Deventer) is sodium perborate flavored with peppermint oil. It is packed in square bottles and is used in place of tooth powder, tooth paste and mouth washes. A small quantity of the preparation may be placed on the tooth brush, or may be dissolved in water — *Pharm Weekblad*, 72 (1935), 1043 (E H W)

Peremesin (von Heyden Chemical Co) is a colloidal cerium ovalate preparation used to prevent vomiting. It is used as a preventative for sea sickness and to correct the tendency toward vomiting in pregnancy. One-2 tablets — *Pharm Weekblad*, 72 (1935), 1043 (E H W)

Perinkret (Chem Fabrik Dr George Henning Berlin Tempelhof) is a peristaltic hormone which is obtained as the neohormonal from the spleen. It is a much concentrated preparation representing in 2 cc the therapeutic action of about 20-30 cc neohormonal and is used against chronic constipation and intestinal paralysis — *Pharm Monatsh*, 16 (1935), 122 (H M B)

Pertugen Ointment (Anhaltisches Serum-Institut G m b H, Berlin-Dessau) is an aluminum chloride in a specially prepared ointment base having a high water absorbing power. The action of the preparation depends upon the liberation of nascent chlorine and oxygen, whereas the aluminum salt exerts its anti-inflammatory and antiseptic action. It is used for skin burn, frostbite, leg ulcers, hemorrhoids, etc — *Pharm Zentrall*, 76 (1935), 461 (E V S)

Pertussin Troches (E. Taeschner, chem-pharm Fabrik, Potsdam) contain as active ingredients Pertussin balsam, Extract Thyme Taeschner, ephedrine hydrochloride and extract lobelia. The troches for children contain Pertussin balsam, quinine dihydrochloride, carbamide, phenylethylbarbituric acid and a small amount of powdered extract of belladonna. They are used for pertussis, bronchitis, bronchial asthma, etc — *Pharm Zentrall*, 76 (1935), 554 (E V S)

Perviseal (C Sorger, Apotheker, Wolmirstedt, Bez Magdeburg) is prepared from fresh plants of *Vascum album*, drug extracts of celery seed, *Auriculus muris*, adonis and homeopathic doses of vanadium chloride and cerium oxalate. It is indicated for use in arteriosclerosis and similar conditions — *Pharm Zentralh*, 76 (1935), 554 (E V S)

Pharyngil (Sachsischen Serum Works A G, Dresden) contains neo pyocyanase 15%, water free glycerin 80% and different anesthetics 5% and is used for the quick removal of irritations and inflammations of the throat and the upper air passages by spraying — *Pharm Monatshefte*, 16 (1935), 122 (H M B)

Phosoforme Drops (Drouet et Plet, Paris) contain o phosphoric acid and 30% ethyl ester of phosphoric acid. An ethoxy determination shows that the ester consists of 19.34% monoethyl derivative and 11.82% of the diethyl derivative — *Pharm Monatshefte*, 16 (1935), 138 (H M B)

Physormon-Schnupf Powder (Chem fabrik Promonta G m b H, Hamburg) is a powder containing in 1 Gm 100 Voegtlin units of posterior pituitary substance for the rapid use in diabetes insipidus — *Pharm Monatshefte*, 16 (1935), 122 (H M B)

Pigofusin (Pharin Industrie Gesellschaft, Offenbach) is an isotonic sterile convenient liquid for infusions and injections and has a salt content similar to that of sea water — *Pharm Monatshefte*, 16 (1935), 122 (H M B)

Polymalan (Dr Sidler and Co G m b H, Freiburg) is an alcoholic ether boroglycerin salicylic acid ester solution with compound tincture of capsicum and balsam peru used for rheumatism and gout. For internal use it is sold as capsules — *Pharm Monatshefte*, 16 (1935), 122 (H M B)

Prophylactic Kit. A venereal prophylactic kit designed by the Danish Apothecaries Society is described. Three grams of *Sol Argenti Nitrat*is prophylact and a 10 Gm tube of *Unguentum Calomelanos prophylacticum* are provided together with means of application — *Anon Arch Pharm og Chem*, 42 (1935), 451 (C S L)

Provelnase Midy (Midy Works Vienna) is a tonic for the venous walls, and is used in the form of tablets in phlebitis, œdemas hemorrhoids, circulatory disturbances. For acute cases doses of 3-6 tablets are given daily, for chronic cases 2-4 tablets daily — *Pharm Monatshefte*, 16 (1935), 123 (H M B)

Prusenilla Powder (Hoffman and Kohler Altona) to combat *pruritis senilis* and dyshidrose consists of salicylic terpene esters finely divided into an antiseptic powdered substance — *Pharm Monatshefte*, 16 (1935), 123 (H M B)

Pudan Head and Foot Powder (Scott & Bowne G m b H Kosmetische Abteilung, Frankfurt a M) is a specially prepared spongy tale, the small particles of which are coated with a skin related fat which is easily reabsorbed from the skin. The powder also contains salicylic acid — *Pharm Zentralh*, 76 (1935), 461 (E V S)

Puerperalfieber-serum (Concentrated Streptococcus Serum) (Behringwerke " I G Farbenindustrie, Aktiengesellschaft Leverkusen) in ampuls of 25 cc, is administered intramuscularly in 50 cc doses for severe cases of puerperal sepsis — *Apoth Ztg*, 50 (1935), 365 (H M B)

Purosan (Purosan Nährmittel G m b H Leipzig C 1) is a dried beer yeast for the prevention and treatment of diseases. It is rich in vitamin D due to intensive ultraviolet irradiations. The preparation is taken internally for skin diseases, diabetes scrofula tuberculosis, anemia, rickets and chronic women's diseases and externally where fluorine is in use — *Pharm Zentralh*, 76 (1935), 461 (E V S)

Pyrestasin (Synochem Präparate Gesel, b H Berlin) is an analgesic in rheumatism and neuralgias and consists of a combination of molecular quantities of ethyl ester of aminobenzoic acid and dimethylaminophenyldimethylpyrazolon (about 2.3) — *Pharm Monatshefte*, 16 (1935), 123 (H M B)

Racefo Powder (Dr Nussbaum and Co Chem Fabrik, Würzburg) for asthmatic conditions consists of 0.05 Gm the ophyllinethylene diamine 0.05 Gm caffeine 0.0025 Gm agaricinic acid, 0.015 Gm synthetic racemic ephedrine 0.01 Gm extract belladonna and 0.01 Gm dimethylamidopyrazolon in each — *Pharm Monatshefte*, 16 (1935), 123 (H M B)

Reinecke's Blood Regenerator (Fabrik für pharm Spezialitäten Homöopathie und Biochemie G A Reinecke Hannover) is a concentrated extract from the freshly collected leaves

and fruits of the mistletoe *Viscum album* L. manufactured by a special process to protect the natural constituents. It is indicated for use in cases of high blood pressure, vein calcification, aging, headache, vertigo and vasomotor disturbances of the climacteric—*Pharm Zentralh*, 79 (1935), 461 (E V S)

Roba Salts (Walter Bühlner & Co, Bremen 1), contains sodium bicarbonate, magnesium carbonate, calcium phosphate, sodium sulphate, calamus rhizome powdered absinthium and powdered anise. It is used for nervous gastric irritations—*Pharm Zentralh*, 76 (1935), 354 (E V S)

Rugosan Concentrate (Labor pharm diätet Präparate G Breitwieser, Krefeld) an expectorant for bronchitis, is a percolate of castanea, drosera and thyme, saponin (0.5%) and potassium iodide (3%)—*Pharm Zentralh*, 76 (1935), 431 (E V S)

Rugosan Concentrate with Codeine (Labor pharm diätet Präparate G Breitwieser, Krefeld) is a percolate of castanea, drosera and thyme with 0.5% of codeine and ephedrine and 20% of bitter almond water added. It is indicated for coughs, and bronchial and pulmonary asthmas—*Pharm Zentralh*, 76 (1935), 431 (E V S)

Salzschlurfer Pills (Dr W Dernbach, Apotheker, Bad Salzschlurf), a constipation and blood purifying remedy, contain extract of aloe, extract of cascara and *Ipomoea turpethum*—*Pharm Zentralh*, 76 (1935), 354 (E V S)

Sanosin Tablets (Chem Fabrik Perdyamin G m b H, Berlin 027) contain quinine hydrochloride, caffeine, phenacetin and dimethylaminophenazone. It is used for grippe, arthritis, angina and dysmenorrhea pains—*Pharm Zentralh*, 76 (1935), 354 (E V S)

Sanotrapp Herb Extract (Dr Schmidtsche Apotheke, Inhaber Otto Trapp, Tübingen), a blood purifying and an arteriosclerotic preventive, is a percolate of sarsaparilla, tormentilla, angelica, millefolium, gentian, absinthium, crataegus and viscum—*Pharm Zentralh*, 76 (1935), 431 (E V S)

Sapo Liquidis Noury (Noury, Ltd, Deventer) is a liquid soap which is clear at ordinary temperature, foams well and does not irritate the skin. It is used among other things, as a shampoo—*Pharm Weekblad*, 72 (1935), 1045 (E H W)

Scottin (Scott & Bowne G m b H, Pharm Fabrik, Frankfurt a M) is a natural standardized vitamin preparation manufactured from halibut liver oil. Scottin is marketed in pills containing in each 4250 vitamin A units and 250 vitamin D units, and in liquid form containing in each drop 1160 vitamin A units and 70 vitamin D units. They are used for conditions lacking these vitamins such as rickets, osteomalacia, distorted growth of the teeth, and to raise the vitamin A and D content during the lactation period of the mother—*Pharm Zentralh*, 76 (1935), 555 (E V S)

Sediletten Wafers (Cormedia, Chem-pharm Präparate, Mainz) contain in each wafer 0.03 Gm of phenylallylmalonylurea, 0.35 Gm of potassium sodium bromate, 0.05 Gm of quinine hydrochloride, 0.03 Gm of pyrazolone, and a homeopathic dose of phosphorus. It is used as a sedative—*Pharm Zentralh*, 76 (1935), 461 (E V S)

Sedonan (H R Napp, London) consists of 5% solution of phenyldimethylpyrazolon in anhydrous glycerin and is used to reduce pain and diminish inflammation in acute otitis media, otalgia and other inflammatory conditions of the ear—*Drug and Cosmetic Ind*, 37 (1935), 127 (H M B)

Sédospasmodol (Fabrik pharm Präparate Karl Engelhard, Frankfurt a M), an antispasmodic remedy is marketed in cachets and tablets. The cachet contains eumydrin, ephedrine, phenylethylbarbituric acid 0.5 Gm of a bromide, and an easily absorbable calcium salt. They are of use in gall stone colic, bladder spasms, bronchial asthma and dysmenorrhea. In the tablets, the quantities of the spasmolytic and sedative active ingredients are increased—*Pharm Zentralh*, 76 (1935), 431 (E V S)

Sédotyol (Laboratories Debat) is a soothing and antipruritic ointment containing Scuroform 3.75 Gm, benzoic acid 1.25 Gm, Subcutine 1 Gm, zinc oxide 14 Gm, titanium oxide 6 Gm, sodium borate 0.1 Gm, extract of hamamelis 1 Gm. Lanovaseline enough to make 100 Gm—*Bull Ch Synd Pharm Seine* (June 1935), through *J pharm Belg*, 17 (1935), 672 (S W G)

Steegeal Preparations (A L Steege, Leipzig) designated as A, H, M, T (drink cure) are chiefly 10-30% solutions of potash with small additions of liquid petrolatum, volatile oil, camphor

or plant extract Steegonal-Bath is a 30% potash solution with about 1% soap—C. A. ROJAHN and W. BRAUNE *Apoth. Ztg.*, 50 (1935), 815-816 (H. M. B.)

Stomachysatum (Johannes Burger, Ysartfabrik, G. m. b. H., Wernigerode) consists of the extracts of *Artemisia absinthium*, *Achillea millefolium*, *Gnaphalium arvenarium*, *Rheum palmatum*, using the fresh green plants, and is used for dyspepsias, stomach catarrh, disturbed appetites and irregular stools—*Pharm. Monatshefte*, 16 (1935), 123 (H. M. B.)

Sulfigen (Anhaltisches Serum Institut G. m. b. H., Berlin Dessau) is a protected colloidal sulphur preparation containing about 0.13% of sulphur and 0.57% of sulphur dioxide. The antiparasitic containing action justifies its use for scabies, ulcus cruris, eczema psoriasis and fistulas—*Pharm. Zentralh.* 76 (1935), 461 (E. V. S.)

Tablets 111 (Kloster Laboratories Maulbronn) for hyperacidity, heart burn, gastric disturbances, etc., contain extract of condurango bisnuth subnitrate, milk sugar, sodium bicarbonate, heavy magnesium and oil of peppermint—*Pharm. Monatsh.* 16 (1935), 123 (H. M. B.)

Tätsch-Nasol catarrhal preparation (Chem. pharm. Fabrik E. Tätschner, Potsdam) contains benzyl and menthyl esters, dicalcium citrate, and potassium *o*-oxyquinoline sulphate in a viscid solution. Tätsch-Nasol catarrhal solve is similar to the above except that boric acid in glycerin is substituted for the dicalcium citrate. It is marketed in tubes containing a nasal nozzle—*Pharm. Zentralh.* 76 (1935), 432 (E. V. S.)

Thyranon pro injectione (Organon Ltd., Oss) is a thyroid preparation for subcutaneous and intramuscular injection. Each ampul contains 0.2 mg. of combined organic iron and corresponds to 1 tablet of thyranon (100 mg. thyroid powder)—*Pharm. Weekblad*, 72 (1935), 1043 (E. H. W.)

Tonicum Noury (Nourypharma Ltd., Deventer). Each 100 cc. contains 20 Gm. liquid extract of kola, 10 Gm. glycerin, 1 Gm. tincture of nuxvomica, 0.1 Gm. sodium methylarsenate, 0.2 Gm. sacch. manganosus and 3.7 Gm. sodium biphosphate. Dose: 1 teaspoonful three times a day—*Pharm. Weekblad* 72 (1935), 1044 (E. H. W.)

Tonicum Waldheim (A. Waldheim, Vienna) consists of sodium glycerophosphate, sodium methylarsinate, manganese chloride and strychnine nitrate—*Pharm. Post*, 68 (1935), 387 (H. M. B.)

Tordiol (Siemens, reiniger Verfa. Berlin) a roentgen contrast agent, is a 20% colloidal thorium dioxide preparation—*Pharm. Monatsh.* 16 (1935), 123 (H. M. B.)

Tussedat (Sagitta Werk G. m. b. H., München) is a drop preparation containing *Castanea vesca*, drosera, primula, thyme, benzoic acid, some bromide salts and ephedrine (0.35%). A stronger preparation is also available in which the ephedrine is replaced by ethylmorphine (0.8%). It is indicated in pertussis and all coughing conditions of the respiratory tract—*Pharm. Zentralh.* 76 (1935), 555 (E. V. S.)

Trilysin (Promonta G. m. b. H., Hamburg) is a hair water consisting chiefly of an alcoholic solution of cholesterol to which chloroform or carbon tetrachloride has been added in addition to some plant tinctures—*Pharm. Monatshefte* 16 (1935), 139 (H. M. B.)

Urandal Salve (Dr. H. Truttwein, Dresden) is a radioactive iodine uranium salve with 10% iodine and uranium. As bases petrolatum and lard are used—*Pharm. Monatshefte*, 17 (1935), 139 (H. M. B.)

Valvonol (Anhaltischen Serum Institutes, Dessau) is a disinfecting agent consisting of chlororesol, chlorphenol, chlorxylenol and chlorthymol dissolved in a neutral soapy alcoholic and mild base. It is an unusually strong bactericide, non-poisonous, non-irritating and does not attack materials—*Pharm. Monatsh.* 16 (1935), 139 (H. M. B.)

Vinococce (Chem. Werk Dr. Klopfer, Dresden A. 20) preparations are prepared from alcoholic complex colloidal plant extracts concentrated to contain sufficient dosages of the drugs employed. *Vinococci Anticystitici*, a remedy for catarrhal pains of the urinary organs, especially the bladder, contains *Sorbus aucuparia*, *Herniaria glabra*, *Verbena officinalis*, *Fragaria vesca*, *Cochlearia officinalis*, *Betula verucosa*, *Arctostaphylos uva ursi*, *Carex* and *Lanum album*. *Vinococci Antidiabeticum*, a diabetic remedy in all forms and stages, is prepared from *Vaccinium myrtillus*, *Potentilla tormentosa*, *Juniperus communis*, *Taraxacum officinale* and *Rubus fruticosus*. *Vinococci Antiscleroticum*, an arteriosclerotic, gout and rheumatic remedy, contains *Drosera rotundifolia* and *Rosa canina*. *Vinococci Cardiacum*, a heart tonic to increase the power of the heart beat, is prepared from *Crataegus oxyacantha*, *Menyanthes trifolium*, *Nasturtium humulus*, *Allium ursina*,

Marrubium album and *Leonurus cardiaca* *Vinocod Chalcreticum* is prepared from *Capsella bursapastoris*, *Orthosiphon stamineus*, *Cnicus benedictus*, *Alpinia officinarum* and *Gentiana lutea*. It is used against all sicknesses of the gall bladder, the gall duct and the liver. *Vinocod Diureticum*, a dropsy remedy in all forms, stages and appearances, is prepared from *Ononis spinosa*, *Petroselinum sativum*, *Levisticum officinale*, *Bryonia alba*, *rosmarinus* and *Phaseolus vulgaris*. *Vinocod Lactagagum* is prepared from *Ancithum graveolens*, *Galega officinalis*, *Polygala amara* and *Carcx arcuaria*. It is indicated for deficient milk excretion in the nursing mother. *Vinocod Nephriticum* is prepared from *Lanum album*, *Polygon avicul*, *Acorus calamus*, *Solidago virgaurea*, *Geranium Robert*, *uva ursi* and *Borago off*. It is used for nephritis, renal contractions and bleeding. *Vinocod Pectorans*, a remedy for pains of the lungs, for bronchitis, pertussis, grippe, etc., is prepared from *Levisticum officinale*, *Tussilago farfara*, *Inula helenium*, *Thymus vulgaris*, *Plantago lanceolata* and *verbascum*. *Vinocod Phthisicum*, a remedy for all stages and forms of tuberculosis is prepared from *Achillea millefolium*, *Pulmonaria officinalis*, *Galeopsis achroleuca* and *inula*. *Vinocod Spasmolyticum* is prepared from *Matricaria chamomilla*, *Achillea millefolium*, *Mentha piperita* and *Gentiana lutea*. It is used for cramps of various origins, especially the gastric and digestive organs. *Vinocod Uterinum* is prepared from *Polygonum hydropiper*, *Crataegus oxyantha*, *Alchemilla vulgaris*, *Rhamnus frangula*, *Achillea millefolium* and *Matricaria chamomilla*. It is indicated for acute and chronic types of dysmenorrhea, climacteric maladies, etc.—*Pharm Zentrall*, 76 (1935), 380 (E V S)

Vistonic Syrup (Laboratory Farmacol Reggiano, Corregio, Italy) is a combination of copper-chlorophyll, iron and manganese glycerophosphate, quinine, caffeine and extract of nuxvomica marketed in packages containing 115 Gm. and in packages of 20 tablets (each tablet = 0.0025 Gm. of the extract)—*Pharm. Post*, 68 (1935), 327 (H M B)

PHARMACEUTICAL ABSTRACTS

INDEX OF AUTHORS

A

- Abdulkadir Luft toxicity of castor beans 101
 Abelin I, assay of various preparations of thyroid 189
 Ahlgaard J reactions of solutions of novocaine on sterilization and storage 48
 Ahramowitz I W reactions caused by phenyl pbthalein 251
 Aht A F use of ascorbic acid (ascorbic acid) in the treatment of infantile scurvy 34
 Acevedo B S pregnancy diagnosis 164
 Adams R introduction of isobutyl groups into phenols cresols and homologous compounds 7
 Addinall C R sex hormones II estrus producing hormones 202
 contributions of medicinal chemistry 205
 sex hormones I hormones of the anterior hypophysis 116
 Adnot Mme distillation of aromatic waters for determination of volatile constituent 9
 Aeschlimann J A synthesis of new medicinal alkaloids 157
 Ahlm T rhizome and extract of male fern 188
 Alber H K improvements in microchemical laboratory technique 307
 Albers C C value of botany course as a foundation for the pharmacognosy of stem and bark drugs 135
 Alexander G H sedatives types uses and dangers 87
 Allard J study of citronellol rhodinol isomerism by means of raman spectrography 208
 Allen, W M inhibition of uterine motility with crystal line progesterin *in vivo* 339
 Allport N L deterioration of atropine eye ointments on storage 310
 Alpers H morphine habituation withdrawal cure with quinine 350
 Amador R S ratio between effective and lethal doses of bulboecapnine in the cat 242
 Ambroz W F pharmacist and the podiatrist 335
 Ammerman M studies of crystalline vitamin B IV injection method of assay 248
 Amy L new apparatus for measuring ultraviolet absorption 316
 Anderson A C differentiation of vitamin A from carotene by means of antimony trichloride 130
 Anderson E M studies on the thyrotropic hormone of anterior pituitary 112
 Anderson H P some organic mercurials 154
 Andrews J action of morphine as a metabolic stimulant 244
 Andrews M J determination of reasonable or permissible margin of error in dispensing II ointments 79
 margin of error in dispensing Determination of the reasonable or permissible margin of error V liquids 236
 Andrieu G skin reaction of diphtheria toxin 270
 Anger F V application of spot reactions to detection of organic compounds 127
 Angia B characteristics of 1934 Algerian geranium oil 104
 Anselme E use of protosil in puerperal fever 195
 Anselme C acid indices of official oils and waxes lime liniment of the Belgian Pharmacopoeia IV 214
 Ansingh E Q behavior of various acids toward quinine tannate 102
 Antoine G determination of colloidal silver in organic medicinals application to ointments 166
 Appel H improved method for the synthesis of coumarins by v Pechmann's method 286
 Arend A G Nail polishes and enamels 133
 grease paints 234
 lip stick 76
 manufacture of hair dyes 234
 Arnal Y sensitive reagent for aluminum separation of aluminum and beryllium 216
 Arnold F W Jr use of α propylarsonic acid as a reagent for the determination of zirconium 16
 Arnolt R L alkaloids of *Cereus coryne* 157
 Arquet M solubility of phenylethylbarbituric acid in ether 311
 Ashe W F Jr blood sugar changes after 1-2-4 dinitrophenol 138
 Ashimoto A on the constituents of *Hydrangea paniculata* and on hydrangen 284
 Atkins F classification of commercial ylang oils 274
 Aub J C biochemical behavior of lead in body 31

- Audier H volumetric determination of arsenates 210
 August S β aminophenol hydrochloride as a reagent for cupric and ferric ions 120
 microchemical of iodide ion 124
 micro reaction of chromium pigment 119
 systematic method for the identification of mineral pigments 11, blue and green pigments 308
 systematic method for microchemical identification of mineral pigments 125
 Augustin J soaps and soap substitutes in tooth preparations 179
 brushless shaving creams 326
 lanolin and its uses 235

B

- Bachrach R L synthesis of perfumes preparation of methylene ester of pyrocatechol 112
 Badzynski St adsorption charcoal prepared from corncellulose 110
 Baert C G anesthetics with special reference to cocaine and novocaine in illegal trade 295
 special detection of cocaine and novocaine anesthetics with reference to smuggled goods 8
 Bagchi K N method for the colorimetric determination of small quantities of iodide in the presence of other halides 13
 Baggesgaard Rasmussen H solubility of morphine in different solvents 102
 Bailey K C decomposition of hydrogen peroxide in presence of glass wool and copper sulphate 274
 Bailey O orthophosphoric acid migration phenomenon in the course of hydrolysis of the three mixed diesters 275
 Bailey R H control of whooping cough with serum and vaccine 273
 Bain J surgical dressings criticism of some of the codex standards 224
 criticisms of some codex standards for surgical dressings 325
 Bajewski-Sowet use of gonococcus vaccine in acute gonorrhea 348
 Baker A B latent tuberculosis antitoxins 98
 Baker G L solubility of some strychnine benzoates 159
 Balansand J constituents of the rhizome of *Cimicifuga racemosa* 162
 Baldinger L H continuous reading titration apparatus 10
 suggested formula for white liniment 78
 Baldini C cosmetic pomade 233
 Balzarelli F cosmetic pomade 233
 Bamhach K stability of diethane solution II 120
 volumetric determinations of balides use of di chlorofluorescein as an adsorption indicator 220
 Bandoni A J garlic and its preparations 91
 Banks A composition of commercial palm oils IV progressive hydrogenation as an aid in the study of glyceride structure 106
 Banks N S Ferry's meningococcus antitoxin 97
 Barbour F A respiratory effects of morphine codeine and related substances III effect of morphine dihydromorphine dihydromorphine (dilaudid) and dihydrocodeinone (dicodid) on respiratory activity of rabbit 30
 Barbour H G action of morphine as a metabolic stimulant 244
 effects of phenacetin and aspirin respectively upon action of phenobarbital 245
 Barger G alkaloids of senecio 208
 Bari Z influence of method of preparation of nitroglycerin tablets on nitroglycerin content 73
 evaluation of tinctures made according to six different procedures 73
 Barkenhuis C oil of rose mallow seed 107
 Barlow O W relative efficacy of a series of analeptics as antidotes to sublethal and lethal doses of pentobarbital chloral hydrate and avertin 338
 Barowsky H investigation of the new biologic test for hormones in pregnancy urine 290
 Barsch H separatory funnel 314
 Bartholomew R A advantages of paraldehyde as basic anesthetic agent in obstetrics 36
 Bartz Q R introduction of isobutyl groups into phenols cresols and homologous compounds 7
 Bassett H solubility and determination of calcium hydroxide 218
 Bateman F C L alcohol content and specific gravities of tinctures of B P C 1934 324

- Batterman R C reaction at site of injection of mercurial diuretics as influenced by theophylline 250
- Bauer K H evaluation of drug plants in 1934 205
- Bauer O vitamin synthesis 104
- Bauke L E clinical studies with intestinal and parenteral administration of diglucan 193
- Baumgarten G determination of oil of peppermint 310
- Baxter G P fifth report of committee on atomic weights of the International Union of Chemistry 156
- Bozille M S importance of fluorinated methemoglobin in the determination of fluorine in industrial hygiene 224
- Boel G D activated charcoal 299
- Boel J H Pharmacopoeia of the U S and the Federal Food and Drugs Act 374
- Beoune A biological estimation of male hormone upon the hordend 244
- Becker S Jugoslavian opium 226
- Beerman H *et al* dioxoanthracinol 18 n substitute for chrysorin 35
- Begg N D value of insulin in toxic diptheria 91
- Beguin C investigation of some species of honey suckle 283
- hygroscopicity of dried extracts of the new Swiss Pharmacopoeia 320
- Behr G dentifrices 233
- Belknap E L control of lead poisoning in workers 32
- Bell M L absorption of carotene and vitamin A 239
- Bendo L therapeutic dye solutions 193
- Bender L E treatment of chloro with nivalol 36
- Beonett C T melting point of chloroformamide 300
- alcohol content and specific gravities of tinctures of B P C 1934 324
- Benoit G chemical and physiological study of omnes and diomines with ethylene grouping 54
- Berg B N blood sugar curves in normal and diabetic dogs after intravenous injections of insulin 139
- Bergstrom F W metabolic activity of compounds related to dimetrophenol 28
- Berry H preparation of digitalis tincture relative merits of maceration and percolation 320
- hydrogen ion concentration of injections 124
- pharmaceutical aspects of British Pharmacopoeia Codex 1934 73
- Berry F A revision notes on British Pharmacopoeia 133
- Bertonasco E proportion of digitoxin in digitolis 274
- digitoxin content of digitalis purpurea 283
- Beutler R determination of cane sugar content of small volumes of solutions from specific gravity and specific rotation 10
- Bhattacharya R constitution of loc 112
- Bidwell E H effect of nembutal upon serum cholesterol of dogs 188
- Bien G E differential reactions between carotene and oils rich in vitamin A 130
- Bieter R N spinal anesthesia in the rabbit therapeutic coefficients 247
- Boylsma U G report of the investigation of East Indian digitalis leaf 70
- Bing F C method for the estimation of serum iron 116
- Binger M W diuretic action of potassium salts 246
- Binet L food value and anti anemic power of oysters 139
- Binkert A β - iodohydroxy naphthalenedisulphonic acids 56
- Birch C A methyl chloride poisoning 89
- Birza J W examination of copaiba balsam 64
- Biscaro G Italian and Hungarian matricaria 205
- Blakeslee A F fertilization of Datura stromonium and D metel in the incompatible cross 204
- Bland J O W growth and development of psittacosis virus in tissue cultures 155
- Blazek Z scheme for microscopic examination of drugs 70
- derivatives of n phenyl piperazine 286
- Blench R O suggested test for distinguishing between meat extract and yeast extract 14
- Bliss A R Jr children's tooth pastes 77
- comparative study of the absorbability of calcium compounds 137
- opium comparison of proposed methods 222
- tannic and picric acid in burns 352
- trichophytosis 353
- Block E compositions for use as vehicles for other substances 237
- Block J compositions for use as vehicles for other substances 237
- Block C J native poisonings in the Dutch Indies 89
- Mount B K veratrine alkaloids, parts I and II, 169
- Blumenthal H B colorimetric titration of small amounts of iron by means of α - α dipyridyl as indicator 305
- Boer P note on mercury pill B P 1932 247
- Boam J J determination of rotenone in derris root and resin 88
- constituents of derris resin 55
- Böhm R, action of substances isolated from croton oil 184
- Bogen F studies of correlated human and bovine brucellae 153
- Boltanski I Lugol's solution 175
- Bolz N O regeneration of glycerin in production of glycerophosphates 56
- Bonsdorff R toxic reactions of amidopyrine 249
- Bose A C method for the determination of small quantity of iodide in the presence of other halides 13
- Bose M K estimation of zinc in the presence of iron aluminum uranium beryllium and titanium 316
- quinaldine used as a micro reagent 1 estimation of zinc and its separation from manganese 127
- Boseki K K glyceroluril 101
- Bougault J reaction for the identification and determination of citrol 169
- silver mercury complex 275
- Bowen J I storage of drugs new problems in drugs 228
- Bowers H R analysis of magnesium carbonate 66
- Brocaloni L new method for the quantitative determination of quinine iodobismuthate 312
- Bracco L ultrafiltration and its application to the extraction of the active principles of plants, 230
- Braceland F G use of hematoporphyrin as a therapeutic agent in psychosis 118
- Brolim C separation of hormones and lipids 114
- Braker W phenyl procaine local anesthetics 109
- sulphide analogues of azo dyes having bactericidal properties 345
- Bramwell B R gastric secretion 111
- Brondrup W fluidextract of thyme and its preparations 174
- preparation of dry extract of belladonna 322
- Bronhm S L protection of mice against meningococcal infection by polyvalent meningococcal serum 268
- Brord D toxicological study of some chromium compounds 31
- Broun L ontological investigation of the leaves of Polyodiaceae of pharmacological interest 156
- Bravo I some effects of alphi-dimetrophenol on pregnancy in white rat 83
- Brew M value of tolu coating U S P X and N F V 133
- Brewer R K body temperature changes produced by sodium salts of some oromotic acids 84
- Briggs D R physicochemical studies on osazo solutions III osmotic pressures of solutions of orotic acid and sodium arabate 156
- Briggs W P theory of pharmacy and academic standards 81
- Brinzinger H cellophone and luprophone as diolysis membranes 218
- Brocol M M chemical study of Sierra Nevada digitalis 21
- Brodie M active immunization against poliomyelitis 40
- active immunization against poliomyelitis with germicidally inactive virus 46
- convalescent serum in poliomyelitis 154
- Brown A poisoning of children by strychnine 90
- Brown C L M note on isopropyl nitrite 286
- some properties of glycols with special reference to the use of propylene glycol as a solvent in pharmaceutical preparations 323
- Brown F contribution to pharmacology of nicotine 245
- Brown H W anthelmintic studies on alkylhydroxy benzenes III 6 n alkyl meta cresols 27
- anthelmintic studies on alkylhydroxybenzenes I alkylpolyhydroxybenzenes 27
- oral toxicity of 6 alkyl meta cresols 83
- Bruce W F growth of bacteria in organic acid medium 2
- Brugsch T cinchophen (atophan) therapy and the liver 346
- Brundage J T comparative study of actions of morphine and diloidid (dihydromorphinone hydrochloride) on intact small intestine of dog 30
- action of opomorphine upon small intestine in non anesthetized dogs 84

- Bruno F Cymhopogon flexuosus Stapf and Cymhopogon martinii Stapf var Motia oils 102
- Brus G study of citronellol rhodinol isomerism by means of ramán spectrography 208
- Bruse W I preheater for the microanalytic determination of carbon and hydrogen 209
- Bryan H F action of mercurial antiseptics on muscle oxydase 188
- Bryant W M D aldehydes and ketones improved hydroxylamine method for determination of displacement of oxime equilibria by means of pyridine 8
- Bryce D A medicinal dyes 110
- Bucchi bakelite containers 235
- Buchi apparatus for the preparation of sterile distilled water 320
- Buchi J stability of spiritus sinapis Swiss Phar V 176
- Buchman I R studies of crystalline vitamin B₁ VIII sulphite cleavage II chemistry of the acidic product 104
- studies of crystalline vitamin B₁ cleavage of vitamin with sulphite 61
- Buchner A pharmaceutical emulsions 321
- Buck J S relative anesthetic effects of various ureas 248
- Büchi bokelite ointment jms 180
- Buell M F seed and seedling of Acorus calamus 204
- Bukey I S value of tolu coating U S P A and N I V 133
- comparative study of enteric coatings 347
- Bull A W percolation of cinchona and belladonna rate of alkaloidal extraction and effect of degree of comminution 310
- Bullock B volumetric microdeterminations of chloride and potassium ions 218
- Bullock K assay processes and stability of commercial pepsin 170
- Bunney W F use of wax paraffin ampuls for silver nitrate used in prevention of ophthalmia neonatorum 324
- use of intradermal injections of toxin toxoid mixtures 153
- Burckhardt E stable solutions of calcium gluconate 55
- ergohesine new water soluble alkaloid of ergot 200
- Burger A M sage oil in perfumery and cosmetics 179
- Burbans R A experience with gonococcus filtrate in treatment of gonorrhea 2
- Burker E S new spot reaction for cesium 209
- Burfage H M theory of pharmacy and academic standards 81
- comparison of four year curricula in pharmacy 80
- Burn J H isolation of ergometrine 200
- Burskirk H H Aerobacter aerogenes as cause of rotiness in maple syrup 52
- Butler C L value of cinchona alkaloids in pneumonia miscellaneous alkaloids and some hydrocupreine ethers 85
- pneumococcal value of cinchona alkaloids 111
- apocupreines (apocuprine) 153
- Butler M R some properties of polysaccharide complex from Chondrus crispus 3
- C
- Cahn R S constituents of derris resin 55
- determination of rotenone in derris root and resin 68
- pirotoxin part I 287
- Calderone F A studies on dosage of pre-anesthetic medication with narcotics (barbiturates, morphine, sodium sulphate and morphine) 337
- Caldwell J R iodometric determination of copper 11
- modified Volhard method for determination of chloride 10
- Callahan E T haeteriostatic action of skatole on Gram negative enteric bacilli 272
- Callister C P preparation of liver extract 115
- Campbell D treatment of parathyroid tetany 92
- Campbell N R melting point of chloral formamide 300
- Canti R G growth and development of psittacosis virus in tissue cultures 155
- Carelli A value of sodium wheyolate in the treatment of some diseases caused by a filtrable virus 351
- Carlson H E effect of morphine on human ureter 188

INDEX OF SUBJECTS

A

- A B D capsules 37
 Acheson's composition of etheral oil of 278
 Absorbent medicine for internal use 254
 Abscessin 355
 Adhūm capsules 197
 Aeno 20
 effect of intravenous injections of on physico chemical properties of blood 82
 identification reactions for 12
 mucilage of and detection of oxidase in 13
 solutions physicochemical studies on 111
 osmotic pressures of solutions of arabic acid and sodium nitrate 150
 Acecolex 254
 Acetanilid ratio of toxicity of to its antipyretic activity in rats 240
 stabilization of hydrogen peroxide especially by 174
 Acetanilide poisoning clinical and experimental study of 191
 Acetearhamol 37
 Acetic acid detection of by formation of indigo 170
 Acetone n butanol and ethanol analysis of in aqueous solution 214
 Acetonitrile test for thyroid 180
 Acetyl beta methylethanol action of on ventricular rhythms induced by adrenaline 183
 chloride use of in treatment of neurogenic bladder and allied conditions 34
 Acetylcholine effects of on gastro intestinal motility in normal dogs 80
 value of in ophthalmology 90
 Acetylsalicylates decomposition of 214
 Achilles millefolium Linné volatile oil of 4 160
 Acid uric elimination of from rats liver by action of cinchophen and tolysin 28
 indices of official oils and waxes lime liniment of the Belgian Pharmacopoeia 214
 Acids aromatic body temperature changes produced by sodium salts of some 84
 Acids organic assay methods for salts of 17
 Acidum acetum 54
 Acimo analysis of 62
 Acne quantitative estimates of hydrogen sulphide in lotions used in treatment of 13
 Aconite chemical composition and physiological assay of 82
 dispart 37
 root detection ofaconitine in 8
 Aconitine detection of in aconite root 8
 Aconitum napellus extract of chemical composition and physiological assay of aconite 82
 Acorus calamus seed and seedling of 204
 Acriflavine emulsion simple formula for 179
 Activated charcoal 299
 Adephelen 325
 Aderal 37 197
 Adexoline 93
 Adhesive plaster irritants in 240
 plasters lesions produced by and method of determining adhesive power 62
 Adiposettes 38
 Adiponitron 355
 Adonidin minimum emetic dose with 183
 Adonis vernalis method of extracting active principles of 282
 Adormine tablets 38
 Adrenal cortex hormone effect of on hypertension and on cardiovascular system 34
 Adrenalin 207
 action of acetyl beta methylethanol on ventricular rhythms induced by 183
 inhalation of for the relief of asthma 343
 Advertising place of a field representative in cooperative profession 81
 Aecuferrulstrapp with manganese 94
 Aesulus turgidatus hume saponin of the seed of 282
 Aggranulocytosis due to dimidopyrin 30
 Agrypnal nmpuls 38
 Albion 38
 Albumin tannat 294
 Alenhal attempts to modify the concentration of in the blood after intravenous administration of 240
 concentration of when stored in wadded vessels 226
 detection of benzene in 217
 determination of in tinctures 215
 extent of absorption of at intervals after oral administration 183
 injected intravenously effect of habituation to rate of metabolism 336
 Alcoholism experimental studies in IV attempts to modify the concentration of alcohol in the blood after intravenous administration of alcohol 240
 Alcohols estimation of in essential oils 64
 Aldehydes and ketones improved hydrxylamine method for determination of displacement of oxime equilibrium by means of pyridine 8
 Aletermich 38
 Algolin tablets 142
 Alkaloid containing poisonous drugs detection of in powdered drugs 294
 Alkoloidal drug extracts the air lift extractor applied to the analysis of 117
 salts estimation of by direct titration of their acid radicals 215
 salts titration of use of porrier blue as indicator 117
 Alkaloids determination of application of the mercurimetric method in new biological products 215
 determination of in injectable solutions 294
 distribution of in different parts of central nervous system and their quantitative microdetermination in tissues 11
 fat water solubility coefficient of 242
 of succineous plants pharmacological action of 11
 caryidine 330
 quantitative determination of with bromine 118
 rotatory power of various 295
 synthesis of new medicinal 157
 Alkonon microchemical detection of magnesium and aluminum with and naphthazarin 168
 Alkoxy benzamides substituted 92
 Alkoxy cumorins relation between odor and constitution in the case of 162
 Alkylhydroxybenzenes onthelmintic studies on 1,
 alkylpolyhydroxybenzenes 27
 onthelmintic studies on 11 ortho and para
 alkylphenols 27
 onthelmintic studies on 111 6 n alkyl meta cresols 27
 oral toxicity of 83
 5 5 Alkylphenylbarbituric acids synthesis of 6
 Alkylpolyhydroxy benzenes onthelmintic studies on 27
 Allergy 343
 Alletan 94
 Allipropion tablets 38
 Allium contribution to the determination of preparations of 241
 Allinam 94
 Allotann 38 197
 Allyarsin 94
 Allylpropynol 38
 Alne evaluation of 20
 Alon examination of three samples of 215
 Alonin 254
 Alpecine oil 94
 Alpha amylase determination of 215
 diminution of cresol toxic reaction in 340
 dinitrophenol some effects of on pregnancy in white rat 83
 isomorphines hydrogenation of 3
 Althea leaves and root evaluation of 226
 Aluminum estimation of zinc in presence of 316
 acetate dispart 38
 and magnesium microchemical detection of with alkonon and naphthazarin 168
 sensitive reagent for separation of aluminum and beryllium 216
 subacetate molecular solubility of 274
 A M O antiseptic solution 355
 Amhinon 142 355
 Amebiasis observations on antigens for complement fixation in 140
 Amide nitrogen determination of in plant tissue 216
 Amidopyrin agranulocytosis due to 30
 Amidopyrine detoxification of by sodium amygdal 192
 and dinitrophenol (2 4) detection of 8
 effect of on leucocyte count 183
 inhibition of leucocyte activity in rabbit by certain

- cyclic compounds, 83
toxic reactions of 249
- Amidopyrine and amytal effect of on blood picture of the albino rat after a deficient diet 336
- Amine salts of antimonie and benzenesthionic acids 54
- Amines and diamines with ethylene grouping chemical and physiological study of 54
- 2 Aminolenzimazole structure and derivatives of 54
- p* Aminobenzoic acid determination of esters of 118
- Aminogen 254
- p* Aminophenol hydrochloride use of as a reagent for cupric and ferric ions 120
- 8 Aminoquinoline derivatives of as antimalarials IV 252
- Ammonia determination of 62
and amide nitrogen determination of in plant tissue 210
- Ammonium nurothiosulphates preparation and properties of 6
molybdate use of as a microchemical reagent 164
- Amos throat water 355
- Amphopulmon ampuls 143
- Amphyl 143
- Amyl nitrite use of in cases of contraction ring 252
- Amylolytic activity determination of in pancreatin 15
- Amytal effect of upon pilocarpine induced submaxillary and gastric secretion 183
and amidopyrine effect of on blood picture of the albino rat after a deficient diet 336
- Analeptin preparation and chemical composition of synthetic 142
- Analytical methods notes on some with special reference to their teaching value 118
- Androcalcon H 254
- Androsterone clarification of constitution of 116
- Androstina 38
- Anesthetic new 90
- Anesthetic properties of trichlorethylene study of the 340
- Anesthetics some colored local 100
local testing of by sciatic nerve block in guinea pig 83
special detection of cocaine and novocaine with reference to smuggled goods 8
special reference to cocaine and novocaine in illegal trade 295
- Angina pectoris value of strophanthin in 92
- Anginal tablets 38
- Angostura bark 70
- Anhydron value of as drying agent 3
- Animal charcoal pills 143
tissues determination of total lipid in plant tissues and 14
- Aniseed oil preliminary report on study of from Kuangsi 208
- Anox 197
- Antacid preparations 178
- Antagosan 255
- Antagosa 355
- Anterior hypophysis hormones of the 116
pituitary clinical manifestations of dysfunction of 57
pituitary general physiology of 57
pituitary growth hormone of 289
pituitary studies on the thyrotropic hormone of 112
pituitary extract 255
pituitary and anterior pituitary like substances 289
thyrotropic hormone separation of of pituitary 59
- Antetestin 355
- Anthracin 355
- Anthracene oils use of for the defence of crops 273
- Anthranic acid microdetermination of zinc by means of 317
- Anthrex suppositories 355
- Anti cholera serum treatment of cholera with new 2
- Antidotes I general plan 31
- Antigilda 197
- Antimalarial drugs of natural origin 343
- Antimalarials derivatives of 8 aminoquinoline as IV 252
- Antimeningococcal serum a method for titrating the protective action of 152
- Antimeningococcal serum protection of mice against meningococcus infection by polyvalent 268
- Antimeningococcus serum notes on the concentration and purification of 96
- Antimonie acid amine salts of and benzenesthionic acid 54
- Antimony compounds complex pentavalent with aromatic polyhydroxy compounds 55
compounds therapeutic bactericidal and antiparasitic organic 93
- content in drugs consideration of the used for destruction of schistosomes 344
- trichloride differentiation of vitamin A from carotene by means of antimony trichloride 130
- Antiparalysis serum one hundred per cent effective ness with 45
- Antipneumococcal serum a new method of titration of by the neutralization of the antibodies *in vitro* 203
- Antipholomyelitis serum virus adsorbed to alumina gel for production of in sheep 45
- Antipyretics 252
- Antipyrine contribution to the microchemistry of 216
- Antistreptococcal serum 152
- Antistreptococcal serums application to of a new method of titration by neutralization of the antibodies *in vitro* 208
- Antitoxic serum new method of treatment of diphtheria with 45
- Antityphoid sera virulence tests for typhoid bacilli and antibody relationships in 152
serum new 06
- Antryol 143
- Antutrin S 255
- Apocosan N 197
- Apol detection and determination of in viscera 131
pharmacologic tests of 83
- A P L 254
- Aploxa 38
- Apocrepines pneumococcal value of 153
- Apomorphine action of upon small intestine in non anesthetized dogs 84
hydrochloride preparation of for injection 235
- Apoquinine 206
- Apoquinine pneumococcal value of 153
and apoquinidine 206
- Apothecaries in Landau (Pfalz) history of the 322
of the city of Königsberg history of the The Adler Apothecary 332
of the Hague 237
- Apothecary of the Golden Eagle in Landburg on the Warther history of the 332
- Apothyrin dragees 354
- Apparatus titration continuous reading 19
- Aquiox 143
- Aquidrine 197
- Aquidrine osmotic pressures of solutions of and sodium arbate 156
- Argyrol collargol electargol and protargol reactions for the differentiation of 290
identification of 121
- Argyrophedrine 355
- Arojeol 197
- Aromatic acids body temperature changes produced by sodium salts of some 84
waters distillation of for determination of volatile constituent 9
- Aromatics noteworthy new special 278
and volatile oils advances in the field of in 1933 ketones 102
- Arsacetum 255
- Arsanilic acid N (*p* dimethylaminobenzal) chemical therapeutic testing of 90
- Arsenamides compounds containing the As N linkage 211
- Arsenates volumetric determination of 216
- Arseneten 38
- Arsenic determination of in tonicum 128
organic compounds of 56
presence of in bismuth preparations 19
quantitative determination of small amounts of 217
triple poisoning by 172
- Arsenical Fowler Solution 235
- Arsenicals K 324 and K 352 trypanocidal action of on infections in mice and rabbits 336
- Arsenobenzene derivatives assay of several 165
- Arsenobenzene chemical examination of 217
- Arsine poisoning by 249
- Arsphenamine 162
ocular reactions due to 249
poisoning occurrence of among negro women 341
- Artemisia new crystalline principles from Indian 20
- Rigida (Nutt.) Gray oils of 160
- Arthrorheum 356
- Ascaric fluid partition of phenol between olive oil and serum in 164
- Ascorbic acid (vitamin C) comparison of oral and subcutaneous administration of protective doses of 241
acid inactivation of diphtheria toxin *in vivo* and *in vitro* by crystalline 153
acid influence of on sensitization of guinea pigs to neoarsphenamine 84
acid sensitive spot reaction for 118

- acid total content of human blood method of determination 113
 acid (cevitamic acid) use of in the treatment of infantile scurvy 34
 Askaridol dragees 107
 Aspergillus niger action of aqueous extracts of drug plants on 270
 Aspirin effects of phenacetin and respectively upon action of plicnabarbitol 245
 Astringent lotions 74
 Atabrin 254
 Athletic sweat, 344
 Atomic weights committee an fifth report of the International Union of Chemistry 160
 Atophan poisoning 191
 (cinchophen) therapy and the liver 340
 Atropine action of on reanimation of heart in secordary chloroform syncope 240
 distribution of in different parts of central nervous system and their quantitative microdetermination in tissues 241
 eye ointments deterioration of an storage 319
 group homeopathic tinctures of 71
 study of commercial drugs containing 206
 Auratherapy dangers in 249
 Avertin pentobarbital and chloral hydrate relative efficacy of a series of anaesthetics as antides to sublethal and lethal doses of 338
 onesthesia treatment of tetanus with 344
 Azo dyes sulphide analogues of having bactericidal properties 345
 Azochloramid 354
 bacterial action of 45
 use of in root canal antiseptics 345
 Azonle colicum L-B 356
 Azulene sesquiterpenes enlar content of 206
- B
- Bacillary dysentery cause of in infants and children 96
 Bacterio growth of in organic acid media 2
 in water samples effect of temperature of storage on 152
 Bacteriol cells microscopic method of distinguishing dead from living 268
 Bacteriophage nature of formalin inactivation of 152
 use of in the treatment of urinary infections 209
 I studies on the nature of 208
 II studies on the nature of 269
 Bacterium coli action of aqueous extracts of drug plants on 270
 typhiflorum study of the so called 269
 Badianus manuscript on Aztec pharmacopoeia 332
 Bakelite containers 235
 Baldrast 197 255
 cum Nitro 197
 Balsam of Peru hypersensitivity of skin to 88
 Barbitals titration of with silver nitrate 9
 Barbiturates sex difference in white rat in tolerance to certain 84
 and strychnine elimination of 189
 Barbituric acid derivatives determination of in urine 212
 Bath preparations XIV 206
 XV, foot baths 297
 Bedsores treatment of 345
 Beechwood lignin product of reaction of carbohydrates in the determination of 59
 Belgian pharmacopoeia IV same remarks on 24
 Belladonna percolation of 319
 dispers 38
 rat the effect of fineness of powder and of variation in solvents on the percolation of 227
 root function of preliminary maceration in relation to the percolation of 329
 Bellergal 38 143
 Bellier number study of its use for the detection of peanut oil in olive oils 297
 Benedict's test modification of 212
 Benzaldehyde determination of small quantities of chlorine in commercial 9
 Benzene detection of in alcohol 217
 experimental research on the toxicity of the vapors of 250
 ultra violet absorption spectrum of 297
 Benzenethiamic acid amine salts of antimanic acid and 54
 Benzofurquinolines 109
 Benzoin and cinnamic acids identification of in microsubstances of balsams and resins 297
 Benzylphenidrine use of as analgesic in chaulmoogra injections 34
 Beryllium estimation of zinc in presence of 316
 separation of aluminum and 216
 Beta carotene analysis of, and leaf xanthophyll in thirteen plant tissues 10
 isomerides hydrogenation of 3
 Bevitane 197
 Bihrafluor 93
 Bichloride of mercury quantitative study of renal injury in case of acute poisoning by 250
 Bichromate skin sensitivity to 183
 Bickmarin 197
 Bile salts influence of on the nervous system following intraspinal usage 136
 Bilirubin Van der Bergh reaction of variations in xanthochromic cerebrospinal fluid 69
 Binman 356
 Biochemistry inorganic nature on 289
 Biocholine 255
 Biology for pharmaceutical students 334
 Biotalc 38
 3,3' Bis (ozometa phenylenediamine) 4,4' dihydroxyarsenabenzene and 3,3' bis (azo 2,6 diamminopyridine) - 4,4' dihydroxyarsenobenzene preparation and properties of 211
 Biseptol 255
 Bism kaolin 255
 Bismurug 255
 Bismuth assay of medicinal pharmaceutical preparations containing 298
 leicrins on injectable preparation of 241
 poisoning pharmacodynamics and toxicology of bismuth 341
 presence of arsenic in preparations of 19
 violet use of in malaria and far chancroids 34
 Bisteril breili 197
 Bix ocellana L analysis and therapeutic action of 29
 Black mint peppermint nilram cultivated in southern Sweden 161
 Bleaching powder determination of manganese in 108
 Bismal 39 197
 Blood attempts to modify the concentration of alcohol in the after intravenous administration of alcohol 249
 alcohol relation of intoxication in man 241
 effect of intravenous injections of alcohol on physiological properties of 82
 iron methods for determining comparison of wet and dry osing 57
 relation of calcium to formation of 140
 serum determination of indoxyl content of 292
 sugar and vegetable extracts 199
 total ascorbic acid content of human method of determination 113
 urea estimation of 289
 volumetric determination of sugar in 292
 Boiling point relation of and vapor pressure to the composition of glycol water mixtures 3
 Bokonal 259
 Bone phosphatase activity of in chronic fluorine poisoning 241
 Borax and sulphur in cosmetic preparations 74
 glycerin water solutions reactions of, 298
 Borhamyl 356
 Boric acid skin disturbances through the use of defatting agents containing 191
 acid containing fat reducers 88
 acid preparations toxicity of skin disturbances through the use of defatting agents containing boric acid 191
 Botany course value of as a foundation for the pharmacognosy of stem and bark drugs 155
 Brazilian euphorbiaceae essential oils from 204
 flora myriatic and myriatic from 273
 B R I collard 255
 Brilliant green value of as a local antiseptic 153
 British Pharmacopoeial Codex 1934 73 178
 Pharmacopoeial Codex 1934 medical aspects of 73
 Pharmacopoeial Codex 1934 pharmaceutical aspects of 73
 Pharmacopoeial Codex review of 73
 Pharmacopoeia revision notes on 133
 Pharmacopoeia scheme for the identification of the simple liquid preparations of the 125
 Bracanal 39 94 198
 Bromides detection of small quantities of in sodium chloride 298
 determination of small amounts of in sodium chloride 62
 tatic reactions of 2,0
 Bromide electrometric determination of in the presence of large amounts of chlorine 298
 quantitative determination of alkalis with 118
 Bromatanturan 259
 Bromural and veranal fusao curves of 98

Branchavaydrin aintment 143
 Brucella abortus toxic principles of 1, preporation
 toxicity and biochemical nature of alcoholic
 precipitate 53
 Brucellasis studies of correlated human and baviné
 153
 Brucine and strychnine part 277
 Brushless shaving creams 326
 Bulbacapnine ratia between effective and lethal doses
 af in the cat 242
 Bupleurum falcatum L. constituents of roots af 284
 Burns 34
 preparations for 326
 Butanol, analysis af in aqueous solution 214
 Butterfat determination of in food 298

C

Cadmium estimation of copper and its separation
 from manganese nickel cobalt etc 120
 Coesium new spat reaction for 299
 Caffeine coffee and decaffeinated coffee effect of
 upon blood pressure pulse rate and simple reac-
 tion time af men of various ages 183
 and theobramine effect of upon digitols toxicity
 191
 content af, in decaffeinated coffees and value of
 decaffeinated coffees in nutrition 63
 determination of in decaffeinated coffees 299
 micro-determination of by calorimetry 165
 per se and caffeine beverage effect of on reaction
 time in young adults, 84
 Cal B, 256
 Colbrolact 356
 Colchicronol chemical experience with 192
 Calcidex 256
 Calcidrine 39
 Calciferal treatment of law colicium tetony with 345
 Calcinate 256
 Calcio-caramine 256
 Calciphas 39
 Calcium availability of in foods containing oxolotes
 289
 and phosphorus analysis digesting biological mate-
 rials for 217
 aurthasulphates preparation and properties of 6
 chloride solutions effect of sterilization af 153
 campounds comparative study af the absorbability
 of 137
 Eci 256
 far injection 235
 glucanate stable solutions af 55
 glycerophosphate analysis af 62
 hydraxide solubility and determination af 218
 hypochlorite some observations on the germicidal
 efficiency af 269
 hypochlorite value af as volumetric oxidizing agent
 stability and standardization of determination af
 ammonia 62
 in serum volumetric determination of 289

studies of crystalline VIII sulphite cleavage II chemistry of the acidic product 164
- B₂ condition of in cows milk 61
(lacto flavin) isolation of from hay 58
phosphoric acid synthesis of 61
- Vitamin C comparison of oral and subcutaneous administration of protective doses of 241
and diphtheria toxin 155
(ascorbic acid) inactivation of diphtheria toxin in

- and *in vitro* by crystalline 153
 in bulk 8
 influence of on development of skin sensitivity to
 neoursphenamine in guinea pig 88
 (ascorbic acid) sensitive spot reaction for 118
 titrimetric assay of 19
 Vitamin D absorption of through the skin 197
 content of in salve bases containing cholesterol I
 absorption through the intestinal mucosa 190
 determination of 190
 transformation of highly potent physiological prod-
 ucts with ultraviolet rays 61
 Vitamin E vestibular function test for deficiency in the
 rat 139
 capsules multine 152
 standards international 117 191
 synthesis 164
 Vitamins 164
 Vitamins A and D and camphor oil use of in the treat-
 ment of burns 354
 Vitamins B experimental investigations on in their
 relations to glucides proteins and lipids of diet
 60
 history of the discovery of 164
 standardization of report of Second International
 Conference 117
 Volatile oils and aromatics advances in the field of
 in 1933 ketones 102
 Vulvo-vaginitis treatment of with oestron 91

W

- War gases detection of 316
 Water bacteriological control of 47
 sterilization of by a new quartz lamp 232
 Wax paraffin nmpuls use of for silver nitrate used in
 prevention of ophthalmia neonatorum 324
 Waxes, acid indices of 214
 heating of and fats 23
 Weihe Wiener Eisenpillen 152
 Wei ling sein studies on 159
 White liniment suggested formula for 78
 mineral oil and petrolatum use of in pharmaceutical
 and cosmetic practice 130

- Whooping-cough control of with serum and vaccine,
 273
 cough immunization against 47
 cough significance of bacteriological methods of
 diagnosis and control of 47
 Wine effect of cold and freezing storage on the com-
 position of 24
 Witeb Hazel (hamamelis) extract and distillate
 history of 80
 Witham obtusifolia V tuck and W somnifera dunal
 226
 Wolarrin tablets 203

Y

- Yntren sterilization of gauze containing 322
 Yeast extract suggested test for distinguishing be-
 tween and meat extract 14
 Yeasts quantitative determination of biological value of
 medicinal 30
 Ylang oils classification of commercial 274
 composition of commercial 316
 non modification of the sympatholytic action of
 by the introduction of a double bond 340

Z

- Zephriol new disinfecting agent 37
 Bayer use of in pharmaceutical practice 324
 use of in the preparation of sterile solutions for injec-
 tion 98
 Zinc estimation of and its separation from manganese
 127
 estimation of in presence of iron aluminum ura-
 num beryllium and titanium 316
 microdetermination of by means of anthranilic acid
 317
 oxide and olive oil mixtures of 181
 Zirconium use of *n*-propylarsonic acid as a reagent
 for the determination of 16
 Zittmangan 45
